POISONING OF TRAINING-SHIP "CUMBERLAND" BOYS NEAR HELENSBURGH.—On the 11th inst., while a number of boys belonging to the training-ship *Cumberland* were sent out for their usual morning exercise, they commenced gathering roots and herbs which were strewn along the shore. One of them, believing the herb to be harmless, commenced eating it, and his companions followed his example. Shortly afterwards ten of their number complained of sickness, and before they could return to the ship three of them fell into a kind of stupor, and lay helpless in the road. They were carried into a neighbour's house, where some warm milk was procured, but the lads gradually grew worse, as did also several others. Four of their number were immediately conveyed in a cab to Helensburgh, where they were attended by Dr. Reid, who ordered their removal to the Infirmary. Everything was done to produce nausea, and to prevent them from falling into a stupor, but despite the efforts of the medical men they remained in an unconscious condition for upwards of five hours. The remaining six were taken on board the ship, where they were duly tended, but in the course of the afternoon it was found necessary to send one of them to the Helensburgh Infirmary. These five were in a critical condition for some time, one of the cases being almost hopeless; fortunately, all are now out of danger. The herb is a deadly poison of the hemlock class, having a strong fibre running through the stem. The event has caused great excitement in the neighbourhood.

GLASGOW OPHTHALMIC INSTITUTION.—The fifteenth annual general meeting of the donors and subscribers to the Glasgow Ophthalmic Institution, which owes its origin to the business ability of Dr. Wolfe, was held on the 10th inst., in the Merchants' House, Glasgow, Bailie Hamilton presiding. Sir James Watson, before beginning the business of the meeting, referred in fitting terms to the loss the institution had sustained by the death of their chairman, Mr. James White. The secretary submitted the annual report, which stated that, in addition to a considerable number of patients remaining on the books at the beginning of the year, 3,012 new cases had been admitted, of which 2,627 were dispensary patients, while 385 had been taken into the hospital

for treatment—an increase of 8 indoor patients as compared with the previous year. The average period of each patient's residence in the house had been 22·7 days, as against 21·1 last year. The number of patients dealt with since the opening of the institution in 1870 had been 43,730, and of these 42,189 had been dismissed cured or relieved. Of the 3,012 cases treated during the year, 2,876 had been cured, 84 relieved, and 52 had been dismissed as incapable of further benefit. The income for the past year had been £1,346 19s. 8d. On the motion of the Chairman, seconded by Sir James Watson, the report was approved.

MORTALITY IN GLASGOW.—The deaths in Glasgow for the week ending with Saturday, the 8th inst., were at the rate of 27 per 1,000 per annum of the population, as compared with 28 in the previous week, and 31, 25, and 29 in the corresponding periods of 1883, 1882, and 1881 respectively.

HEALTH OF EDINBURGH.—The mortality in Edinburgh for the week ending with Saturday, the 8th inst., was 90, and the death-rate 19 per 1,000. Diseases of the chest accounted for 50 deaths, and zymotic causes for 7, of which 2 were due to fever, 2 to diphtheria, 1 to scarlatina, and 2 to measles, the intimations of these diseases for the week being 6, 4, 38, and 85 respectively.

THE PROFESSION AT THE LEVEE.

By command of the Queen a levée was held on Monday afternoon, at St. James's Palace, by his Royal Highness the Prince of Wales, on behalf of her Majesty, presentations being at this Court, by the Queen's pleasure, considered as equivalent to presentations to her Majesty. The following members of the profession had the honour of presentation:—Sir W. Guyer Hunter, M.D., on being made a K.C.M.G.; Sir Richard Owen, on being made a K.C.B.; Sir Hy. A. Pitman, M.D., on being made a K.C.B.; Deputy Surgeon-General E. F. O'Leary, M.D.; Acting Surgeon Jas. Reid, M.D., Gordon Highlanders; Reginald Southey, M.D.; Surgeon P. W. Bassett-Smith, R.N.; Surgeon Hy. J. Wyatt, A.M.D.; Surgeon-Major Lloyd-Barrow, M.D.; and Dr. Theodore Acland.

ANALYSIS OF THE MEDICAL BILL.

Read a second time in the House of Lords, March 6th. To be Committed March 20th.

In this Analysis of Bill all the important phrases are printed verbatim.

(Continued from page 241.)

The following is an analysis of the clauses of the Bill additional to those which we published last week:—

PART III.

Colonial and Foreign Practitioners.

22. A person holding a recognised colonial diploma, and being authorised to practice in the British possession in which he resides shall be entitled, without examination, to be registered as a colonial practitioner:

Provided—

- (1.) That he has practised medicine in the United Kingdom for the preceding ten years; or
- (2.) That his diploma was granted to him when he was not domiciled in the U. K.

23. Same enactment as regards foreign practitioner;

Provided—

- (1.) That he is not a British subject; or
- (2.) That being a British subject his diploma was granted when he was not domiciled in the U. K.
- (3.) That being a British subject he has practised in the U. K. the ten preceding years.

24. The recognised medical diplomas shall be such medical

diplomas as may be recognised by the Medical Council "as furnishing a sufficient guarantee of the possession of the requisite knowledge and skill for the efficient practice of medicine, surgery, and midwifery, and as entitling the holder thereof to practise medicine, surgery, and midwifery in such British possessions or foreign country."

It is deserving of serious consideration whether foreign diplomas should be registered in the United Kingdom, considering that certain foreign countries, including France, refuse reciprocity under any circumstances. It is indeed obvious that the Medical Council has, or can have, at its disposal no adequate means of forming a judgment as to whether any particular foreign degree furnishes "sufficient guarantees for the possession of the requisite knowledge and skill for the efficient practice" of the profession, as required by the section, for it must be evident that a mission of a visitor from the Medical Council to inspect an examination in Ohio or Moscow would be utterly impossible, and, if possible, quite futile, inasmuch as such an inspection would not afford the least guarantee that the examination which was adequate at the particular occasion when it was inspected would continue to be so. Moreover, the Medical Council, having once recognised any foreign diploma, could not revoke that recognition without the approval of the Privy Council; and it would be plainly impossible for the Medical Council, even if disposed to trouble itself about the matter, to collect such evidence of the insufficiency of the examination as would justify the Privy Council in revoking the recognition. As a matter of fact, we know that the Medical Council has recognised as sufficient the preliminary examinations held by certain antipodean bodies, of which it knew absolutely nothing, except from the *ex parte* assurances of those bodies themselves; and it would be nothing less than calamitous to the profession if it acted upon the same principle in reference to medical diplomas, and admitted to practice in Great Britain a host of diploma-holders from obscure American and Continental qualifying bodies.

The words of the Bill prohibit the registration of any diploma which does not "entitle the holder thereof to practise medicine and surgery in such British possession or foreign country." This proviso would be a perfectly sufficient protection for us in the case of diplomas issued (as in Germany) after a "Staats Examen," or with a Government impress, but in other places, as in America, any or every diploma entitles the holder thereof to practise, and the phrase of the Bill would, therefore, afford us no protection whatever against Canadian or American diploma-holders.

The proposition contained in the Marquis of Ripon's Bill of 1871, is much preferable. It provides that the foreign medical diploma must "represent the like degree of knowledge, as tested by examination, to that which is required for a licence" in Great Britain. The present Bill, on the other hand, recognises any foreign diploma which "furnishes sufficient guarantees of the possession of the requisite knowledge and skill," a phrase which would enable the Medical Council to register any low-class foreign degree it pleased.

The Marquis of Ripon's Bill recognised only such foreign degrees as were granted under "the authority of the Government of a British possession or foreign country"—a very different proposition from the recognition of every diploma which confers the right to practise in its own country, which is suggested by the Bill.

Recognition of foreign and colonial degrees should not be without—1. A distinct guarantee of the country in which the diploma is granted. 2. A degree of knowledge, so far as the Medical Council can judge, equivalent to that required for the conjoint examination at home. 3. The consideration of the Medical Council of each particular application for registration.

PART IV.

Quacks' Clauses.

26. Any registered practitioner who now holds, or may hereafter obtain, a recognised medical diploma, or who, being on the Register of foreign or colonial practitioners, shall have obtained a recognised colonial or foreign diploma, to cause a description of such diploma to be added to his name in the Register, and to use any medical title which such diploma authorises.

This clause is greatly complained of, because it does not give the State examinee any registrable title independent of his collegiate diploma. As the Bill originally stood it authorised him to call himself "Licentiate of the Medical Council," and to practise under that name, but that provision was struck out for the purpose of inducing, though not coercing, the student to take the diploma of a licensing body. As the Bill now stands the State examinee would appear in the Medical Register as a recognised practitioner; he would enjoy all the consequent privileges, but he would not possess any distinctive title unless he had also taken a diploma or degree, which would be appended to his name in the Register. We recognise that such a proposition is bad in principle, but we think that, under all the circumstances, the want of a title would be met in a better way by requiring the student to attach himself to a licensing body throughout his period of study, and to subsequently obtain its diploma as indispensable to registration, than by giving him a title independent of some such body. This we have advocated in our commentary on Clause 3. The reasons for this "affiliation" are twofold. It would place the student under control and supervision from the first—would impel the licensing body to devote itself to educational work—would maintain a certain amount of control over the licentiate after he entered practice—would provide a *modus vivendi* for the licensing bodies who are to be the motive power of the future examinational system—and would remove most of the difficulties as to division of surplus funds under the Bill.—Note our commentary on Clause 3, in last issue, and Clause 34, below.

27. (1.) If any person, whether registered or not, uses a medical title which he is not entitled to use, a penalty of twenty pounds.

(2.) If any person, whether registered or not, takes or uses a medical title which is by this Act not Registrable, penalty twenty pounds:

Provided that a person shall not be liable—

If he is not ordinarily resident in the Kingdom, and holds a diploma which authorises him to use the title complained of, and to practise in the country in which the diploma was granted.

(3.) If any person not registered represents himself to be a registered medical practitioner, or uses any name, title, addition, or description implying that he is a registered medical practitioner, penalty, twenty pounds:

(4.) If any person who is not registered, and who practises for gain, or professes to practise, or publishes his name as practising medicine or surgery, or who receives any payment for practising medicine or surgery,

(a) represents himself to be a physician, surgeon, doctor, or apothecary; or

(b) uses any designation denoting that he is qualified by law to practise, penalty, twenty pounds.

These clauses as they stand make no provision for preventing ignorant and unlicensed persons from practising medicine and surgery, and receiving fees for medical services rendered. They are limited to prohibiting the use of certain medical titles. The Bill will, we fear, open the door to unlimited practice by unqualified persons in England, because it repeals the Apothecaries (England) Act of 1815, which is the only enactment now existing under which such persons can be prosecuted)

(5.) Prosecutions for these offences may be undertaken only

- (1.) By a person authorised by the Medical Council; and
- (2.) By the Prosecutor, or by a person authorised by the medical board for same, or by a recognised medical authority.

This clause, as it stands, is objectionable, because it will throw a shield before all quacks, and make their punishment very difficult. It forbids the prosecution of an unqualified person without the assent of the Medical Council or of the Public Prosecutor, and it puts no obligations whatever on either of these parties to institute these prosecutions on their own behalf. Considering that the permission of the Public Prosecutor could not probably be obtained—if granted at all—without great expense and delay, and considering that the Medical Council has repeatedly declared that the prevention of unlicensed practice is no part of its business, it is obvious that these clauses, if passed without amendment, will be a protective for all quacks. This restriction, which would prevent individuals or professional organisations from prosecuting quacks, is the less justifiable because a different enactment is proposed in the Bill with regard to prosecution of unqualified dentists. Clause 70 of this Bill enacts that the restriction which is here proposed shall be removed in the case of dentists, and it is difficult to conceive why the legitimate practice of a speciality should be less protected from the invasion of quacks than the legitimate practice of medicine and surgery generally.

This section shall not prevent

- (1.) A person from using the designation of midwife, or
- (2.) A person holding a licence in midwifery from using the designation of licentiate in midwifery, or
- (3.) A registered dentist from using any title which he is entitled to take or use under the Dentists' Act.

Management of Register.

28.—(1.) The Medical Register shall contain the names and addresses—

- (a) Of all persons who are now registered practitioners, and of all persons who afterwards may become entitled to be registered by reason of final examination; and
- (b) Of such colonial and foreign medical practitioners as are entitled to be registered under this Act;

The names shall be divided into three lists—home, colonial, and foreign practitioners.

Where the Medical Council is of opinion that the erasure of the name of a person from the Register will be too severe a punishment for the offence of such person, they may, instead of directing his name to be erased, declare that he is suspended, and thereupon directing the word "suspended" to be entered opposite his name in the Register.

A registered medical practitioner when suspended shall not be deemed during such suspension to be a registered medical practitioner.

The name of a person shall not be erased nor suspended under this section—

- (a) For adopting the practice of any particular theory of medicine or surgery, nor
- (b) For a conviction for a political offence abroad, nor
- (c) On account of a conviction for an offence which does not, either from the trivial nature of the offence, or from the circumstances under which it was committed, or from the time which has elapsed since its commission disqualify a person in the opinion of the Medical Council.

It will be observed that, by these clauses, the Medical Council seeks new powers to condone offences against the profession. Under the existing law a person guilty of "a felony, or misdemeanour, or of infamous or disgraceful conduct in a professional respect" is liable to have his name removed from the Register. The Council now seek powers to mitigate the punishment of such persons, and to "suspend" them from legitimate practice for a short time; but by sub-clause (c) it also seeks power to give such persons a free pardon and retain their names on the Register, or restore

them thereto. Considering that the Council permitted the name of the murderer Lamson, and others nearly as guilty to defile the Register (though their attention was officially called to the matter)—that they placed on the Register more than one person who has served his time in penal servitude, and that they refused to erase the name of a dentist, although they had a few minutes previously declared him guilty of "infamous and disgraceful conduct," it seems needless to urge that as little as possible option should be allowed to them.

Medical Authorities.

34. Any medical authority may grant medical diplomas to persons of both sexes, provided that—

A woman shall not be thereby entitled to any share in the management of that authority.

35. Any authority may admit to its lowest qualification without further examination, any person who has passed a final examination.

This is an important proviso in regard to the affiliation of the state examinee to a licensing body (as proposed in our note to sec. 3) because it enables such bodies to accept the examination of the Local Boards as equivalent to their own, and to give their license to their alumni without further examination or fee.

It would be very desirable if it could be enacted that every licensing body—having passed the student through its non-primary examinations and through the final examination of the State Board—should be bound to grant its diploma without further examination and at a nominal fee. Thus the student would be provided—by virtue of his State examination—with a registrable title. Two impediments exist to prevent this being done—*a.* Certain bodies refuse to admit women to their diplomas on any terms; *b.* The higher Universities object to grant their degrees on the final examination or any other examination not held by themselves.

PART V.

Expenses and Medical Funds.

38. The three medical boards and the Medical Council shall respectively form funds.

Under the Bill two sorts of funds are contemplated—*a.* Three local medical board funds, resulting from the surplus of the fees paid to local boards for final examination, over the expenses of same; *b.* A Medical Council fund, resulting from the assets from the three existing Branch Councils, plus the fees of £5 each for registering practitioners when fully qualified.

(4.) The expenses of maintaining any such medical museums and medical libraries belonging to any medical authority as may before the passing of this Act have been ordinarily maintained for general public purposes by such authority in their capacity of grantors of qualifications for registration under the Medical Act, 1858, and have been so maintained out of fees paid by applicants for such qualifications, and may be of such importance to the promotion of knowledge in medicine or surgery as to deserve to be maintained out of the funds of the Medical Council.

This clause is open to many objections. In the first place it makes the maintenance of Colleges, &c., depend on the local funds, from which there may possibly be no surplus, inasmuch as the final examination fee may possibly not be more than would cover the cost of examination. In the second place, it makes no provision for the maintenance of institutions, but only for the "medical museums and libraries" kept up by them. In the third place, it is complicated, and not applicable generally, and seems to have been originally framed to meet the case of the Hunterian Museum.

The Medical Council fund shall be applied in payment of—

(1.) The reasonable expenses and remuneration to members of the Medical Council.

(2.) Expenses in respect of officers and rooms, &c.

(3.) The expenses of the election of direct representatives. Any surplus shall be applied "for the benefit of the medical profession, or in such manner as the Medical Council may determine."

Fund *b.* (the general fund) would be large. It would start with the aggregate capital of the three existing Branch Councils (£29,000 + £2,000 + £1,869), amounting to £32,869, and yielding an interest income of nearly £2,000 a year. It would have also an income of almost £6,000 arising from registration of practitioners, and against this total income of £8,000 it would expend for the Medical Council and its establishment about £3,500, leaving a yearly profit of about £4,500 available for any purposes within the wide area of the phrase quoted above.

This large fund would be allocated at the unlimited discretion of the Medical Council, which would be a very unwise method of distribution.

In principle all surplus funds accruing from examination or registration should, after satisfaction of the demands upon them for maintenance of the central and local supervising bodies, be allocated for the sustentation of medical education, and to the support of educational bodies in proportion to the public work which those bodies are performing. Therefore, in our opinion, the whole of the surplus from examination and registration should go to a general fund, and, at the end of the year, should be distributed by the Central Council to the three divisional boards in proportion to the number of candidates passed by them, and should be again distributed by each divisional board to educational bodies recognised by it, in proportion to the output of licentiates and the other public work done by each such body.

Some estimate of the share of each divisional board under this arrangement may be formed by calculating from the Students' Register the part taken by England, Ireland, and Scotland in medical education. Taking the three years last past, we find that an average of 2,048 new students were registered each year throughout the Kingdom, of whom

England	supplied	966	annually;
Scotland	"	580	"
Ireland	"	502	"

Total 2,048

Calculating on this basis, which we admit is not the only element in the calculation, and dividing the gross central surplus fund into hundredths, it appears that, in respect of its medical educational work, the English divisional board should receive 47.1 per cent. of the entire fund, Scotland 28.3, and Ireland 24.5.

In estimating the fees to be charged for final examination a distinction shall be made between so much of the fee as is leviable for the purpose of administrative expenses of the board and so much for expenses of the maintenance of museums and libraries; and the fees to be paid by University graduates or undergraduates holding University certificates of having passed the examinations at their University qualifying for admission to the final examination of the board shall not exceed the former portion of the fee.

This clause is intended as an expression of the recommendation of the Royal Commission that students educated in Universities should not be called upon to pay for maintenance of the teaching establishments of other institutions from which such students are said to have derived no benefit, it being arranged that in consideration of this special exemption from fee the Universities to which such students belong should not claim any share of the local Board surplus fund (*a*)

above referred to. This concession to Arts graduates or to undergraduates of at least three years' standing is reasonable; but we altogether dissent from the proposition to extend such privilege to students who are only University graduates in name, and who have not acquired a claim—by *bona fide* academic studies—to the enjoyment of such privileges. A marked distinction must be drawn between Universities such as Oxford, Cambridge, and Dublin, which accept no candidate for their medical degrees but those who have fulfilled a complete curriculum in Arts as well as in Medicine, and those other Universities which grant their highest medical degrees to students who are little more than matriculants, who pass but one, or, at most, two preliminary examinations of no higher standard than the analogous examinations of Colleges—who are examined, but not in any respect educated in these Universities—who do not reside therein, and who are not called upon to pay the cost of complete Arts studies. Such Universities, being simply examination centres, have even less claim to special privileges than those Colleges which both educate and examine and which maintain for purely public purposes an educational establishment of the greatest value without calling upon the public purse for any assistance.

PART VI.

GENERAL PROVISIONS.

As to Medical Boards, Medical Council, and Privy Council.

38. Each medical board may, with the assent of the Medical Council, appoint and remove a secretary, treasurer, and such other officers and servants as the medical board may require.

39. The Medical Council may from time to time, with the sanction of the Privy Council, do likewise.

As to the Approval and Confirmation of Schemes.

41. Where a scheme is required to be approved by the Medical Council—

- (1.) The medical board shall send a copy to the Medical Council.
- (2.) The Medical Council may either annul or approve the same with or without modification made by the Council, or may remit the same to the medical board for modification by them, until it is brought into conformity with the views of the Medical Council.
- (3.) The Medical Council to forward as soon as practicable to the Privy Council for confirmation any scheme approved by the Medical Council.
- (4.) The Privy Council shall take the same into their consideration, and may either annul the same altogether, or may remit the same to the Medical Council for modification by them.

The Medical Council before approving and the Privy Council before confirming any scheme shall hear any objections which may be made to the scheme by any person or body of persons.

These Clauses would all need alteration if the making of the scheme of education and examination were remitted to the Medical Council instead of the respective medical boards, as we have strongly advocated in our comments on Clauses 18 and 19. We repeat that equality of educational standard throughout the Kingdom can never be attained. . . if the three boards are authorised to make three different schemes of different educational standards.

42. If any medical board makes default in the performance of its duty, the Medical Council shall notify to the medical board that it has made such default, and may by order suspend or supersede such board, and direct a fresh election to be held.

43. If the Medical Council makes default in the performance of its duty, the Privy Council shall notify that it has made such default; and the Privy Council may do any

act or thing in respect of which it considers the Medical Council to have been in default.

PART VII.

Transition from Old to New Law.

54. The first election of each medical board shall take place in January, 1885.

Each medical board shall come into office on Feb. 1, 1885. The first meeting shall take place within the first fortnight in February.

For election of direct representatives, the medical registrar shall issue his precept to each medical board, requiring such board to cause the members to be elected within fourteen days, as follows:—

- (1.) The nomination paper of each candidate shall be signed by twelve registered practitioners; and
- (2.) The returning officer shall forward by post to each registered medical practitioner a voting paper.

The first Medical Council shall come into office on April 30, 1885, and its first meeting shall take place during the first fortnight in April.

55. Each medical board shall, before August 1, 1885, submit to the Medical Council a schema. See note on clauses 18 and 41.

The scheme so submitted shall be settled by the Medical Council and forwarded to the Privy Council before Jan. 1, 1886.

Any objections to such scheme shall be considered by the Privy Council before November 1, 1885.

The first final examination shall be held not later than the 1st of March, 1886.

56. Branch Councils shall cease to exist, and all their property shall be transferred to the Medical Council. See our note to clause 38.

58. The existing officers of the Branch Council shall become officers of the Medical Board for their own division of the Kingdom.

This clause should not be permitted to pass, for it would provide the Medical Board at starting with, in some cases, officers entirely unfit for the new duties.

PART VIII.

Saving Clauses.

67. Nothing in this Act contained shall in any way prejudice the lawful occupation of chemists, or druggists, or so far as relates to selling, compounding, or dispensing medicines, the rights, privileges, or employment of duly licensed apothecaries in Ireland.

68. Nothing in this Act contained shall prevent any person not a British subject who has obtained a foreign degree or diploma entitling him to practise medicine, surgery, and midwifery in his own country, from acting as the medical officer of any hospital for the relief of foreigners in sickness, although he is not registered as a foreign practitioner, provided that such person is engaged in no other medical practice.

69. Nothing in this Act contained shall repeal or alter any of the provisions of the Passenger Act, 1855.

70. This Act shall not increase or diminish the privileges of any person who, on December 31st, 1884, is a registered practitioner, and such person shall be entitled to practise in medicine, surgery, and midwifery, or in any one or more of them, according as he was entitled to practise in such callings or any one or more of them, before the said appointed day, but not further or otherwise.

Dentists.

72. There shall be repealed so much of the Dentists' Act as provides that a prosecution shall not be instituted by a private person, and a prosecution for any such offences may be instituted by a private person accordingly. See our note to clause 28.

SCHEDULE.

PROCEEDINGS OF MEDICAL BOARD AND OF COMMITTEES OF MEDICAL BOARD AND MEDICAL COUNCIL.

1. The board or council shall from time to time make such regulations with respect to the transaction and management

of business as they think fit, subject to the following conditions :—

- (a) An extraordinary meeting may be summoned at any time on the requisition of three members addressed to the chairman ;
- (b) The quorum shall consist of not less than three members ;
- (c) Every question shall be decided by a majority of votes of the members present and voting on that question ;
- (d) The names of the members present at a meeting, and upon a requisition made by any member or members voting on a question, the names of the members voting on that question shall be recorded.

2. In case of an equality of votes at any meeting the chairman for the time being of such meeting shall have a second or casting vote.

Correspondence.

LIABILITY OF HOSPITAL PHYSICIANS AND SURGEONS FOR MAKING POST-MORTEM EXAMINATIONS.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—In your editorial remarks upon the post-mortem examination in this hospital (which lately formed the subject of a coroner's inquest), you correctly state the present condition of the law. I have the most eminent advice that there is no property in a dead body ; and that, as the law does not take cognisance of injured feelings, no action for damages can be sustained. This view is supported by English decisions.

The idea of compromising this action never entered into my mind. I believe that if I were to pay even one farthing to settle it I would be purchasing freedom from annoyance by the sacrifice of principle and the betrayal of professional right. On the contrary, my solicitor has been instructed to defend it to the end, and of that end there can be no possible doubt.

The Great Ormond Street case, this time two years, established that no criminal prosecution can be sustained for the making of a post-mortem examination. The present case will establish that, neither in the coroner's court nor in any civil tribunal, is there any legal remedy against a physician for making a post-mortem examination with propriety, and for the legitimate advancement of the medical art. The establishment of this principle here is of great importance to the profession ; and the attainment of it will more than compensate me for the annoyance which I have received for doing what I still believe to have been my simple duty.

Yours, &c.,

F. J. B. QUINLAN, M.D., M.R.I.A.,

Fellow of the King and Queen's College of Physicians.

St. Vincent's Hospital,
March 12, 1884.

Obituary.

MR. JOHN DOUGAN, OF GLASGOW.

We deeply regret to have to record the death of Mr. John Dougan, surgeon, Glasgow, which took place at his residence in Hillhead, on the 12th inst. The deceased was a little over sixty years of age. He studied his profession at the University of Glasgow, and became a Licentiate of the Glasgow Faculty in 1845, since which time he practised in Glasgow, where he was well known and respected for his sterling honesty, pawk Scotch humour, and intellectual attainments. Mr. Dougan was an excellent mathematician and Latin scholar, accomplishments now becoming rare amongst medical men. The former of these studies afforded him solace almost to his death-bed. In politics he was an intellectual Liberal, and his religion was what Froude calls "that of all sensible men." He was much beloved and respected by his patients, and his burly form and honest face will long linger in the memories of the inhabitants of the north-western districts of Glasgow.

Medical News.

The Dental Hospital of London.—The 26th annual meeting of this Institution was held at the Hospital on Wednesday last, under the presidency of Mr. John Eric Erichsen, F.R.S., one of the vice-presidents. In the report, which was unanimously adopted, the continued success and prosperity of the Institution and the great benefits which the Hospital continues to afford to the suffering poor, 35,622 cases having been treated during the year 1883, were adverted to, and the gift of a new wing by Sir Edwin Saunders for the purpose of enlargement was gratefully acknowledged. In order to obtain the funds necessary for fitting up and adapting the new wing, and for redeeming the mortgage debt of £5,000 on the Hospital building, a special appeal had been issued, and the sum of £1,132 4s. had been received in response. There is still a deficit of £3,865 6s. 6d. in the Extension Account, and the Committee are compelled to make a further special appeal for the funds necessary to pay off this debt, which presses so heavily upon the charity and materially curtails the benefits it would otherwise be enabled to confer upon the suffering poor.

Medical Sickness Annuity and Life Assurance Society.—A meeting of the Provisional Executive Committee of this Society was held at 88 Wimpole Street, W., on Thursday, March 6th, Mr. E. Noble Smith, F.R.C.S., in the chair. The following members were present :—Mr. Sibley, Surgeon-Major Evatt (Woolwich), Dr. Clibborn, Mr. Brindley James, Mr. Major Greenwood, jun., Mr. Rasley, (Sec.). The minutes of the last meeting were read and passed. The Secretary presented his report, showing that 800 members had joined them, and that the receipts amounted to £185 7s. 2d. The report was received and adopted. The Chairman stated that a letter had been received from Mr. Ernest Hart expressing his satisfaction at the progress of the Society, and making suggestions with regard to its further extension which were unanimously approved. The Secretary recommended that as it had been decided after consultation with their consulting actuary, Mr. Neison, to accept members for sick pay and annuity combined, that the two funds be kept distinct, and that separate tables be drawn and printed showing the rates for sick pay only. This was duly proposed and carried. A letter was read from Mr. Parsons (Ambleside) asking whether gentlemen retiring from practice after becoming members of the Society were open to receive the benefits of the Society, an answer was directed to be sent in the affirmative. A communication was read from a correspondent who desired to know if members of the army and navy medical services who were liable to be called out of the country on duty, would be eligible as members of the Society. It was decided to reply that the Society was too young to undertake the risks this would involve. The question of holding a general meeting in London was discussed, and its further consideration deferred. A discussion arising out of questions connected with the proposal forms referred to the meeting brought the proceedings to a close.

OPERATION DAYS AT THE LONDON HOSPITALS.

MONDAY—Hospital for Women, 2 p.m.—Metropolitan Free, 2 p.m.—Royal London Ophthalmic, 11 a.m.—Royal Orthopaedic, 2 p.m.—Royal Westminster Ophthalmic, 1.30 p.m.—St. Mark's, 2 p.m.

TUESDAY—Cancer Hospital, Brompton, 2 p.m.—Guy's 1.30 p.m.—St. Mark's, 9 a.m.—Royal London Ophthalmic, 11 a.m.—Royal Westminster Ophthalmic, 1.30 p.m.—Westminster, 2 p.m.—West London, 3 p.m.

WEDNESDAY—Great Northern, 2 p.m.—London, 2 p.m.—Middlesex, 1 p.m.—National Orthopaedic, 10 a.m.—Royal London Ophthalmic, 11 a.m.—Royal Westminster Ophthalmic, 1.30 p.m.—Samaritan Free Hospital for Women and Children, 2.30 p.m.—St. Bartholomew's, 1.30 p.m.—St. Mary's, 1.30 p.m.—St. Peter's, 2 p.m.—St. Thomas's, 1.30 p.m.—University College, 2 p.m.

THURSDAY—Central London Ophthalmic, 1 p.m.—Charing Cross, 2 p.m.—Hospital for Diseases of the Throat, 2 p.m.—Hospital for Women, 2 p.m.—London, 2 p.m.—North-west London, 2.30 p.m.—Royal London Ophthalmic, 11 a.m.—Royal Westminster Ophthalmic, 1.30 p.m.—St. George's, 1 p.m.

FRIDAY—Central London Ophthalmic, 2 p.m.—East London Hospital for Children, 2 p.m.—Guy's, 1.30 p.m.—King's College, 2 p.m.—Royal London Ophthalmic, 11 a.m.—Royal South London Ophthalmic, 2 p.m.—Royal Westminster Ophthalmic, 1.30 p.m.—St. Thomas's (Ophthalmic Department), 2 p.m.

SATURDAY—King's College, 1 p.m.—London, 2 p.m.—Royal Free, 9 a.m. and 2 p.m.—Royal London Ophthalmic, 11 a.m.—Royal Westminster Ophthalmic, 1.30 p.m.—St. Bartholomew's, 1.30 p.m.—St. Thomas's, 1.30 p.m.

Notices to Correspondents.

SURGEON-GENERAL FRANCIS will please receive our best thanks; he will see that the information has been utilised in another column.

DR. CLIFFORD ALLBUTT.—The instructions shall receive our best attention.

MR. LAWSON TAIT is thanked for his communication, which is much appreciated, and will appear in the earliest possible number.

MR. POWER.—The case will be sent in course of post.

MR. R. F. G. (Melbourne).—We have now a considerable sprinkling of subscribers in the colony. Since your note was written we have appointed an agent for Australia, Mr. Bruck, of Sydney, to whom you can in future pay your subscription, as well as that for your friend at Brisbane to whom you kindly introduced the journal.

DYNAMITE AND MEDICAL ASSISTANTS.

To the Editor of the MEDICAL PRESS AND CIRCULAR.

SIR,—I wish to call the attention of your readers, and especially those hailing from Ireland, to a condition of things which it is important that they should know.

No one who knows me can have any doubt as to the direction of my sympathies, and I trust that I need not say that I do not share the prejudice to which I refer; but I wish to state what that prejudice is, namely, that in consequence of what are called "Irish outrages," dynamite explosions, and so on, gentlemen requiring assistants will not employ Irishmen, no matter what their qualifications or antecedents. A principal, who had come up from the country, and who appointed to meet certain assistants at my office, expressed himself as highly pleased with the gentlemen to whom I had introduced him, but added: "I dare not take an Irishman home with me; my wife would think that she had the smell of dynamite always under her nose." What can be done? I can only recommend patience to live down the prejudice, and express regret that a body of educated gentlemen should be made to suffer for the sins of an unprincipled set of paid agitators.

Yours, &c.
50 Lincoln's Inn Fields, London, W.C., J. BAXTER LANGLEY.
March 11, 1884.

MR. REGINALD HARRISON'S "Case of Ruptured Bladder and Fractured Pelvis" shall appear, if possible, in our next.

MR. WILTON.—We have not seen the report in local paper referred to. We receive dozens of newspapers weekly, correspondents rarely marking the portion to which they desire to draw attention; consequently, in a necessarily hurried glance, many matters are overlooked through this omission on the part of the senders.

SCHOOL HYGIENE.

At a special general meeting of the Committee of the National Health Society, on Thursday last, for the purpose of considering the desirability of establishing a conference on "School Hygiene" during the International Health Exhibition, it was arranged that papers on various topics relating to school life and training should be read, and discussion invited. All those interested in the subject are requested to communicate with the Secretary.

A SANITARIAN.—The body over which the customary drunken orgies were held was not removed for the occasion from one of the metropolitan asylums; on the contrary, the person died in the City of London Infirmary. The managers of the Asylums Board are very particular in this respect, and do not, under any circumstances, allow the bodies of patients dying in their hospitals to be removed until the day of interment, when the bodies are removed direct from the hospitals to the cemetery.

HARD AND FAST.—The line you so strongly object to is likely to be loosened by pending legislation. In our last issue we devoted space to an epitome and editorial consideration of the new Bill to the end of Part II. In our present number we conclude our Analysis of the Bill in all its bearings, and hope thus to have facilitated its study by our readers.

DISPENSARY MEDICAL OFFICERS AS J.P.'S.

ALPHA asks: 1. Can a dispensary medical officer become a J.P.? 2. Is there a property qualification necessary?

[1. Yes, there are many J.P.'s holding dispensaries. We hope to publish a list next week. 2. No.—ED.]

IN MEMORIAM.—Your intention has already been anticipated, and a movement is now on foot to collect an amount sufficient to provide for those dependent on Mr. Wheatley, and who are left most slenderly off. At the Clinical Society, on Friday last, the President announced that the Council of the Society had voted a sum of £25 to the fund, and appealed to members to add their individual contributions.

R. L. W.—Numberless suggestions of articles disguising the smell of iodoform have been made from time to time. The most recent are attar of rose, one drop to a drachm; and oil of citronella. Peruvian balsam also is said to be effectual in this respect; and several other substances.

MR. JAMIESON.—Unless there is palpable evidence that the child is suffering from the irritation of the tooth, it is as well to abstain from interference. If, however, the gum presents indications of inflammation, &c., then it is advisable to relieve it at once by making an incision over the projecting tooth. If it be a molar, the incision should be crucial in form. Hyd. c. cret. with Dover's powder is a useful prescription.

DR. ANDREWS.—The work has not yet been published in this country, but it is not unlikely that an English edition will be announced before long. The arrangement would not be a favourable one on the terms you have mentioned. It would be wiser to consult someone with special experience.

MR. CONSTANTINE.—It is most improbable that any notice would be taken of any proceedings so directly opposed to good taste and justice. You will consult your patient's interest best by letting the subject drop.

Meetings of the Societies.

WEDNESDAY, MARCH 19TH.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—At 4 p.m., Mr. F. E. Eve, Some Points in Pathology.

ROYAL COLLEGE OF PHYSICIANS OF LONDON.—At 5 p.m., Croonian Lecture: Dr. Hughlings Jackson, Evolution and Dissolution of the Nervous System.

THURSDAY, MARCH 20TH.

ROYAL INSTITUTION.—At 3 p.m., Professor Tyndall, On the Older Electricity.

HARVEIAN SOCIETY.—At 8.30 p.m., Mr. Sewill, On a Case of Cataract and Spasm of the Facial Muscles due to Dental Irritation.—Mr. F. Treves, On certain forms of Intestinal Obstruction that may follow after hernia.

FRIDAY, MARCH 21ST.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—At 4 p.m., Mr. F. E. Eve, Some Points in Pathology.

ROYAL COLLEGE OF PHYSICIANS OF LONDON.—At 5 p.m., Croonian Lecture: Dr. Hughlings Jackson, Evolution and Dissolution of the Nervous System.

Vacancies.

Birmingham Children's Hospital.—Dispenser. Salary, £80. Applications to the Secretary by April 1.

Brighton Lying-in Institution.—House Surgeon. Salary, £120, with furnished apartments, &c. Applications to the Secretary before April 4.

Coombe Hospital, Dublin.—Assistant Master. Applications to Master, or at Coombe Hospital.

Flintshire Dispensary.—House Surgeon. Salary, £100, with furnished house, &c. Applications to the Secretary by April 15.

Kent Hospital.—Physician on the Staff. Applications to the Secretary at the Hospital, Canterbury, by March 22.

Appointments.

LUCA'S, A. M.R.C.S., Medical Officer for the Eighth District of the Newport Pagnell Union.

MACDONALD, W. C. M.B., C.M. Glas., Government Medical Officer at Ingham, Queensland.

MAYO, F. H. M.R.C.S., L.R.C.P., House Surgeon to the General Infirmary, Leeds.

NANCE, H. C. M.R.C.S., L.R.C.P., Senior Resident Medical Officer to the Hospital for Sick Children, Pendlebury, Manchester.

OLIPHANT, E. H. L. M.B., C.M. Ed., House Surgeon to the Glasgow Maternity Hospital.

PROWSE, K. L. M.B. Durh., L.F.P.S. Glas., Medical Officer for the Workhouse of the Sunderland Union.

RICHARDSON, H. E. L.R.C.P., L.R.C.S., Senior House Surgeon to the Borough Hospital, Birkenhead.

STACPOOL, A. R. L.R.C.P., L.R.C.S. Ed., Resident Medical Officer to the Sydney Hospital.

STEWART, C. W. M.D., Physician on the Staff of Anderson's College Dispensary, Glasgow.

WATT, T. M. L.K.Q.C.P.I., M.R.C.S., Medical Officer for the Hovingham District of the Malton Union.

WHITE, J. M. M.A., M.B. Edin., M.R.C.S., Medical Assistant to the Dundee Royal Infirmary.

WYER, O. F. M.D. Glas., Honorary Physician to the Warfield, Leamington, and South Warwickshire Hospital.

Births.

ATLWARD.—March 10, at Bramley Hill, Croydon, the wife of Ernest Aylward, L.R.C.P. and S. Ed., of a son.

BLATHERWICK.—March 12, at Dunsailon, Dumbartonshire, the wife of Charles Blatherwick, M.D., of a daughter.

COOMBS.—March 12, at Redburn, Bedford, the wife of Rowland E. Coombs, L.R.C.P., of a daughter.

CORBETT.—March 11, at 6 Crofton Terrace, Kingstown, the wife of D. Corbett, jun., F.R.C.S.I., of a daughter.

Marriages.

HARLEY-WHITNEY.—March 10, at Christ Church, Cork, Dr. E. W. Harley, of Dublin, to Harley, youngest daughter of the late Elliott Whitney, Esq., Woodlands, co. Wexford.

Deaths.

CORBOULD.—March 12, at Somers Road, Reigate, Francis John Corbould, M.D., aged 65.

DENTON.—March 9, at his residence, Ivy Lodge, Hornsea, Samuel Best Denton, M.D., F.R.M.C.S.L.

HOOD.—March 10, very suddenly, at the Château de l'Espagnerie, Pas de Calais, France, Thomas Hood, M.R.C.S. Eng., L.R.C.P. Ed.

LESLIE.—February 4, at the Battle of Tob, Surgeon-Major A. Leslie, son of the late David Leslie, M.D., of Leslie Hill, co. Armagh, and of Wandsworth, London, aged 38.

SHARMAN.—March 10, after a short illness, at his residence, Brimingham, Malim Sharmam, M.R.C.S., aged 59.

ULMIN.—March 13, at his residence, Upper Clapton, Francis T. Ulmin, F.R.C.S., aged 82.

WALSH.—March 7, at his residence, Balrath, co. Meath, James C. Walsh, Fleet Surgeon R. N., aged 64.

WATSON.—March 6, at Landsdown Crescent, Bath, Thomas Sander Watson, M.D., aged 83.

A Course of Lectures

Delivered at the London Hospital during February, 1884.

By JONATHAN HUTCHINSON, F.R.C.S., F.R.S.,

V.—ON SYPHILITIC LUPUS.

Emeritus Professor of Clinical Surgery at the London Hospital;
Consulting Surgeon to the London Hospital, and to the Royal
London Ophthalmic Hospital.

In discussing the question whether a distinct disease deserving the name of syphilitic lupus, could be said to exist, Mr. Hutchinson said it would be desirable to make some study of the ordinary form in which lupus presents itself, for although it is held by some persons that it is inconvenient to give the term to any kind of syphilitic eruption, still, in his opinion, it added greatly to simplification and convenience to assign such a term to several of the maladies arising in connection with syphilis, for the reason that they assumed appearances essentially the same as where no syphilitic complication entered into consideration.

Notwithstanding that the affection possesses very marked clinical features sufficient to enable its detection to be made an easy matter, still it does not always exhibit exactly the same characteristics, these varying within somewhat extended limits, and leading to conditions of diversity. The group of skin diseases, however, to which the name "lupus" could be properly applied, are found on the skin or mucous membrane, and progress but slowly. They commence as new growths of inflammatory tissue from which infection extends to contiguous structures, spreading by local infection from the edge and travelling to a distance from the original patch. The extension of the disease proceeds by a serpiginous path, and this, as well as its infective nature, must be borne in mind in examining with a view to its determination. The precise tissue which serves as the

site of the lupous growth has been made the subject of much inquiry, the result of which is to show the probability of its being found in some or any of the deeper layers of the cutis; and it has been asserted by microscopists that it always originates in a situation immediately around the glands which exist so plentifully in the skin. There is a considerable amount of probability that such an explanation approaches the truth, and that the lupous cells are first of all produced through a slight inflammation attacking the tissue circumjacent to these glands, or in the perivascular spaces of the sub-cuticular structures. In their earliest stages such cells are not unlike the ordinary granulation cells, and following their initial development they become thereafter slowly disseminated around. The first half dozen cells become potential agents for unlimited distribution of the disease by extension, so that as soon as one nodule has been formed it becomes the source of origin from which another nodule springs; and so on, from pre-existing collections of lupous cell growth, an almost unlimited multiplication of little masses of the foreign growth constituting it can become possible. It is thus, when once it has been formed in the skin, endowed with the power of perpetuating itself continually; and at the outset it does not demand any very strong cause to act as an exciting agent in its production. If, however, it be attacked at the commencement, and is carefully and completely removed, there is a good chance offered of preventing any further extension of the disease, especially as it is not marked by any strongly constitutional traits; although it cannot be affirmed that it is wholly unattended by constitutional tendency to its development in those individuals who are affected by it. It is, however, highly important to obtain a clear understanding of the causes which do excite to its production, and in this connection the predisposition offered by the tuberculous diathesis holds a very prominent place.

And here it is desirable to appreciate the fact that external agents are by no means essential to the production of tuberculosis in persons predisposed to the disease; but at the same time there is no question of the

great influence exerted in such cases by bacilli, to the development of which in tuberculous subjects the occurrence of a process of inflammation is an essential requisite. Lupous patients, moreover, are frequently found to be related to persons who are suffering from phthisis; or they may themselves be victims of consumption; or they may exhibit undeniable evidence of a scrofulous habit, by reason of their possessing tissues of a low order of organisation, and in which, when once they have become the seat of inflammation, the inflammatory process pursues a course that is manifestly of a more destructive quality than is witnessed in patients who do not inherit the strumous diathesis. Even then, however, in spite of their specific tendency to inflammations of the type described, and under certain circumstances, they become subjects of inflammatory changes that are altogether unattended with the production of any tubercular deposit whatever.

The important assertion having been made, and supported among others, by Sir Erasmus Wilson, that lupus is invariably syphilitic in origin, Mr. Hutchinson offers a denial to the position thus assumed, and does not believe that inherited syphilis is a predisposing cause in this respect. By patient examination of numbers of persons bearing unmistakable signs of hereditary syphilis, and by extending his observations also to inquiries embracing, when feasible, the whole family history of such cases, he has convinced himself that they do not show any tendency to lupus as a consequence of the specific taint. Nor among the same description of patients has he succeeded in discovering any examples of the ordinary form of lupus as being necessarily sequential to inheritance of syphilis. The same statements apply with equal force, also, to generations remoter than the first degree of descent, while there is at present no proof that syphilis is ever transmitted further than the third generation from that in which the primarily affected individual had a place.

Common lupus is a remarkably persistent disease, but nevertheless, it does not exhibit a tendency to indefinite spreading from a simple patch, but it possesses many points of resemblance to malignant affections, in the variations shown in respect to its continuance for long periods in an almost stationary condition. In one case observed, a lupous growth existed for upwards of twenty years on the face of a lady, and many examples have been collected illustrative of the same character of persistence. The case of this lady was further interesting from the fact that the same patient possessed a small cancer on the side of her nose, and from this, and other similar instances, the conclusion seems to be warranted that some sort of alliance between the two diseases, lupus and cancer is not improbable. Lupus, however, cannot be mistaken when once its distinguishing features have been thoroughly understood; it presents an abruptly circumscribed area of limitation, the growth having a semi-transparent appearance, and bearing a close resemblance to apple-jelly. The situations selected by the growth for its development are those parts of the body which offer themselves most readily to the influence of agencies whose effect is to undermine the vigour and promote degeneration of structure; and in this connection the nose is a very favourable part of the face, being easily chilled through exposure, and being at the same time plentifully supplied with those sebaceous tissues for the selection of which lupus has already been shown to have a partiality. The persons most frequently affected by this description of lupus are such as combine with brown coloured eyes a certain peculiar tint of complexion which is rarely dissociated from them, and the existence of which in these subjects of the disease is readily confirmed by inspection.

Another form of lupus exists in which innumerable patches of the characteristic apple-jelly growth will be found scattered over a considerable area of skin, and presenting an appearance almost resembling that given by psoriasis. In this class of cases it was thought that a constitutional factor was at work, to which the multiplicity

of the growth could be attributed; and from the characters by which it was recognised Mr. Hutchinson formerly assigned it the name lupus psoriasis. The multiplicity, however, is of a non-symmetrical type, which it would not be if it were true that it rose from constitutional causes, and the inference is, therefore, unavoidable, that the condition is produced by a process of infection spreading from the parent patch in the first instance. But this explanation does not preclude the acceptance of a belief that, in some cases, a truly constitutional cause exists, and that, as a result of it, a form of multiplied lupus will be exhibited in which the symmetry will be perceptible.

Changes, due to setting up of inflammatory processes, may not act as complicating agents during the growth of lupus; but when these do occur, the most distressing deformities may be produced in consequence. For the double purpose of illustrating this fact, and at the same time cautioning his hearers against a not uncommon error of ascribing all cases of perforation of the septum nasi and hard palate to a syphilitic origin, Mr. Hutchinson mentioned a case recently under his care. It was that of a young lady in whom an attack of lupus had invaded the skin of the face, and whose sister had two years previously suffered from a small sore situated on the septum nasi, and which was what not at once thought to be of the nature of lupus. It progressed to perforation, and the subsequent history of the case, with that also of the sister, left no doubt remaining as to the really lupous character of the growth from the first.

A form of lupus not unlike acne in its appearance is sometimes seen, in which numerous patches of destructive apple-jelly-like tissue are developed, and which may be at once distinguished from acne by the absence of any tendency to healing on the part of the little pustules following the discharge of their contents, a condition which does not obtain in acne proper.

It has already been mentioned that some sort of association seems to be discernible between lupus and cancer, and in this connection cases are met with in which patients who seek relief on account of lupus, and who undergo treatment resulting in the cure of that disease, will subsequently return to the care of the surgeon with cancer developed in place of reproduction of the lupus.

Lupus erythematosus is a form of the disease which is very different to the common kind; but intervening varieties exist in too great number, and exhibiting too finely marked gradations to admit of any doubt respecting the close alliance of the two forms. The main distinction separating them is found in the constitutional causes originating the lupus erythematosus, which form the commencement is a symmetrically distributed affection, whereas lupus vulgaris is never symmetrical in development from the beginning; from which the conclusion is justified that it owes its origin to local influences. Lupus erythematosus may be regarded in the light of a disease produced as the result of an exaggerated chilblain diathesis on the part of those in whom it is found; and it presents itself in persons who are either subject to chilblains themselves, or are directly related to others who exhibit a tendency in this direction. From time to time a large number of varieties of lupus coming under the category of lupus erythematosus have been recognised, but a good many of them are only of rare occurrence. In some cases the disease assumes the hæmorrhagic type; in others gradations between it and lupus vulgaris and ordinary chilblains may be observed, but the situations selected for its development are those parts of the body subject to exposure.

From the foregoing descriptions of the various recognised forms of lupus it is easy to comprehend under what a multitude of shapes it may present itself, and to understand the necessity there is for a liberal definition of the single generic term under which they are grouped, and which includes all those tardily advancing diseases which disorganise the skin of the region in which they are developed, which grow in a serpiginous direction, and which

leave a scar behind to mark the position of their occurrence.

Under the term "syphilitic" it is possible to group certain forms of lupus which occur in subjects of the syphilitic diathesis, whether it be acquired or inherited; and although the particular inflammatory changes in the skin of such persons may assume the most different appearances, still they all agree in exhibiting serpiginous mode of growth, of an infective and disorganising character, and leaving a scar in the skin. Under the circumstances associated with their development in syphilitic individuals these forms of lupus require to be specified as syphilitic varieties, but save for the unlikeness of the cause which originates them they all agree with lupus vulgaris in essential points. This cause in the former class of cases is usually the receipt of a slight injury acting on a part already under the influence of constitutional specific infection. In these, the term syphilitic lupus is more than justified from the difficulty attending determination of the exact nosological relationship of the disease, whether, that is, it ought to be relegated to the class of affections called lupous, or to that known as syphilitic.

The clinical varieties of syphilitic lupus include several forms, among which the "horse-shoe patch" is well marked. This is a slowly creeping, serpiginous sore, which is rarely seen in a complete state, and by the character of which in this respect it may be differentiated from lupus vulgaris. In the latter, the edge of the patch is generally continuous, whereas in the syphilitic variety a gap is usually observed in some portion of the periphery of the sore. The tendency to formation of pus, also, is distinctly less marked in some forms of syphilitic as composed with common lupus; and in other cases a tuberculous lupus may persist in syphilitic patients without undergoing any considerable extension for possibly as long as twenty years. The specific nature of these forms of the disease can, however, be at once demonstrated by watching the influence exerted over them by the administration of iodide of potassium.

In some cases the disease may have the appearance only of an extremely superficial erythema; but its subsidence will in such instances also be followed by the production of a scarring, though of a slight degree.

In the secondary stage of syphilis the mucous membrane is a common seat of infective patches of lupus, and in such cases the disease assumes a more aggressive form than when uncomplicated by syphilis, though occurring in similar situations. Any portion of the mucous membrane of the body may become thus affected, *e.g.*, mouth, vagina, rectum, nose, tongue, &c.

Treatment directed to the cure of lupus, whatever may be the particular plan pursued, always aims at (1) removal of the cell-growth, and (2) eradication of the source of infection; and whether the origin of the disease be ascribed to syphilis or not, the same general plan is invariably pursued, and is equally effectual as regards local treatment, although it is modified by the difference introduced by constitutional infection.

In this connection Mr. Hutchinson impressed upon his hearers the importance of not placing implicit reliance on the powers of cure residing in any single drug, however vaunted its efficacy might be, and narrated the following case as an instructive example to enforce his suggestions. A year ago, a man, *æt.* 30, was admitted to the London Hospital, having been discharged from a special skin hospital as being incurable. His whole body was spotted with huge patches of syphilitic lupus, and had been so for years. Iodide of potassium had been given to him continuously for a long period, and latterly in enormous doses, but without effect, and the disease showed no signs of giving way to the treatment, although, as well as internally, the drug had been administered externally in the form of ointment. After some time the patient was put under the influence of mercury, to salivation, and almost immediately a change for the better ensued, and

ere very long every patch of the lupus disappeared, and the man went away quite well. Hence it is clear that some cases of tertiary syphilitic lupus receive most benefit from a mercurial treatment, while others respond most readily to iodide of potassium, and no case ought to be regarded as having been fairly dealt with until both these remedies, separately and combined, have been employed without producing relief to symptoms. In addition, also, it must not be forgotten that local measures are demanded in both syphilitic and common lupus, the object being to eradicate the cell-growth distinctive of the disease in either case. For this purpose acid nitrate of mercury, or other efficient caustic must be used, and thorough removal of every trace of the infective point be carefully ensured before it can be fairly considered that all has been done that the circumstances require. Early adoption of these measures will suffice to oppose the progress of even the most destructive forms of lupus, those occurring in subjects of inherited syphilis, but success can only be obtained by means of resort to radical modes of treatment, designed with a view to local removal of the disease.

In conclusion, Mr. Hutchinson hinted at the possibility that organs of the body hidden from view might, like surface parts, become the seat of infective lupous patches, evidence of their existence being found in slowly advancing injuries to nerves. The tendency of such processes to spread could be arrested by anti-syphilitic remedies.

The Gulstonian Lectures

ON

NEUROSES OF THE VISCERA.

*Delivered at the Royal College of Physicians, London,
March 7th, 12th, and 14th.*

By T. CLIFFORD ALLBUTT, M.A., M.D. Cantab., F.R.S.,
F.R.C.P. Lond.,

Senior Physician to the Leeds General Infirmary; Consulting Physician
to the Leeds Hospital for Women and to the Fever Hospital.

LECTURE II.

MR. PRESIDENT AND GENTLEMEN,—We all know the story of the resentful lion who had so often been painted by the man, and who longed for the time to come when the man in his turn should be painted by the lion. Is it because all medical books have been written by men that gastralgia, one of the sharpest arrows in the armoury of pain, is in many of them dismissed with a few words as a malady of "hysterical women," of women, that is, whose sufferings are due in part to effeminate habits and constitution, and in part to a kind of fanaticism which prompts them to cherish or to imagine pain, or to make a bitter cry about small matters.

We all ought to know that gastralgia is common enough in man also, though certain writers appear to deny that this or any other visceral neurosis can exist where no uterus is; and in my first lecture I have endeavoured to formulate a distinction between what I may call the upper class of neurotics and their degenerate relations the hysterics; asserting therein that, in hysterics, pain is not a more, but a less common inheritance, and that to neurotics it is chiefly given to suffer pains and the renewal of pain, and to bear all with singular fortitude and spirit. As such a zealous neurotic the Sompnoure posed when he described himself thus:

"I am a man of litle sustenance,
My spirit hath his fostering in the Bible,
My body is ay so redy and so penible
To waken, that my stomak is destroyed."

For of all the neuroses of the stomach gastralgia is the chief; but around it gather, in more or less close association, flatulence, vomiting, hyperæsthesia, and miseries

such as distension, sinkings, cravings, or loathings of food, and these may exist in various associations, or may exist singly.

As in angina pectoris and the pseudo-angina, so in gastralgia, the spinal nerves may be included in the paroxysms, or may take even a chief part in them, the visceral and overlying spinal nerves being grouped in function and in suffering together. In order to study this class of cases more carefully, I have gone over the case-books of my chamber-consultations for ten years past, namely, from the year 1874 to the year 1883 inclusive. From them I have extracted 139 cases of gastric and abdominal neuralgias. These cases remain after eliminating all that are doubtful or comparatively trivial in degree; all cases attended with important uterine disorder, or complicated with substantial defect in any organ whatsoever, or with disease; all hysterical cases, and all cases of fretful or whimsical persons prone to expand or to exaggerate their symptoms.

The selected cases, then, are the cases of persons of whom I have some tolerable notes, who were straightforward and truthful, and who are, or were, the subjects of neurotic or neuralgic affections lying under the diaphragm and above the pelvis. Now, the great majority of these cases are gastralgias, the region of the stomach being by very far the commonest seat of abdominal neuralgia. Of the gastralgics the majority are women, in the ratio of two to one. In men and women gastralgia is by no means confined to middle life, as Leared supposed, but is found at all ages, from 14 to 60, being most common between 20 and 45. Like migraine, it tends to die out in middle life, and, like migraine again, it is attended less and less with vomiting as age increases. Gastralgia comes on earlier in woman than man, apparently by some ten years. A gastralgic man is rare before the twenties; girls often begin in their teens.

The earlier maturity of the girl sufficiently explains this difference, which is also remarkable, though I think in less degree, in migraine. Migraine may, however, begin at very early ages in either sex. Of associated affections migraine is by far the commonest; and, if we associate migraine and neuralgia of the head and face together, the number of cases in which these are found with gastralgia is very great, seeming to be fully 80 per cent. Fortunately, these affections do not often coincide in time, but rather alternate variably one with the other. A large number of gastralgics, then, include migraine or neuralgia of the head and face in their life-histories. Another disorder commonly associated with gastralgia is asthma, an observation which scarcely needs either explanation or much asseveration. Neurotic vomiting may accompany, or rather alternate, with asthma, as the gastralgia may; and so again may voluminous flatulence, borborygmi, and other such neuroses. Like asthma, gastralgia is not unfrequently nocturnal in its recurrence, and is likewise often aroused by improper food, or by the contact of any food whatever. Hence the persistent confusion of gastralgia with dyspepsia. Asthma and gastric neuroses, moreover, if not concurrent in the individual, are often concurrent in families, one member suffering from the latter, and his brother, sister, or other relative from the former. With both these vagus neuroses run the cardiac neuroses, including true angina. I am now attending a gentleman with Mr. Jessop, who suffered terribly from paroxysmal gastralgia in past years, and in whom we have now to deal with the true angina. In gastralgics occur violent attacks of palpitation, or, more characteristically, attacks of slow or intermittent pulse, as in the following case:—

Mrs. —, æt. 24 (No. 371, 1875), suffers from marked gastralgia. She has one child, which she is nursing. She consults me now for pain in the region of the heart of a dull prolonged kind, ending in a sense of exhaustion. The pain may strike to the back and under the left shoulder-blade. At such times the heart becomes very slow (48 to 50), intermittent, and irregular. Curiously enough, such attacks are brought on at once by putting

the child to the breast, even before much milk is withdrawn. This sequence is analogous with the sequence of gastralgia after the ingestion of food, the neuralgia being awakened by a peripheral irritant. She soon recovered on appropriate treatment; but, in 1881, after some menorrhagia, the same thing recurred. She again recovered on like treatment. She had had one child between these dates without any disorder of health.

In No. 371 appeared moderately a radiation of pain upon the spinal nerves; this, in other cases, may extend or intensify itself to a degree of pseudo-angina which may even be indistinguishable from real angina.

No. 283, 1878; male, æt. 37. Of nervous temperament and a zealous worker; is liable more frequently to violent gastralgia, especially after worry and excitement. Less frequently, he has "heart-spasms." In these he has a sense of swelling at the heart, and pain and numbness down the left arm. At the same time, the pulse becomes "much enfeebled," and is said to be slowed down as low as 20 in the minute, or may even become imperceptible (this from his own doctor). These attacks have come occasionally for many years. Physical exertion does not call them forth. All organic factors seemed normal.

Cases like these may be culled from every year's entries. In one lady, æt. 33 (No. 261, 1881), wholly free from menorrhagia or leucorrhœa, an intense aching, with a sense of extreme exhaustion and sinking, would come on at the heart; it recurred then daily, and it was always periodic, appearing about 4 or 5 p.m. She was compelled at such time to lie down and "press the heart," turning over on the left side towards the prone position. These attacks were encouraged especially by any abbreviation of sleep or by fatigue. She herself is subject to gastralgia without dyspepsia, and her mother was mildly epileptic.

Dr. Ramsay, of York, has often consulted me concerning Mrs. —, æt. 43, who more than once, with miscarriage, had lost blood heavily. She is very subject also to menorrhagia, which is scarcely kept in check by close attention to local and general remedies. She is, however, wholly free from any persistent affection of the womb or of other organs. She suffers occasionally from gastralgia, but her great distress consists in attacks of stabbing pain, as if the apex of the heart were pierced by an arrow; the pain then extends with intense cardiac oppression down the left arm to the fingers, causing a numbness there. The pulse falls from an average of 70 to 60, but is not otherwise much embarrassed. She has the faintness and dread, and, in a word, her symptoms are not in themselves to be distinguished from angina pectoris.

The same difficulty of immediate diagnosis is found in the very similar case of Mrs. —, a patient of Mr. Lee, of Dewsbury. In her, also, is a persistent disposition to menorrhagia, and also to utero-vaginal catarrh. In these and like cases diagnosis depends less upon the character of the attacks themselves, and more upon the other records. The attacks are commonly due to such losses as menorrhagia or severe leucorrhœa, or to prolonged mental distress; they are not directly produced by bodily exertion, but are often caused indirectly by the resulting fatigue. In some of my cases, again, the pains are more extensive than is usual in angina. In some the pain runs down both arms alike, or runs down both arm and leg of the left side, or again springs upwards from the cervical plexus to the same side of the face and head. Valleix points may be detected in the course of the spinal nerves, but in many cases of pseudo-angina they are not definitely to be distinguished. In women we may rely on the lesser frequency of true angina in them, though the pseudo-angina is often met with in men. About 20 per cent. of my cases of pseudo-angina were in men. In one gentleman, of neurotic habit and ancestry and whose family-affairs were laden with sorrow, such attacks occurred, involving seriously the action of the heart itself, and producing the dread, the ashen countenance, and other marked signs of true angina. As his luck in many ways turned for the better, his attacks diminished, and I believe he has

now been free from them for nearly ten years. A favourable opinion in his case was founded upon his age (30 to 36), his diathesis, his unhappy circumstances and his organic soundness. The tendency in all these cases to retardation of the pulse brings them, apparently, into the group of vagus neuroses, with asthma and gastralgia; nor will intercostal and cervico-brachial neuralgias cover all their phenomena, such as the dread, the pulse-changes, and (2) the peculiar pains which patients refer instinctively to the heart (as in Case 261, 1881, *supr. cit.*).

It is perhaps impossible duly to attribute to each nerve or system of nerves its own share in these phenomena; even the essay by Professor Eulenberg seems to me to leave the matter pretty much as any intelligent observer may well have guessed it for himself. Still I think it seems clear that the phenomena of pain and spasm are probably due to the pneumogastric nerve and the intercostal and spinal nerves associated with it, while such other sufferings as faintness, sinkings, cravings, distensions, palpitations, abdominal pulsations, flatulence, retching and vomiting, pyrosis, diarrhoea, lithic or watery urine, insomnia, and so forth, may be attributed to the sympathetic alliances. Pulsations of the abdominal aorta in neurotics, whether men or women, may be so definite, may simulate aneurism so closely, and do so often appear after some history of effort or strain, that diagnosis upon direct observation may be as difficult as in the case of pseudo-angina, and may as therein derive most of its force from the history of the patient and of the family disposition. Avoiding digression, however, and returning to the association of pain in the spinal nerves with pain in the viscera, we observe that cervico-brachial and intercostal pains are found with gastralgia as well as with the pseudo-angina. Out of many cases of the kind I may refer to Miss —, (No. 504, 1883), who suffers from gastralgia of the ordinary type, but severely. The attacks are nocturnal. The pain runs down the left arm, until the arm feels quite benumbed and useless. She has faint feelings, but no anginiform distress, her catamenia are regular and normal, and she has no leucorrhœa. Her family history is very neuralgic. She bore arsenic badly, but was quite cured by a careful use of it.

Mrs. —, æt. 30 (No. 403, 1881), had visceral neuralgia ten years ago, and now for two years past, she has ordinary epigastric gastralgia, unconnected with digestion; and her attacks are usually nocturnal. The pain runs into the left submammary and axillary regions, and into the arm. At other times, she had suffered from recurrent enteralgia, similar in character to the former, but then running down into the groin. Her uterus and ovaries are normal, and her catamenia regular. She has no leucorrhœa. At the beginning of her attacks, she passes urine frequently—say six times in an hour; then, as the attack subsides, the bladder likewise goes to rest. She came to me on account of frontal and parietal cephalalgia of fourteen days' duration, during which time she had had no visceral pain.

Mrs. — (No. 38, 1877), æt. 30, has had migraine and cephalalgia for years. Her sister is a pronounced gastralgic. For two years she has been subject to attacks, "pinning the shoulders tight," and girding her with pain round the waist. The pain almost stops the breathing, and so continues for two hours. She then vomits, and the pain departs. She never had jaundice. She looks worn out with pain, but all the organs and functions seem normal.

Mr. —, a cashier (No. 86, 1876), æt. 28, had pains as in the preceding case; they were periodical in recurrence. But in his case the attacks culminated not in vomiting, but in diarrhoea. He recovered completely on tonics, with rest and change of air. He had a neurotic history, personal and inherited.

Miss —, æt. 30 (No. 51, 1876), presented symptoms almost identical with those of No. 38, 1877, including the critical vomiting. She was also subject to morning vomiting, attended by frequent micturition. She used to have headache with the vomiting, but not for some

time past, though she has severe temporal neuralgia occasionally.

Another very curious symptom which occasionally occurs with gastralgia is yawning. I have seen this more than once, and may quote P. T. P., a grocer, æt. 33 (No. 571, 1882), who suffered from gastralgia in the usual way, but with an incessant and irresistible tendency to yawn.

Vomiting is a symptom which, in some cases of gastralgia, takes a very prominent place, but in others is never seen. I have already drawn a parallel between the vomiting of cephalalgia and the vomiting of gastralgia. In either case, the vomiting may stand alone—may stand without headache, or, again, without stomachache. In such cases, it may only be known from the case-history whether the vomiting belong to the one order of things or to the other; but the vomiting allied to migraine is more commonly in the morning, is more periodic, and recurs at longer intervals; the vomiting allied to gastralgia is more dependent upon the ingestion of food, is irregular in recurrence, and may, indeed, be daily or incessant. As an example of the former, of migraine without headache, that is, let us take the following case.

Miss —, æt. 27 (No. 14, 1880), comes of a neurotic family, and she herself had had migraine for nine years. Then the headaches gradually wore off, the vomiting attacks only remaining. These were not very violent, but returned at short intervals. They would last for about two days, during which time she had to keep as quiet as if she had a sick headache. Mental work or excitement most readily recalled the attacks. Her uterine functions and those of the digestion and bowels were all normal. This patient was a lady of attractions both personal and mental, and her case presented many interesting features. Her vivid perceptions, alertness, incessant and beneficent activity, and utter unselfishness, marked her as a type of the more highly endowed neurotic, and I took much interest in her case. A good deal of amendment was obtained by pointing out to her the truest economy of strength and work, and by insisting upon complete rest at times of malaise.

Mrs. — (No. 22, 1880), presented similar symptoms. She used to have full migraine; but from it the headache gradually disappeared, and left only intense and prostrating vomiting, which would recur much as the full migraine used to do, and would last, like it, for five or six hours and then vanish away. In her no functional derangement was present, and she derived great benefit from a mixture of bromides and hypophosphites. The same combination was also very valuable in the preceding case (No. 14).

In such cases, the vomiting, though a visceral neurosis would seem to be of cerebral origin.

Let us now turn to cases in which vomiting seems to be a limb or remnant of gastralgia. The first is such a complex case as we might well expect to find. No. 44, 1875, male, æt. 59, for "all his life," has been liable to sick-headaches. But these would often alternate with gastralgic attacks, which were also attended with vomitings. He is of very nervous temperament, has many cares, and no holidays. Facial neuralgia is a common ailment in him; but, for two years past, his trouble has mainly been vomiting in a morning, a little phlegm only being ejected. Day after day he finds himself unable to retain food until dinner time. Now, this seems to have been gastralgic vomiting; and he was cured by a course of bromide of ammonium, with hydrocyanic acid, followed by a course of Easton's syrup, with much general good advice. Two years later, he had had no return of the vomiting, nor of the gastralgia. I should add that he was a total abstainer of seventeen years' standing, and is so still. Now, it is somewhat remarkable that, although vomiting is common in gastralgia, and is common, also, in migraine, and although migraine and gastralgia may commonly rise in the same patient,

yet migraine and gastralgia seldom or never occur together. I suspect, therefore, that the vomiting of migraine is not identical in mode with that of gastralgia.

Although, as I have said before, vomiting is sometimes a climax-symptom in gastralgia as in migraine, yet in the former case it is perhaps reflex; in the latter it is perhaps allied to the vomiting of encephalic tumour or of concussion. Take, again, for instance, No. 25, 1878, male, æt. 23. At times of a morning he awakes in low spirits, and feels apprehensive and miserable. His appetite has vanished, nausea comes on, he vomits, and, after free vomiting of nothing, is all right. Now, this young man was quite cured by guarana. I have no history of frank migraine in him, but, like the former cases, I believe it to be migraine *sine cephalalgia*.

But Mrs. —, æt. 35 (No. 128, 1878), carries us, on the other hand, towards the stomach. She has leucorrhœa, a soft uterus, and flabby muscles everywhere, her heart-sounds being short and weak. She has no uterine catarrh. Her catamenia are disposed to anticipate, without being any the less in quantity. She is subject at times to intense neuralgia, at the supraorbital notches and in the orbits "poking her eyes out." Now every morning before rising she has nausea, which proceeds to vomiting. This is especially worse when she is much below par. There is also a great expulsion of inoffensive wind, and clear water runs from her mouth. At the same time, there is pain between the shoulders. Her appetite is never good. She is very temperate in the use of alcohol. The family history is phthisical.

Here we clearly have to do with the stomach, and I regard pyrosis as being for the most part a pure neurosis, probably vaso-motor; for the following case of Mrs. —, æt. 41 (No. 503, 1881), takes us a step farther. Seventeen years ago she fell ill, as at present, but, on the whole, she had enjoyed fair health in the interval. Her attacks are as follows:—A sensation of languor and exhaustion is followed by intense pain at the stomach, and vomiting soon sets in. She heaves up clear water, and clear water only. If food comes it is by chance, for the attacks have no connection with diet nor with meal times. The attacks may recur even as often as three or four times in twenty-four hours, and with them she has also a pain in the back, "screwing her to death." But not unfrequently she has the vomiting and ejection of water only, unattended then with either pain. She never has any nausea. Her uterine and other functions are normal, and the attacks do not favour the catamenial periods. All commemorative facts, personal or relating to family, have a neurotic quality. This lady recovered her health at the time under the use of arsenic and like remedies, and remained well until a little while ago, when she called upon me, complaining of some return of the vomiting, but without any gastralgia. The stomach-ache, she said, "used to be terrible."

Here, then, we have in close association, and evidently of one nature, gastralgia, vomiting, and pyrosis or the ejection of water. In the similar case which preceded it we had the ejection of volumes of wind also. This, I say, would lead us to believe that pyrosis, for the most part, is a gastric neurosis; and if we are then led to inquire into the personal and family history of the subjects of pyrosis, we shall find that, as a general rule, these persons present evidence of belonging to the neurotic class. Indeed, the regurgitation of food itself is by no means always due to (3) error of digestion; it occurs in many neurotic persons as a purely reflex neurosis during normal digestion.

Henry B., æt. 25 (No. 631, 1881), tells me that for some time he had been unable to prevent the regurgitation of food after all his meals, which is very annoying and unpleasant to him. He is not conscious of any dyspepsia whatever, nor can I find any evidence of it. His tongue is clean, his bowels are regular, and his urine of normal quality. He called upon me because of a severe attack of neuralgia in the infra-orbital and

dental branches of the right side of the face. No local source of irritation could be found. The remarkable thing is that on that day and thenceforth the regurgitation wholly ceased, and under the use of quinine the facial pain ceased also. He had no return of either disorder during my observation of him.

The grocer, P. T. P. (No. 571, 1882), who yawned so much, had also this vexatious regurgitation of mouthfuls of food after his meals. The symptom is doubtless due to an irritability of the muscular walls of the stomach setting up an excessive, and it may be an inverse, contraction of the viscus under the stimulus of digestion, and is a phenomenon of the same order as painful hyperæsthesia of the inner surface of the organ, of which I shall have to speak at length. Before passing to that symptom, however, I must leave regurgitation to consider another form of vomiting—vomiting, that is, not on the empty stomach, but on the full stomach.

This terrible malady is described commonly enough, yet it seems to me that it is but ill discriminated, being mixed up with hysterical vomiting on the one hand, or handed over to the gynaecologists on the other. Uterine vomiting, on the one side of it, is to be known by due investigation of the case, and is curable by uterine medicine or surgery. Hysterical vomiting, on the other side of it, is not so easy to separate from the malady I have in hand, unless there be, as for the most part there is, the broad difference that hysterical emesis is consistent with fatness, gastralgic emesis never is, but leads straitly to emaciation. In many cases, the vomiting is preceded by pain, more or less severe, and in these ulcer is often suspected, but in others there is no pain whatever. In both cases—in the case of those with pain and those without—the cause is cognate, if not identical. Let me instance a case from Dr. Salter's work on "Asthma" (ed. 1868, p. 256)—one adduced by him as an instance of "perverted innervation of the pneumogastric nerve." Condensed to the utmost, the story is this—

A little girl, æt. 8, rejected food of any kind the moment it was swallowed. There was no pain, no tenderness, no feeling of sickness at any other time. After vomiting had emptied the stomach, she would be quite well. The same thing occurred with any little matter, such as blackberries, that she might eat between meals. She fell into weakness and emaciation; all remedies being useless. Some years afterwards, Dr. Salter made inquiries about her, and found that the vomiting had been supplanted by spasmodic asthma. The two maladies had, indeed, alternated with each other at times, the vomiting coming on when the asthma was better.

It is enough to make one's blood boil to hear of a poor girl, wasted to a shadow by such a distress, treated, almost with gibes, as hysterical, when she is the subject of a malady as real as the doctor's own toothache, which, in its turn, might vanish by the way the moment he should find himself on the dentist's doorstep. I have a case in my mind which was recorded as hysteria by the late Mr. Skey, in the *Medical Times and Gazette*, 1866, vol. ii. (a) In this case, intense suffering followed the ingestion of food. The poor girl had foolishly yielded to the dread of food, and was in a pitiable state of starvation and distress; and yet, because Mr. Skey succeeded, as an entire stranger might well do, in diverting the sufferer by bright conversation on pleasant subjects, he neatly labels her as hysterical. I shall return to these cases presently. Hysteria may simulate gastralgic vomiting, as it may simulate asthma; but we should do ill, for that reason, to treat all asthmatic girls as hysterical, because their dyspnoea is neurotic. Happily, these cases of obstinate gastralgic vomiting, for so I will call them, are not very common, if we carefully separate them from hysterical imitations

a) For this reference and much help of the kind I am indebted to the invaluable labours of Dr. Neale, the compiler of the "Digest."

of them, from gastric catarrh, from alcoholism, from uterine vomitings, and so forth. Still there are too many of them, small as the class may be, and we may properly call the malady gastralgic vomiting, seeing that the mode of them is the same as of the cases wherein pain is also a factor. In some gastralgics, for instance, the two symptoms are not synchronous—the vomiting and the gastralgia replacing each other, as the vomiting and the asthma replaced each other in Dr. Salter's case above cited; or the vomiting may occur at one hour or under one set of circumstances, and the pain at another time and under other circumstances. For instance, in one of my patients, painless vomiting followed the meals, and soon gastralgia of the ordinary type came on in nocturnal seizures, after the manner of its cousin asthma. I find another case, under No. 112, 1881. Miss —, æt. 20. At sixteen years of age, she was subject to facial neuralgia, then to pain in the left chest and down the left arm. This left her in eight weeks, and she remained well for some months. Then gastralgia appeared. At first, this arose immediately on eating, or within ten or fifteen minutes thereafter. Then this pain vanished, and she became subject to gastralgia on the empty stomach only. This, in its turn, disappeared, and vomiting set in. The vomiting had gained upon her, and now she vomits all her food. It comes up in a mass, as eaten. She never brought up blood nor mucus. She is emaciated, but all functions and organs seem normal. There is no evidence of hysteria. She made a good recovery on arsenic.

(To be continued.)

Lectures

ON

THE EYE: ITS DISEASES, AND THEIR REMEDIES.

Being an Abstract of a Course delivered in the Royal College of Surgeons in Ireland.

By ARCHIBALD H. JACOB, M.D. Dub., F.R.C.S.I.,
Professor of Ophthalmic and Aural Surgery in the College;
Ophthalmic Surgeon to the House of Industry Hospitals.

(Continued from page 225).

SUPPURATION within the corneal structure is a common effect of acute circumscribed inflammation, and of injuries; it may also take place from simple inanition as a sequela of fevers, and I have seen it occasionally in children ensuing idiopathically from malnutrition and improper dietary. It is usually attended with severe lancinating circumorbital pain, but may, if arising from malnutrition, involve and destroy the entire cornea with very little suffering to the patient. The usual course is the formation of a minute centre of suppuration in connection with a herpetic nodule or a local injury, and the extension of that centre to a greater or less extent; the deposit of pus is shaded off into the outlying healthy cornea by a muddy areola which either breaks down into suppuration or becomes resolved and clears up. Sometimes the pus is from the first of the usual creamy yellow character, and may be drawn off by tapping the abscess, but more frequently at first it is of a cheesy white colour, sometimes closely resembling tuberculous deposit, and so infiltrated within the layers of the cornea that it cannot be removed by incision. These latter forms of suppuration are slower, more likely to spread, and more destructive of the corneal tissue, and they represent the formation of a quantity of fatty detritus within the corneal structure which eventually disintegrates the structure itself, and, breaking down into pus, makes exit either in front of the cornea, or into the anterior chamber. This disintegration without immediate formation of fluid

pus is what takes place when the entire cornea is engaged, as after injuries or operations, and in these cases the infiltration raises the diseased corneal surface above the general level, but the corneal layers still remain, to a certain extent uninjured, and the infiltrated matter is therefore not immediately cast off even when the surface is ulcerated, but gradually breaks down until the whole cornea is lost. Centres of suppuration may occur in any part of the cornea, but the weight of the infiltrated matter has a tendency to burrow downward and to extend the abscess in that direction; if the suppuration be limited in extent, occurring from a pustule or an injury in an other wise healthy subject, it may resolve, become absorbed, and the cornea may clear up, leaving no trace of the diseased condition, but more usually it makes its way to either the front or back surface of the cornea with results which will be described when I come to speak of the sequelæ of corneal suppuration and ulceration. When an abscess breaks into the anterior chamber the pus falls by gravity to the lower part, and filling up the angle between cornea and iris it presents from the front the appearance of a yellow crescent. Any effusion of pus into the anterior chamber is called *hypopion*, and also

from its resemblance in shape to the *lunula* of the nail, it received the name of *onyx*, but of late years this latter has been commonly used to indicate an intra-corneal patch of suppuration, while the name *hypopion* is employed to indicate the crescentic effusion into the anterior chamber, as shown in illustration.

The annexed illustration gives in profile the various forms of corneal abscess: The interstitial abscess suppuration, *e*, in which the broken down fat cells are distributed between the corneal layers. The *onyx*, *a*, *b*, *c*, in which the suppurating points are joined into an intercommunicating abscess. The *hypopion*, *d*, in which the pus has escaped into, or been deposited in, the anterior chamber. *Hypopion* may occur from discharge of abscesses which have their seat elsewhere than in the cornea, as, for instance, those

Fig. 19.

Corneal Abscess—*Onyx* and *Hypopion* (STELLWAG).

which occur on the iris in syphilitic iritis, or even in any suppurative disease behind the iris.

Treatment of Corneal Abscess—If a corneal abscess cannot be prevented from bursting, it will produce one of two permanent injuries—an opacity of the cornea or a displacement of iris and other parts behind the cornea. Therefore every effort must be made to obtain resorption of the effused matter, to limit the extension of the abscess, and, if it be impossible to do this, to allow the pus to escape in as harmless a way as possible by tapping the abscess near the corneal margin, where an opacity will do least harm. To obtain resorption the course to be adopted must depend on the urgency of the inflammatory symptoms: if these be violent, and if there be much pain, vascularity, chemosis of lids, and tension of eyeball, the first thing to do is to reduce the inflammatory condition by hot stupes, immediate but transient purgation, antimonial depressants, restricted dietary, and, if necessary, leeches to the temple, with the application of atropine drops once, twice, or thrice daily. To allay the severe pain it may be necessary to give hypodermic morphia injections beneath the skin of the temple, and, if the disease be in the initial stage, before pus has actually formed, the sulphide of calcium granules already referred to may be administered. This treatment is, however, only suitable for the earlier and acute stage, and should be kept within limits and

discontinued as soon as the inflammation is got under. When the acute symptoms are mitigated, the line of treatment should be directed to obtain resorption. The stupes should be discontinued and a compress bandage applied, the dietary improved, and tonics with iodide of potassium administered. Meanwhile the abscess must be watched, in order that it may be tapped if there should be danger of its breaking. This operation is done, as here illustrated, by a simple puncture with a lance-shaped knife, the opening being made as close to the corneal margin as will allow of the escape of matter. The incision should, of

Fig. 20. Tapping of Corneal Abscess, Hypopion (STELLWAG).

course, be confined to the abscess, and should not open the anterior chamber unless there be hypopion; nor should any attempt to tap the abscess be made if there is reason to suppose that the pus is infiltrated between the corneal layers and not free. In such cases the incision does not relieve the tension, while it increases the irritation.

If, notwithstanding every effort to obtain resorption, the abscess bursts on the corneal surface, it cannot fail to leave behind it an ulcer and consequent opaque cicatrix of greater or less extent, possibly only a minute cloud of the cornea, possibly a complete destruction of the entire substance and the substitution for it of a thin layer of cicatricial tissue.

Ulcerations of the Cornea belong, pathologically, to suppurative keratitis, but practically their nature and treatment have nothing in common with the suppurative disease just described. Corneal ulcers are the most common of all eye diseases, being liable to arise as the sequelæ of all corneal and many conjunctival diseases, and from superficial injuries of all sorts.

The chief purposes of treatment of all corneal ulcers is to prevent their extension—to limit the size and thickness of the cicatrices which they leave behind them, and to prevent them from perforating the cornea. These indications are fulfilled by removing any mechanical irritation to which they may be subjected, by allaying the inflammation if they be of the inflammatory, irritable type, and by stimulating them to heal if they are of the indolent type.

The mechanical irritant which is the usual cause of ulceration, and which prevents healing, is granular conjunctiva, and that disease in its full development is almost always accompanied with corneal ulceration which readily heals concurrently with the removal of the granulations, no special treatment of the ulceration being necessary or effectual as long as the granulations remain.

Corneal ulcers may be divided into—*a*, Irritable and inflammatory; and *b*, Chronic indolent, or asthenic.

The irritable ulcer is, generally, the outcome of a corneal herpes, and its nature and treatment are described in connection with that disease; but there are cases of

irritable, spreading ulcers of the cornea which begin from a minute centre without any herpetic phlycten. These are to be seen usually in cachectic cases—often in syphilitic patients—women who have been run down by over-nursing, in persons of intemperate habits, and in those who have been exhausted by fevers. They are usually deep and sharp-cut on the edges, with a narrow ashy margin and a greyish surface, and their disposition is to extend, like serpiginous ulcers elsewhere. They are very painful, but show little vascularity, and are difficult to arrest and dangerous to sight.

The indolent ulcer is extremely common in Ireland, especially in ill-nourished subjects and strumous children. The workhouses provide a large supply of such cases, which arise usually from a corneal herpes which refuses to heal. Ulcers of this class look like simple abrasions, and present no appearance of vascularity or inflammation. They are transparent, and, if small, are visible only by reflected light, the patient's vision being only a little blurred in consequence of the symmetry of the corneal curve being interfered with. There is not, however, any pain, and the patient is cognisant of the presence of the ulcer only by a sensation as if an eyelash was inverted and by the blurring of vision above referred to. These ulcers neither spread nor heal, and may exist for months if not cured.

The treatment of corneal ulceration must vary according to its character. The first thing is to remove granulations, or inverted lashes, or other mechanical hindrances to healing. The shrunk and hardened margin of the lid which remains after a granulation case has been cured often acts in this way, although the lashes may not actually be inverted, for the bowing of the lids caused by the conjunctival shrinkage causes its margin to press unduly against the corneal surface. The removal of mechanical irritants will cure all cases in which the constitutional condition is fair, but ulcers of the irritable or indolent classes need special treatment.

The irritable ulcer needs to be mollified by warm sedative stupes, and on no account should irritants be used. The compress bandage is also essential in most cases, and the ulcerated surface should be dusted with calomel. To do this a rather long-haired, perfectly dry, camel's-hair brush should be dipped in the calomel powder, which must itself be perfectly free from lumps. The lids being then held apart with left-hand finger and thumb, the brush should be held horizontally between the first finger and thumb of the right hand with the brush end opposite the ulcer. By giving it in this position a smart tap with the third finger of the same hand the powder will be thrown on the ulcer. The smaller the amount which adheres, the more evenly it is spread over the ulcerated surface, and the finer the powder, the better will be the result. Atropine solution should be applied diligently; but if there be imminent danger of perforation it should be discontinued, and solution of eserine substituted, for the purpose of keeping the iris away from the cornea and avoiding an adhesion if perforation should occur. In irritable ulcers the constitutional treatment is, however, the chief means of cure. Iodide of potassium in bark infusion, and, in syphilitic subjects, the bichloride or biniodide of mercury, combined with bark or quinine, are especially to be recommended. Iodoform often produces good results. The indolent ulcer, if it shows no sign of healing after the mechanical irritation is got rid of, can only be stimulated to heal by irritating it locally and by improving the constitutional state of the patient. The subjects of indolent ulceration are generally bad-fed, hard-worked, or strumoid cases, but without syphilitic taint or other serious depreciation of system, and they should, therefore, receive treatment as much hygienic as therapeutic. As regards local treatment, stuping, poulticing, or compresses will be inappropriate, but the ulcerated surface may advantageously be stimulated by touching it with the point of a brush shaken dry out of a 16-grain solution of nitrate of silver. This should be accompanied

by tonics, cod-liver oil, iodide of iron, and open air, and the most nutritious and digestible dietary enjoined.

When, under these influences, the ulcer commences to heal, it will lose its indolent appearance, and become more vascular and more grey in colour, the clean-cut transparent appearance of the indolent ulcer being lost. One of the most healthy signs is the presence of a lash of red vessels running into the bottom of the ulcer, as is depicted in the engraving.

Fig. 21. Indolent Corneal Ulcer (WARDROP).
(To be continued.)

Clinical Records.

CASE OF RETROFLEXION—PUERPERAL CONVULSIONS—RECOVERY.

Under the care of RIDLEY DALE, M.D. (Brux.), M.R.C.S., &c., Sunderland.

On February 27th, 1884, I was called to Mrs. D., who had engaged me to attend her in her second confinement, which she expected to take place at the end of March. She was twenty-two, and had with her previous child a normal pregnancy and labour. On my arrival at 6 p.m., I found her writhing in convulsions, the convulsive seizures occurring in series of three with intervals of a quarter of an hour. She was sensible between the attacks, but appeared in a dazed condition. On vaginal examination, the uterus was found much retroflexed and retroverted, with the os so high above the pubes that it could only be reached with the finger with great difficulty. I sent at once for my friend Dr. Murphy, and put the patient under the influence of chloroform, which stopped the fits. On Dr. Murphy's arrival, he coincided with me as to the nature of the case. I passed a catheter and drew off half an ounce of urine, which on testing was found to be free from albumen. We then gave a hypodermic injection of pilocarpine, and, as this did not cause much sweating, repeated it. As the urine drawn off was all the woman had passed that day, we considered the uterus was making injurious pressure on the kidneys and their vessels, and resolved to relieve this pressure by inducing labour. While I was maintaining anæsthesia Dr. Murphy dilated the hard and rigid cervix with his finger, drawing it down more on the axis of the pelvis. He then introduced a medium sized Barnes's bag (Sims's modification), and after an interval replaced this with a larger one. As she had no pains, a dose of ergot was given. Dr. Murphy then turned by the bipolar method and brought down a foot; the pains having now commenced, we resolved to wait a little to allow the cervix to fully dilate in the hope of getting a living child; but, unfortunately the funis became prolapsed, and delivery had to be at once effected. This Dr. Murphy readily accomplished by drawing on the foot, and a living female child was born. The placenta was expressed and another dose of ergot given, as the patient having now been six hours under chloroform we feared that there might be some hæmorrhage. Twenty grains of chloral was injected per rectum, and she was ordered to take a mixture containing chloral and jaborandi. Mrs. D. had no more convulsions until the next morning at 10 o'clock, when they occurred as before; the pulse was rapid and wiry, the breath urinous; she was unconscious, and the urine drawn off by a catheter less than half an ounce and contained 1-16th of albumen. We then administered another hypodermic injection of pilocarpine, which in five minutes caused a profuse perspiration and made the pulse slower and

softer, cupped the loins, gave croton oil (ʒv.) by the mouth, and inhalation of nitrite of amyl. She, about five minutes after this, had one fit, which was stopped by inhalations of chloroform. Ordered linseed poultices to the loins every four hours.

29th.—Had no fits; pulse slower and softer; bowels well moved; urine ten ounces containing 1-14th of albumen, sp. gr. 1020, turbid, under microscope contains blood corpuscles but no casts. Takes milk and barley-water. We gave another hypodermic injection of pilocarpine. Given a mixture containing liq. ammon. acet. and sp. æth. nit., and ordered to continue poultices.

March 1st.—She is conscious, asked to see the child, and replies distinctly and clearly to questions. Had no more fits. Bowels not been moved. Given another hypodermic injection of pilocarpine. She is taking plenty of milk and barley-water, and has passed naturally two pints of urine not containing albumen. Breasts are flaccid. Lochia normal. To continue mixture and take a powder of calomel and pulv. jalap co.

2nd.—Quite sensible, passed a good night, and sits up in bed. Urine clear and in normal quantity. Breasts contain milk and child put to them. To continue the mixture.

3rd.—Passed a good night. Urine normal. Bowels moved twice. Is able to suckle her child. To continue the mixture.

4th.—Passed a good night. To continue the mixture.

5th.—Passed a restless night. Bowels moved. To take acetate of ammonia and liq. ferri. perchlor.

6th.—Passed a good night, allowed to take some boiled fish.

7th.—Passed a good night. Diet increased to meat.

8th.—Sat up in bed for an hour to-day.

10th.—Ceased to attend as she feels quite well.

Remarks.—It appears clearly from the history of this case, that the cause of the convulsions, was the pressure on the kidneys of the displaced uterus giving rise to partial suppression of urine with uræmic symptoms. It was clearly necessary to restore the uterus to its proper position by inducing premature labour, to stop the convulsions and to get the kidneys to resume their work. The administration of chloroform checked the fits, but as the suppression still continued they returned, thus this was a valuable adjunct, but nothing more. The nitrite of amyl did not appear to have any effect at all. I attribute the recovery of the patient to the hypodermic injections of pilocarpine. The use of pilocarpine in puerperal convulsions has been highly recommended by Dr. Murphy. It caused here copious perspiration in five minutes, thus rapidly relieving the kidneys, and slackened the heart's beat and lessened the tension of the arteries. Oxytocic properties have been attributed to pilocarpine but in this case it did not cause any pains, so ergot had to be given. Pilocarpine is also supposed to increase the secretion of milk, and from this case, this appears to be true, for the breasts were quite flaccid up to the fifth day and then secreted plentifully.

Transactions of Societies.

CLINICAL SOCIETY OF LONDON.

FRIDAY, MARCH 14TH, 1884.

The President, Sir ANDREW CLARK, Bart., M.D., LL.D., in the chair.

Dr. SAMUEL WEST on a case of

MULTIPLE HEPATIC ABSCESS IN A BOY OF ELEVEN TREATED BY INCISION WITH RECOVERY.

A Jewish lad, æt. 11, who had never lived out of London, had a rigor on January 21st, and pain in the right hypochondrium. He was brought to hospital on February 20th with evident hepatic abscess, extremely ill, and with a temperature of 105°. On February 23 a large abscess was aspirated, and 18 ozs. of greenish sweet pus were removed. Four days later a free incision was made, and 7½ ozs. of turbid purulent fluid escaped; a second abscess was discovered and aspirated, when 1 oz. of blood-stained pus was removed. On March 6th the two last swellings were again prominent, and were

freely laid open, and a drainage-tube inserted. On April 9th a fresh abscess was found, explored, and then freely laid open. From this time convalescence commenced, interrupted only by a diffuse abscess in the abdominal walls, which healed alone on being opened and washed out. The points of the case were the following:—1. The age, 11 years. 2. The number of abscesses, three or four, and probably more. 3. The absence of any assignable cause. 4. The great relief by evacuation. 5. The rapid fattening during convalescence.

Dr. CARRINGTON, referring to the possible existence of idiopathic abscess of the liver, said he had collected many examples of the disease, and in three could find no primary cause for its occurrence. One of these was that of a policeman, whose liver was riddled with abscesses, and who was but five days ill. Another case, recorded in the *Pathological Transactions*, was that of a woman, who died of some other disease, but whose liver was found, *post mortem*, to contain numerous encapsuled abscesses. In a large proportion of these cases, as a rule, clinical symptoms were absent, the chief of these being tumid abdomen, with enlargement, and elevated temperature and feverishness. Last year Dr. Wilks had under his care at Guy's Hospital a woman who was supposed to be the subject of suppuration of the liver, her symptoms being vomiting, diarrhoea, and a temperature at times ascending to 103° or 104°. After death, it was found that cirrhosis of the liver existed, and Dr. Carrington concluded that a febrile temperature was probably more common in such cases than was usually supposed.

The PRESIDENT said that his experience did not lead him to expect that abscess of the liver would always suggest itself by the existence of the symptoms alluded to by Dr. Carrington. As an illustration of the meaning he wished to convey, he narrated the history of a case in point. The patient, a clergyman in the country, consulted him on account of illness from which he had been suffering for three weeks. Sir Andrew Clark concluded that a collection of matter existed in some place, and that to its presence the illness was attributable, but he could not make out its situation until, chancing to detect a small area over the liver, in which region a friction sound could be heard. On this evidence, he diagnosed abscess of the liver, and in confirmation thereof thirteen ounces of pus were evacuated on an incision being made. He had four times succeeded in detecting abscess of the liver by means of this method of diagnosis, which offered obvious advantages when taken together with the better known evidence afforded by the presence of pneumonia.

Dr. CULLIMORE said he had been himself a sufferer from abscess of the liver, and he concurred in believing this affection might be present and unattended by any abdominal enlargement or tenderness. In his own case the abscess was punctured, and discharged by way of the lung. He would like to know if abscesses of any size had been found to exist in the absence of fever, for in December last he was consulted by a gentleman who came from India, and who was supposed to suffer from abscess of the liver. He had no fever, but some tenderness was present, and a catch in breathing. Having been previously attacked by malarial fever, and there being no rise of temperature, Dr. Cullimore concluded there was no abscess present; and since the time referred to, the patient had noticed an occasional rise in his temperature, but unattended with sweating or jaundice. The tenderness and enlargement slowly subsided. Dr. Cullimore observed that, in his own case, he could not register any rise of temperature when he suffered from congestion of the liver, but that when that organ became the seat of abscess there was a distinct access of fever. He considered that abscess of the liver might be caused by the guinea worm, by aneurism following inflammation of the hepatic artery, and by accidental causes.

Dr. J. K. FOWLER remarked that he had drawn attention, twelve months previously, to the importance of sweating and pleurisy as signs of abscess of the liver. He had been led to puncture the organ from the presence of these signs in his cases, and as a consequence obtained a supply of pus. He considered that elevation of body-heat did accompany abscess, and as showing that absence of such rise indicated the absence of the disease, he instanced an experience obtained at the Middlesex Hospital, where a certain patient was supposed to have abscess of the liver, and puncture had been advised accordingly. Death occurred, however, before this was done, and then the liver was found to be the seat of amyloid degeneration, but it contained no abscess.

Dr. MAHOMED considered that two distinct classes of cases had been confused in the discussion—viz., large local abscesses, and small multiple abscesses, the latter a much more dangerous form, and having pyemic tendencies. Was not Dr. West's an instance of this class of case? He (Dr. Mahomed) recently saw at the Fever Hospital a patient who was recognised by a nurse as suffering from malignant multiple abscess of the liver. This attendant had been in Egypt during the late war, and had seen many cases of a similar nature. Patients so affected avoided lying in a way that led to pressure on the right side of the body.

Dr. PERCY KIDD described a recent case in which, although all the signs of abscess existed, no pus followed puncture. *Post mortem* three abscesses were discovered, the sole cause of which that could be found, was a caseous vesicula seminalis. The purulent collections were situated in the posterior part of the right lobe, in its lower margin, and a little behind it. The punctures were made both posteriorly and in the epigastrium.

The PRESIDENT said, that having diagnosed the presence of an abscess in the lung of a man at the London Hospital, he decided on puncturing for its relief, in the axilla, and as high as the area of dulness would permit. Relief was obtained, but the symptoms recurred so as to demand puncture afresh. This was performed by a surgical colleague who elected to direct the needle from before backwards. This manoeuvre was repeated four times, and each time without result. *Post mortem* each one of these punctures was found to pass within a quarter to half an inch from the abscess, which would infallibly have been pierced had the axilla been the site selected.

Mr. PARKER suggested that empyema might possibly be mistaken for abscess of the liver.

Dr. W. WHITE narrated the case of a gentleman seen by him last July, and who was suffering paroxysms of pain resembling gallstone colic. The temperature rose to as high as 102°, and the attack eventually subsided. No gallstones, however, were discovered in the *feces*. Subsequently, the same gentleman caught cold, had rigors; the liver became greatly enlarged; rise of temperature occurred, and loss of strength. On inserting a needle upwards and backwards a small amount of pus was evacuated from the liver, in three or four days the swelling subsided, and pain diminished, but soon all the urgent symptoms returned, and necessitated cutting down on the tumour, which was then cleared, and a drainage tube left in the wound. What caused the attack in this case?

Mr. GODLEE insisted on the high importance of keeping the discharges from hepatic abscesses as pure as possible. He had had two cases in which incision was followed by recovery. In tropical forms of these abscesses portions could be separated and partitioned off as it were from the general collection.

Mr. H. MORRIS said surgeons were agreed as to the value of free openings and thorough drainage. He inquired if, as a rule, abscesses opened through the intercostal spaces turned out unsuccessfully, and whether such as were reached by puncture below the level of the thorax did well?

Mr. GOLDING BIRD observed that, of his last three cases, two died, and in each he had selected an intercostal space as the site of opening. In the third, a successful case, the opening was below the chest level. Death, however, had occurred in one case treated by the latter method.

Dr. WEST, in reply to Mr. Parker's criticism, ventured to place reliance on his own diagnosis of the case, with which, had Mr. Parker seen it, he considered he, too, would have concurred. In the case recorded, the temperature rose on several occasions to 103°, but he saw no reason why similar conditions should not obtain in this, as in other diseases, and its presence be unannounced by elevation of temperature. He had seen many cases in which high fever did not accompany collections of pus. Murchison had published the fact that cirrhosis was attended by an intermittent temperature. The same author had also pointed out the distinction insisted on by Dr. Mahomed between single and multiple abscesses. Dr. West agreed that openings in the intercostal spaces were attended with greater danger than those in the infra-diaphragmatic region; and all the operations he had seen in the latter part did well.

Mr. BUTLIN on a case of

ŒSOPHAGOTOMY PERFORMED FOR THE REMOVAL OF A FOREIGN BODY FROM THE GULLET.

The patient, a man, æt. 45, swallowed a gold plate,

bearing four teeth and having two long pins, during the night. The plate was impacted opposite the cricoid cartilage, where it produced serious spasmodic attacks of dyspnoea and constant dysphagia. Since it could not be dislodged by means of forceps, &c., cesophagotomy was performed about twelve hours after it had become impacted. The plate was removed without difficulty; the patient progressed well during the first two days after the operation, then rapidly died of acute septic poisoning. Attention was particularly drawn to the difficulty of detecting the nature of an impacted body by sounding; to the difficulty of seizing the plate with forceps; to the results of swallowing fluids after the operation. It was contended that the unfortunate issue of this case ought not to influence the general rule of treatment in similar cases—namely, that cesophagotomy should be performed as early as possible after the impaction of the foreign body, if the body were hard and sharp, and it was evident that it could not be removed by less formidable means. The cases of cesophagotomy for the removal of foreign bodies did not show a large mortality from septic poisoning; indeed, the reverse appeared to be the case, for unless septic poisoning was produced by the presence of the foreign body, it had been rare as a result of the operation.

Mr. CRIPPS considered that no doubt could be entertained as to Mr. Butlin's treatment being most appropriate under the circumstances, and that it was the only possible plan to be followed. There was, however, a very important class of cases in which the obstruction occurred at a lower point than in that under discussion—*e.g.*, when a foreign body lodged in the thoracic portion of the cesophagus. In such cases the question arose whether it was better to make an opening in the neck, or to push the body on into the stomach. The latter proceeding appeared to him to be more rational, since experience showed that most unlikely articles could be safely passed through the alimentary canal and expelled *per anum*; as instances might be cited the case of a gentleman who recently passed a large tooth plate in this way, without pain; and that of a girl at St. Bartholomew's Hospital, who, while tickling her fauces with a bonnet pin, six inches long, and provided with a knob at the end, her object being to induce vomiting, accidentally swallowed the instrument. On admission, pain and tenderness over the abdomen were complained of; but no foreign body being discoverable, the case was regarded as one of hysteria, and the patient discharged accordingly. A fortnight later, she returned with a small abscess pointing on the epigastrium, which being opened, the pin was extracted, minus its head; complete recovery took place.

Mr. GOLDING-BIRD remarked that an astonishing number of cases had been recorded in which tooth plates and other formidable objects had been inadvertently swallowed without ultimate ill effects. A patient of his own, two years ago, swallowed such a plate, and, having stuck in the cesophagus, it was passed into the stomach by a probang, the operation occupying one hour. He was then fed for two days on oatmeal, and at the end of this time the foreign body was passed by the anus. Periccesophageal abscess followed, but recovery ensued.

Dr. GLOVER described a case in which he was consulted by a lady, who had swallowed a piece of bone with some soup, the accident occurring twenty hours before Dr. Glover was called in. The patient was then in great distress, and quite unable to swallow anything. The obstruction was quite beyond reach, and an emetic, consisting of half a drachm of zinc sulphate, was administered. This having no effect, a second dose was given, and vomiting immediately occurred; and there was discharged through the mouth a piece of mutton bone, quite an inch long, and having four sharp corners and edges. Dr. Glover advised that that should be the mode of treatment in future cases.

Mr. E. OWEN asked why Mr. Butlin delayed to operate for so long a time? He lately saw a woman who had swallowed a much larger plate than the one exhibited; it had passed into the stomach.

Dr. DUFFIN said that the late Professor Syme, of Edinburgh, once had under his care a boy, who, in the excitement of fishing, swallowed a three barbed hook he was holding in his mouth, a wire being attached to the hook. Professor Syme adapted a wooden ball to fit the barbs, and passing it along the wire succeeded in breaking away the points, after which the hook was easily removed, and recovery ensued.

The PRESIDENT said he also remembered a case of Syme's,

in which a man had swallowed a tooth plate, and in forcibly propelling it on by means of a probang, the surgeon accidentally ruptured the aorta, from which a rush of blood immediately took place, and speedy death of the patient.

Dr. GLOVER mentioned a further case which occurred during the time that he was a student. It was that of a man who had swallowed a bone, and in the result an abscess formed, followed by death.

Mr. BUTLIN said he had purposely confined his remarks to that class of cases in which the foreign bodies were lodged high up in the cesophagus. Abscesses formed in a good many cases in which the body was removed. He had purposely abstained from inducing sickness in his patient; and his reason for deferring to operate was, that he felt disinclined to submit the patient to the necessary risks in his consulting room, and waited, therefore, until he could command the resources of a large hospital in his favour. Further inquiries had convinced him of the abstemious habits of the patient. As a result of recent experiments he found that gold plate could be easily broken after being submitted to the action of mercury.

LIVERPOOL MEDICAL INSTITUTE.

FRIDAY, FEBRUARY 29TH.

Dr. GEE, President, in the Chair.

Dr. GREVES showed pathological specimens from
TWO CASES OF TUBERCULOSIS IN CHILDREN,

Case I., *et. 2*, was admitted into the Infirmary for Children greatly emaciated, the mother was phthisical. There were no abnormal physical signs either in thorax or abdomen. Being unable to take food by the mouth she was fed on nutritive enemata of pancreatised milk. She made no progress however, and gradually sank. At the post-mortem examination, there was general cheesy degeneration of the bronchial and mediastinal glands, tubercular deposit beneath the left pleura, and slight enlargements of the mesenteric glands; there were scattered nodules also in the liver, spleen and kidneys. *Case II.*, *et. 3*, admitted into hospital, with advanced catarrhal pneumonia on January 29th; there were signs of consolidation with breaking down of the right lung, and great emaciation. A week afterwards the temperature began to oscillate greatly, rising to 103°, or 104° F. in the evenings, and falling to 94° or 95° F. in the mornings, he got rapidly weaker and died on February 26th. *Post-mortem Notes.*—Right lung partly collapsed, consolidated and riddled with cavities, one of which in the base communicated by a large orifice with the pleural cavity which contained some ounces of pus. There was general enlargement of the lymphatic glands in thorax and abdomen, tubercular ulceration of intestines with tubercles in the other viscera.

Dr. MACFIE CAMPBELL showed the following specimens from

TUBERCULAR DISEASE OF TESTICLE—CASTRATION.

I. C., *et. 38*, sailor, was admitted into the Liverpool Northern Hospital; phthisical history. Received an injury to the testicle at sea five weeks before operation. The right organ became hard, swollen, and inflamed, requiring opening of two abscesses in the scrotum. No improvement taking place, while his general condition was gradually becoming worse, and cough beginning, it was considered better to remove one cause of irritation. After removal, the following condition of the organ was found: Tunica albuginea much thickened, tubules obliterated, as also septa, vasa recta and vasa afferentia, Epididymis from globus major to minor, simply the bag of an abscess, containing thick, curdy tuberculous pus. Size and weight about double the normal.

Dr. MACFIE CAMPBELL on a case of

OLD EMPYEMA—NEUROBOSIS OF RIB—CALCAREOUS PLEURA—FREE OPENING BY REMOVAL OF PORTION OF RIB—DEATH.

I. E., *et. 58*, admitted into the Liverpool Northern Hospital; family history good, received injury to ribs by engine-buffer sixteen years ago, remained well until two years ago with exception of occasional sinuses along the level of the ninth rib. Admitted January 22, 1884, suffer-

ing from cough, and large abscess three inches below and behind right nipple. Opening was found into the pleura, evacuating 1½ pints of filthy pus. The pleura was found calcareous, no lung could be felt, the cavity was syringed out at first with carbolic lotion (1-40) then by perchloride of mercury (grs. 1-10 to the ounce). Died suddenly with symptoms of obstructed breathing on February 18th. *Post-mortem*.—Right lung, healthy, congested at base; left lung, represented by a thin stripe of connective tissue adherent behind; costal pleura entirely calcareous, detached above, dividing cavity into two parts, and extremely thick; heart, right side, large ante-mortem clot; other organs normal.

THE HEART IN ANGINA PECTORIS.

DR. BARR exhibited the heart of a patient who had died from angina pectoris in Her Majesty's Prison, Kirkdale. It weighed 14½ ozs. and was soft and flabby. All the cavities contained dark fluid blood, and in the right ventricle there was a discoloured clot matted in the chordæ tendinæ but it did not stretch into the pulmonary artery. Pulmonic valves healthy, right ventricle large, walls pale and marked with fatty striatum. Tricuspid valves healthy, orifice admits five fingers; right auricle large, walls pale and fatty.—Left ventricle, walls soft and flabby. Muscular structure pale and fatty, musculi papillares and columnæ corneæ fatty; aortic valves competent; above the left anterior cusp, and involving the left coronary artery, there is a large atheromatous patch which includes the mouth of the artery. Mitral orifice admits three fingers, valves healthy, left auricle large, walls pale, soft and fatty. The history of the case may be briefly stated thus:—This man gave his age as 47 years, though he appeared at least 10 years older. He made very few complaints, but was unable to walk quickly or undertake any active exertions. The night prior to the attack which caused his death he suffered from great pain and oppression on the chest, and a feeling of impending death. On the night before death, he was cold, clammy, and suffering severe anguish, pulse weak, small and irregular; he complained of severe pain over the heart and shooting down left arm. He was troubled with cough and much profuse frothy mucous expectoration tinged with blood. The cough and bronchorrhœa were effectually relieved by nitrite of amyl. He had also nitro-glycerine and hypodermic injection of morphia, which relieved the angina, but he died the following day from failure in the heart's action.

Dr. HOWIE read a paper on

THE INFLUENCE WHICH THE PRESENT SYSTEM OF EDUCATION HAS UPON THE HEALTH OF THE COMMUNITY.

He held that it is the duty of medical men to insist upon the evil effects which are certain to follow if the present course is persistently pursued. Confining his remarks entirely to children under twelve, he said that no such child ought to be called upon to perform any kind of work whether muscular or mental. That four hours *mental exercise* is enough, twelve hours in bed, four hours for meals, &c., and four for muscular exercise. That much as he believed in education as a means of national improvement, yet it would be better to leave the masses uneducated, than to train their minds at the expense of muscular strength and dexterity. Reading and writing, although extremely important, yet were not absolutely essential to the highest education, that facts themselves without the ability to think and speak correctly about them are of but small advantage in mental training. Under the existing educational code, teachers are compelled to force into the minds of their pupils information for which they are utterly unprepared either by age, or by previous training. That the blame rests on the framers of this code who have utterly ignored the brain capacity of children, and not on the school-master or inspector who are simply acting in accordance with their directions. Throughout the whole course of a child's school career, most of the subjects of study are quite beyond his intelligent grasp, unless he is specially precocious. He then described at some length, the influence which close confinement in school rooms had upon the health by inducing a tendency to frequent bronchial catarrhs, which in children of phthisical history will ultimately lead to that disease, and quoted several cases from his own experience in support of this. He also spoke strongly in favour of the half-day system of schooling. In our elementary schools it is not so much actual over-work as excessive stimulation of a growing brain which leads to its far too rapid growth to

be healthy, the nerve structure is through this rendered extremely sensitive and lacks stability. In order to remedy the present system he suggested that first of all, we ought to choose good teachers and give them a considerable amount of freedom in dealing with the pupils, and to abolish the system of payment by results. He therefore proposed that a committee should be appointed by the Institution to inquire into the question of over-strain in elementary education.

This resolution was carried unanimously.

THE SHEFFIELD MEDICO-CHIRURGICAL SOCIETY.

THURSDAY, FEBRUARY 7TH, 1884.

The President, Dr. BANHAM, in the Chair.

THE following improved apparatus were shown:

Dr. DYSON showed a very neat form of Portable Scissors, in which, when closed by a sliding arrangement, the blades are enclosed in sheaths which afford complete protection from injury by the points. He did not know the maker's name; the pair shown came from Brighton.

Mr. SNELL exhibited an India-rubber Cupping Instrument which seemed very effectual indeed in its action, and affords a ready method of applying this method of treatment. Mr. Snell also exhibited a Nettleship Ophthalmoscope.

THE PRESIDENT showed a Circular, printed 1842, summoning a first meeting of the Session, of the Members of "The Medical Society of Sheffield, and its Neighbourhood," sent to a Mr. Turton, a noted obstetrician in Sheffield in those days. The meeting was called for October 3rd, 1842, at the Cutlers' Hall. The Secretary was T. Hammer Smith. On the back of the Circular was the statement of arrears, Mr. Turton being indebted to the amount of a fine of 1s.

CASE OF ATHETOSIS.

Dr. DYSON showed a case of *athetosis* (inability to maintain a fixed position) of the right arm, and in a much less degree, of the right leg. The patient, a girl, æt. 11, had scarlet fever three months ago. About six weeks ago, she was seized with an apoplectic form of attack, in which there was loss of consciousness, paralysis of right side of the face, right side of the tongue, right arm and right leg. She was confined to bed for a fortnight, and as the paralysis passed off the present condition of the right arm gradually supervened. Sensation is but slightly affected. The movements are slow and deliberate and intensified by exertion, and are exactly those described in typical cases of *athetosis*. There was no history of rheumatism. The heart is healthy. The urine presents no abnormal conditions. In this case there is a history of the girl having been bullied by the School Board attendance officers to return to school too soon after the attack of scarlet fever.

SPECIMEN OF LIVER WITH CARTILAGINOUS NODULE.

Mr. H. LOCKWOOD, Junior House Surgeon, Sheffield Public Hospital and Dispensary, showed a specimen of the above, and read the following notes:—The patient, æt. 59, was admitted into the hospital under the care of Dr. Dyson, on October 11th, 1883. He had enjoyed good health up to two months ago, when he became rapidly swollen, and experienced great difficulty of breathing. On admission there was great œdema of the legs and abdomen, but not of the upper extremity. There was increased cardiac dulness, and a very well marked aortic regurgitant murmur. His arteries were very atheromatous. The abdomen was tense and fluctuating. The patient gradually became worse and died two months after admission. On a post-mortem examination his heart was found to be very much hypertrophied, and the valves and aortic arch atheromatous, but there were no evidences of considerable valvular mischief. On the under surfaces of the right lobe of the liver a hard nodular tumour was found embedded in a cavity lined by a capsule. The outside of the tumour was hard, and on making a puncture a caseous material exuded. On section, the walls were found very dense and hard, and the tumour presented the appearance of a cystic tumour in which calcareous change had taken place in the walls, and caseous degeneration in the contents. The specimen was referred to the Pathological Committee for examination and report.

OSTEO-SARCOMA OF THE FEMUR.

Mr. ATKIN showed a rapidly-growing sarcoma of the lower end of the femur, which had been amputated at the hip-joint that day by Mr. Favell, and commented on the diagnosis, saying that these rapidly growing soft vascular sarcomata had often been called true aneurism on the one hand, and mistaken for periosteal abscess on the other. The tumour, which sprang from the junction of the epiphysis with the diaphysis, showed a well-marked radiated arrangement from the axis of the vessels, and posteriorly towards the intercondyloid notch was of stony hardness, whilst in front and to the outer side it consisted of a soft, easily breaking down vascular mass. The boy, *æt.* 17, had only noticed it since Christmas (about seven or eight weeks), and it was probable the calcified part was of much longer growth, though not having caused sufficient inconvenience to attract notice. The proneness of these growths to attack long bones at the end where ossification first commences, the end which is last joined to the shaft, and at the opposite end to which the nutrient artery is directed, was mentioned. The probability of recurrence was great, for, differing from a central sarcoma of bone, the contiguous muscles must be affected, and that as long as the origins of these muscles were left, the growth would probably recur in the wound. As illustrating the difference from central tumours of bone, the lymphatics in the groin in this case were slightly enlarged. The seat of amputation ought to be as high up as possible, as it is only in myeloid tumours or central sarcomata that scooping or amputation near the seat of the disease is of any value.

ENLARGED CLITORIS.

Mr. ATKIN also showed for Mr. Favell an enlarged clitoris removed from a girl, *æt.* 13. The growth was recent, and accompanied with slight vaginal discharge and much inconvenience in walking, though no pain. The internal genital organs were abnormal, the vagina being rudimentary.

ABSCESS IN EPIPHYSIS OF THE KNEE, THE FEMUR, OPENING INTO JOINT.

A specimen was also shown of acute arthritis, from the knee-joint of an infant, a patient of Mr. Jackson's, who had excised the joint that afternoon. Following a slight injury, an abscess formed in the lower epiphysis of the femur, which ultimately bored its way through the articular cartilage into the joint.

CASE OF IDIOPATHIC ANÆMIA.

Mr. R. J. PYE-SMITH related the sequel to a case of idiopathic anæmia, which he had brought before the Society last year. The patient, a man, *æt.* 61, remained well for a couple of months after treatment (by arsenic) was discontinued. He then began to complain of a fulness in the right inguinal region, and a week later, after getting drenched with rain, he experienced stiffness and pains all over, which were soon followed by tottering gait, difficulty in turning whilst walking, and, later, by severe sudden pains in the limbs, chest, and abdomen. The signs of inco-ordination in the legs were well marked, as also the loss of knee-jerk and of other muscular reflexes. Contracted pupils, the existence of slight numbness in the feet and hands, together with the absence of wasting and of much loss of power in the muscles, rendered the diagnosis of locomotor ataxy clear. Arsenic failed to produce any effect on the symptoms. Mr. Pye-Smith regarded the association of disease as a mere coincidence, and thought that the history of grasping pain at the chest and numbness of the feet which the patient had previously given, pointed to the disease of the spinal cord having commenced previous to his coming at first under observation.

France.

[FROM OUR SPECIAL CORRESPONDENT.]

SULPHATE OF COPPER IN OBSTETRIC PRACTICE.—At the Académie de Médecine, M. Charpentier read a paper on "Sulphate of Copper in Obstetrics," and deduced the following conclusions:—1. Sulphate of copper is an antiseptic of the first order, and renders signal service to obstetri-

cians. 2. It is cheap, and easily used by the most inexperienced hands. 3. Of complete innocuity whether employed under the form of intra-vaginal injection, or intra-uterine. 4. That sulphate of copper, from its astringent properties, could advantageously replace perchloride of iron. 5. The solution employed should be a one per cent. 6. The solution at this strength might be continued eight or ten days without producing more than a diminution of temperature, and a fall in the pulse. Lastly, surgeons would do well to try this antiseptic, which would give them every satisfaction.

FIBROUS TUMOUR OF THE UTERUS.—M. Pozzi exhibited before the Société de Chirurgie the anatomical specimens of a fibrous tumour of the uterus, and a cystic tumour of the left ovary. The case was of some interest, as it was accompanied with hysterical phenomena of a very marked character. After the operation all those symptoms ceased, and M. Pozzi asked his colleagues whether castration was not in such cases differently considered. M. Terrier thought the question was difficult to solve, as the operation, although accepted in other countries, has not many partisans in France. However, he believed that there were certain indications that might justify it. He regretted that the case of M. Pozzi was incomplete, in that the two ovaries were not removed. A fortnight ago, he took away the left ovary of a young woman for a polycystic tumour, and the patient, who was always a little nervous, was attacked after the operation with the most violent hysterical fits. M. Reclus said, about two months ago he took away *both* ovaries for cystic tumours. The patient, who was habitually hysterical, became uncontrollable after the operation, and it was only after a fortnight had elapsed that the violence of the attacks diminished. M. Gillette thought that Battey's operation was not at all justified when the ovary was healthy. It was practised twice in France, and with no good result. M. Pozzi concluded the discussion by saying that an operation that was classic in England, Germany, and America, should not be wholly condemned in France.

PRURITUS AT THE MENOPAUSE.—The pruritis so often observed in women at the menopause, or change of life, is well known to be excessively rebellious to treatment, and the suffering caused by the affection, morally and physically, is often very serious. It is nothing uncommon to see women in the greatest prostration and despondency from the loss of sleep and appetite produced by an insupportable itching. The practitioner has often been disappointed at the little result obtained from the employment of remedies recommended by the greatest authorities, and both patient and attendant despair of success. Dr. Cheron highly recommends the following ointment where the pruritis is localised to axilla, the vulva or thighs, or the abdomen. He declares that if this pomade is applied morning and evening the affection will yield to its influence.

Veratrine, *grs.* iij.;

Axunge, " 8j.

When the pruritis is general over the body, he advises the veratrine to be given internally in pills.

Veratrine, 1-3rd *gr.*;

Liquorice powder, *q. s.*

For 40 pills, 2 to 6 a day.

SIR LYON PLAYFAIR, K.C.B., has consented to allow himself to be nominated at the Montreal meeting of the British Association as President for the meeting to be held in Aberdeen next year.

Department of Lunacy.

THE QUESTION OF TRAINING ATTENDANTS ON THE INSANE.

WE have recently directed attention on more than one occasion to the efforts being put forth in the interest of attendants on the insane, and to the natural expectation that these efforts will ameliorate the condition and promote the recovery of the patients entrusted to their care. The question is a very wide one; and the aspect of it which has of late been receiving the attention of the profession, especially in Scotland, is but a segment, though an important one. Medical men are fully alive to the immense importance of the matter, and frequently experience the great responsibilities entrusted to attendants and the serious issues dependent on their vigilance, intelligence, and moral character. But to turn asylums into training schools for attendants, and to introduce to the latter more intellectual views of their patients, are ideas that will probably at first sight be received with caution. It is hard to put aside tradition and precedent all at once; and it would be foolish to set about such a revolution without counting the cost. We are nevertheless bound to analyse traditions and precedents carefully, as well as our more modern ideas; and it is not unusual to find the former grown old and narrow and unreliable. It is better to take the swing of a new idea at the beginning and keep a judicious control of it than be carried away by it when too late to inhibit its force. The possibilities for good intact in such an idea are immense; yet there is a danger of it running to seed for want of proper direction and combined exertion. The possible arguments against it are no less numerous, but experience will be the best test of their truth or fallacy.

This training question has resolved itself into three distinct, but not independent, divisions. These are, ward instruction, a manual of instructions for attendants, and systematic clinical lectures to all. Ward instruction deals with individual attendants, and is liable to be conveyed chiefly to the charge attendant who accompanies the doctor when making his visit. A manual will make an excellent supplement convenient to junior and senior attendants, but of itself insufficient to stimulate inquiry and develop the best energies of all the attendants. Lectures *per se* will succeed or fail according as the lecturer is interesting or dry, clinical or formal, practical or abstruse; and lectures cannot stand alone any more than can a hand-book of instructions. Ward instruction is dealt out more or less in all asylums, but it is nominal rather than actual and real. Its measure will be determined by the energy of the teacher, by the time at his disposal in visiting his patients, and by the absence or presence of distracting and annoying events during the visit. At its best, it can reach only a favoured few; and unless associated with other 'methods', will bring discredit on the name of training as it should properly be understood. The impression grows upon us that a training which will justify the name must have each of these three methods entering into its composition; but the component parts of it will themselves enlarge with the exercise of their respective functions, and certain worldly advantages to attendants must obviously follow. The higher development of attendants is, however, not quite a new idea. The names of the late Dr. Kirkbride, of Pennsylvania, the venerable Dr. W. A. F. Browne, of Dumfries, and others, naturally come into prominence in considering the subject; but we gladly acknowledge the vigorous impetus which has been given to the movement by Dr. Campbell Clark's recent labours and writings on the subject.

We welcome the prospect of a manual of instructions being issued shortly, and hope to find it a valuable aid to the higher training of attendants.

The impression must not prevail that in such a scheme we have the whole root of the matter, for, though presently submerged by the prominence assumed for educating attendants, there exist other and no less important considerations for us to look into. How, for example, should our attendants be domiciled? Have they received such consideration in this respect as the nature of their duties require? This is a very important question; and so are questions of hours on duty, hours and days on leave, attendants' special recreations, and various details, apparently trivial in themselves, but all contributing to emphasise distinctly congenial surroundings as compared with hardship and discomfort. We have, moreover, to bear in mind that the dismissal of attendants is frequently too summary and inconsiderate, and this renders an attendant's position one of insecurity inimical to their special education and social elevation. The discipline of our asylums should not approximate to the discipline of a jail, but should be consistent with the most favourable conditions for battling with disease. The more intimate and cordial the relations—consistent with good order and discipline—which subsist between the medical staff and the attendants, and the more unity of purpose is achieved and fostered, the greater will be the success of asylums as hospitals for the insane, and as training schools for attendants.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, MARCH 26, 1884.

WHAT IS A CONSULTANT?

A CASE of some interest to the profession was decided last week before Mr. Justice Hawkins, and which, as

affecting the definition of the word consulting in its application to medical practitioners, raises a point of considerable importance. The parties to the suit were, on the one hand, Dr. Alfred Carpenter, of Croydon, and, on the other, Drs. Whitting and Lanchester, Dr. Carpenter's late partners in practice. By an agreement executed in May, 1877, the latter gentleman bound himself, in consideration of a payment of £5,000, to retire from general practice on Jan. 1, 1883, but reserved to himself the right of advising patients attending upon him at his residence in Croydon, and of acting as a "consulting physician." For the plaintiffs, it was contended that Dr. Carpenter had contravened the terms of this agreement by, as was admitted by him, attending patients singly; and in the result an arrangement was arrived at whereby the plaintiffs accepted judgment in their favour for £50, with the understanding that Dr. Carpenter would henceforth carry out the literal intention expressed in the following statement, issued to his patients, as follows:—"I shall only visit cases at their own residences when residing in the Croydon district, in consultation with other medical men, such being the engagement entered into with my late partners, and that in the future my position will be that of a consulting physician, and not that of a family attendant."

It is not in any way questioned that Dr. Carpenter's action has been for a moment intentionally destructive of the meaning of the engagement he contracted with his partners, but the whole circumstances have arisen in connection with the meaning to be attached to the word "consulting" in respect to medical men. That there is nothing to be found in the *littera scripta* of professional ethics to determine exactly what this term conveys, is generally admitted; but, nevertheless, it may be safely assumed that an almost universal understanding obtains concerning it, and that its application is limited to a distinct class of practitioners who hold a position apart from those who are distinguished as "general." It would seem, however, that some physicians at least do not accept the conclusion here affirmed, Dr. Norman Moore having declared in evidence before Mr. Justice Hawkins that he was unable to name a person who was called a consulting physician. The meaning such a term conveys to his mind is, he further explained, that a physician holds his office like a professor, and is precluded from practice. It is possible, however, that this statement is not accurately reported, for its author, from the position he occupies, must necessarily be familiar with the fact that it is unusual for medical men to express any opinions on the nature of cases that they do not personally examine; and the mere examination of any person suffering from an illness constitutes, by all the canons of medical logic, an exercise of those faculties the use of which is the "practice" of a physician. What Dr. Moore is described as having stated is equivalent to the assertion that a consultant cannot be a practitioner; and, as all medical men are practitioners, none can possibly be a consultant. Surely, however, this is not so; and it is possible for one and the same person to enjoy a right to both titles; and further, we are ourselves unable to grasp that idea

which bases itself on the abstract existence of a consulting physician who, by reason of his being so, is therefore a *non-practitioner*. There is an inextricable confusion in this mode of reasoning, which will hardly commend itself to many, and which has seemingly had its origin in an unjustifiable dislike to the introduction of distinctive terms, which have certainly done no harm in the past, and will not probably be found injurious in the future.

A very considerable number of physicians and surgeons, as they attain the professional eminence to which their skill and intelligence entitle them, are compelled by the pressure of work thrust upon them to forego what is rightly named "general" practice, and to confine themselves to consultative engagements. Such practitioners' usual duties are to visit patients for the purpose of assisting the judgment of the ordinary attendant; to advise treatment, and in case of surgeons to determine the need for, and possibly perform, operations. Furthermore, they receive at their own consulting rooms such patients as can, and choose, to "consult" them on the subject of their maladies; and in a great majority of such cases the patient is either accompanied by his own regular medical adviser, or has been preceded by a letter from the latter explaining the details of the case. It is hardly necessary to say that such practitioners as have attained to a position in which their time is spent in such a manner as is here sketched out will have no leisure, and others, even if they have this, are without inclination, to indulge in those indiscriminate visits to anyone and anywhere they may be called to at a moment's notice, and which is essentially general practice in contradistinction to consulting practice.

It might easily have been supposed that no possible necessity for making these comments could have arisen, and that the whole medical profession was agreed upon the meaning to be attached to a term so frequently applied to many of its members. That this is not the case, however, has now been proved, not only by Dr. Moore's explicit utterances, but also by the statements of other equally eminent authorities on the same occasion. Dr. Wilson Fox, for instance, though admitting that he had not previously considered the question, could not think of any consultants save those so named on the staffs of hospitals; and his non-acceptance of the distinction is apparently based on the non-recognition of the title by the Royal College of Physicians. Dr. Fox, however, will go a little further than Dr. Moore; not for while the latter will accept any use of the term, the former does say that the term "consulting" is used in a double sense—technically, when two medical men meet in consultation, and popularly, when a patient consults a physician. But he emphatically insists that no such term exists in the profession as consulting physician. Dr. Fox will probably, as is implied in his evidence, admit that consulted physicians exist, however, if but for the purposes of special consultation; and it seems almost worth while, seeing to what confusion the want of some such distinctive attribute can at times give rise, to adopt the disputed word into common use by accepting its definite applica-

tion to all those practitioners whose active labours are of the nature specified above.

Such a plan will, unquestionably, be objectionable in some respects, inasmuch as it would seem to create distinctions that could not fail to be invidious in certain instances; and in the attitude assumed by Dr. Moore it is easy to perceive a generous wish to relieve the profession from every appearance of such a description. While admiring the feeling which animates him, however, and duly appreciating the anxiety it exhibits to promote healthy *esprit de corps* by levelling barriers that promote distinctions, we are unable to lose sight of the fact that in spite of all attempts to the contrary within the profession, the laity without will persist in a practice which has been for so long past prevalent, and will hold to their own method of classifying medical men. If their action in this respect can be assisted in a right direction by the general voice of the profession itself, a gain will surely be effected; and especially if the younger generation of practitioners is assisted by the question of fees being at length placed on a firm basis, whereby they will not be injured by the competition of "consultants," popularly so-called, consenting to accept such payments as are usually only received by general practitioners.

The termination of the case which has evoked these remarks is itself a confirmation of the opinion we have expressed. It assigns to Dr. Carpenter the position of "consultant;" and though the profession of medicine will not be in any way bound by the decision arrived at in a court of law, still it will hardly fail to have some bearing on individual opinions. As far as the case itself is concerned, it might have been better, perhaps, had it been settled in private; but inasmuch as the question is an interesting one, and in no way reflects on either party through being raised, save in the matter of opinion, it is scarcely possible to regret that it has been made subject of a legal settlement.

THE MEDICAL BILL.

The Committee stage of the Bill in the House of Lords was got through on Thursday evening last without opposition, but with some foreshadowing of trouble when the measure reaches the Commons. The Government introduced three changes into the Bill of last year, *i.e.*, they gave the Scotch Corporations five instead of three representatives in the Local Board, as against eight University representatives; they gave the Irish College of Physicians a third representative on the Irish Board, and added also a representative to be elected by the two Irish Universities collectively; and they made a step towards securing uniformity of educational and examinational standard throughout the Kingdom. The concessions thus made to the demand for a revision of the constitution of the Local Board is a recognition of the strength of the outcry which the Corporations in Ireland and Scotland have made against the unjust predominance given to the Universities in these countries. Certain critics have spoken of the relative strength of the Universities and Corporations as an insignificant detail,

and have sneered plentifully at those who made a noise about so small a matter. But those who have thus written seem not to have considered the fact that the Bill—most unwisely, as we believe—gives into the hands of these Local Boards the making, control, and supervision of the future medical education of the Kingdom. Nay, the Bill does more than this, for, while it excludes from these Local Boards the independent voice of the Crown, and of the profession at large, it gives into their hands the appointment of the Central Council, and greatly limits the power of that Council over them. Thus it becomes a matter of supreme importance to secure a fair balance of power in these Boards, and hence the struggle for influential representation in them. We may speculate, for instance, upon the possible result of a strong voting predominance of any one party in the Irish Local Board. That predominance was given, without any tangible reason, to the Universities, and it would thus have been possible for the University party, voting together, to minimise the importance of the subjects taught or examined on by the Colleges, to exclude collegiate men from examining boards, to starve out the Colleges by fixing the fees at such a level that they could not live, and finally to vote none but University men into the Central Council. We don't say these things would be done, but we say the Colleges are wise to contemplate such possibilities, especially as the appeal which the Bill offers them to the Central Council and to the Privy Council is but a poor guarantee against such proceedings.

The new clause which is to provide that the educational and examinational requirements of each Local Board shall not descend below a minimum is as follows:—

Any scheme under this section shall be framed in such manner as to secure, so far as is practicable, as between the several parts of the United Kingdom, a substantial equality of standard as respects education and examinations.

The least that can be said for this clause is that it is better than nothing. It pronounces that the standard of education and examination shall be "substantially equal," and thus gives rather a hint than an instruction to the Central Council to keep any one Local Board from underselling the others in education and in severity of test. It is to be hoped that the hint will be acted on when the time comes.

During the debate two warnings were given as to future opposition to the Bill, one by Lord Balfour of Burleigh, on behalf of the Scotch Universities, who would like them to continue in the enjoyment of their present happy condition, and one by Lord Limerick, who expressed his belief that the University of Dublin would not be content to "split" a representative with the Royal Irish University. But a much more serious hindrance in the path of the measure is the unexpressed determination of the Irish College of Surgeons not to allow the Bill to go forward unless some means are taken to put the student under the control of a medical authority during the whole period of his study. The College had an amendment on the paper

providing for this which it did not press, because of the probability of its being outvoted, but it declares its intention of urging that amendment in the Commons with all the influence which it can command. The contention of the College is that, under the Bill, it will be open for a student who pursues his education no one knows where, and passes primary examinations indefinite in number and in educational standard, before an "examining body" of unknown *locus* and untried capacity for testing, to come up to the Local Board for final examination and go out into practice without in any way associating himself with any of the recognised educating or examining bodies of the country. The College, therefore, asks that the student should be obliged to attach himself to some one or more such institutions from his first day of pupilage, and to go forward through his primary examinations under the supervision and responsibility of the institution. This seems to us a proposition alike reasonable and practical, and we hope that the Government will see its way to prevent the threatened opposition by accepting it.

The Medical Bill will probably pass into the Commons this week, and the moment will then have arrived for the negotiation of friendly amendments. In many details the measure is greatly at fault, and there is no reason why improvements should not be made without hostility or without any delay of progress. We call upon the British Medical Association, when the measure has reached this stage, to do its duty to the profession by seeing that these changes in the Bill are made before it becomes law, and we take upon ourselves to say that the practitioners of Great Britain will hold the Association responsible for every fault which remains in the Bill. Hitherto the profession at large has stood aside, lest their intervention might be a hindrance to the enactment of the reform. Now its principles are asserted, its mechanism approved, and its object accepted by Parliament, and we trust that the policy of *laissez-faire* will now give way to one of solicitude lest this great measure may prove to be as faulty as its predecessor the Act of 1858.

THE SCOTCH CONJOINT SCHEME.

In a recent issue we notified the fact that a conjoint scheme had been adopted by the Scotch Corporations. If the scheme is carried out as proposed, there cannot but be a doubt that the Colleges will suffer considerable pecuniary loss. There are to be three examinations instead of two, and as these are to be held at different periods—one after the first year of study, another after the second year, and the last at the end of the fourth year, students will have to take their entire course of study in Edinburgh, or at least in Scotland. The trips of southern students across the border will be materially lessened, and it is on this class of applicants for the diplomas of the Colleges that the Corporations have long looked for their sustenance. It is well known that the great bulk of students, after completing their University course, seek the diploma of the English College in preference to the Scotch, and that the seekers after the Scotch diplomas are, as a rule,

educated in every other part of the world but Scotland. Then, again, it will be seen that the fee for the double qualification is to be 25 guineas, or five guineas dearer than the double qualification of the University. In going to the Corporations the student will escape the study of Botany and Natural History, but an examination in these subjects is scarcely a sufficient deterrent to forego the higher dignity of a degree. The difference in the fees payable for a University degree and a Corporation diploma is not great enough to tempt men to take the lower for the higher, and if the examinations are of the same standard, the chances of the Colleges are still more remote. They can only hope to exist by levelling downwards, and this process the Government is apparently determined to resist. It does not, therefore, appear that the proposed conjoint scheme is any more favourable to the Corporations than the Government proposal—at least in Scotland, with the University system as it there exists. In England the Corporations would benefit by a conjoint board, because a University degree is both costly and difficult to obtain. The Government proposal, if we understand it correctly, is to allow the Corporations to examine in all but the final or practical subjects of the medical curriculum, and to charge fees for these examinations. It is a question whether the Scotch Corporations with the existing University system would not be better off than with a conjoint board as proposed. In any case, the passing of the Bill applying to Scotland the same regulations will work a manifest injustice to the Scotch Corporations and benefit unduly the English, which have never been in rivalry with the Universities of the northern division of the United Kingdom. In other words, the injustice of the Bill exists in applying like regulations to two countries whose institutions are in no way comparable. The Scotch Corporations have only to insist, as the Universities do, that a certain period of study must be completed in their schools to remove the opprobrium attached to them that they are the resting places of the waifs and strays of other schools and corporations, and this appears to be the most hopeful road out of the difficulty which now besets the Government proposal and the conjoint scheme.

THE COLLEGE MEETING.

On Monday afternoon the long-expected meeting of Fellows and Members of the Royal College of Surgeons of England was held in the theatre of the College, and was protracted to a length of nearly three hours. The President, Professor Marshall, F.R.S., occupied the chair, and was supported by nearly every member of the Council. The first part of the meeting was occupied with a discussion on the several alterations of Charter proposed by the Council, and already familiar to our readers, having been fully referred to in a recent issue of the *Medical Press*. Only one of these excited any amount of debate—that, namely, dealing with the arrangements of the Fellowship examination. To the proposal of the Council to empower alterations to be made by the resolution of the Council, in place of by bye-law, as at present, Mr. Tweedy moved an amendment to the effect that any such alteration of Charter would have the effect of relaxing the stringency of condi-

tions under which the Fellowship is now obtainable. In a somewhat lengthy but able speech, Mr. Tweedy defended the position he assumed, and instanced many facts to show the probability that the *prestige* of the Fellowship might be seriously imperilled if the proposition of the Council should be endorsed by the meeting. The principal argument lay in the past action of the Council itself, this having been consistently directed to removing obstacles afforded by requirements of age, practical experience, and educational qualification on the part of candidates for the diploma. After a long and animated discussion, however, the alteration recommended by the Council was carried, Mr. Tweedy's amendment having been defeated.

Following the acceptance of the various suggestions of the Council, the President invited other proposals from gentlemen present, but before doing so he took the precaution of pointing out clearly to the meeting that every resolution proposed would be forwarded to the Council merely as a *recommendation* to it, and that in itself, and until accepted by the Council, it could have no other value than this.

Mr. Paul Swain then proposed that, in the opinion of the meeting it was desirable that Fellows and Members should be invested with a larger share in the management of the College. That an annual meeting of Fellows and Members should henceforth be held, at which the Council should present a report, and that at such meeting the Fellows only present should elect the president for the ensuing year. All these proposals were ultimately carried, the last clause exciting very considerable discussion, Dr. Colwin especially insisting that Members as well as Fellows should unite in electing their president. A proposition by Mr. Forest that a special indemnity fund for reimbursing members who are put to expense in defending themselves against unqualified practitioners, should be created by Charter, was not carried.

Finally, Mr. Hickman, in a long but conclusive speech, moved that the Council should be requested to enter into negotiation with the Royal College of Physicians of London with a view to combining with it to form a single great College of Medicine, to be empowered to grant to its Licentiates the degrees of M.D. and M.S. Mr. Hickman certainly based his proposal on strong grounds, and the arguments he employed were of so convincing a nature that his "recommendation" was carried by a majority of six votes. This, and a vote of thanks to Mr. Marshall, who, throughout a somewhat excited meeting, preserved the most impartial attitude in the chair, closed the proceedings. The result of the gathering will, of course, depend on the spirit in which the Council listens to the recommendations that have been made to it; and until the effect produced by them is known it would be idle to speculate on future events. The meeting was by no means a large one, and was mainly composed of senior Fellows and Members of the College.

STILL another remedy for that intractable complaint the vomiting of pregnancy, is just put forward in our German contemporaries by Dr. Mial, who says that 0·3 or 0·5 grammes doses of sulpho-carbolate of soda dissolved in water never leave the physician in the lurch.

Notes on Current Topics.

Weldon v. Winslow.

BUT one termination could have been foreseen to the action brought against Dr. Forbes Winslow by Mrs. Weldon, and which ended on Wednesday last in the non-suiting of the plaintiff. The nature of the charges made by Mrs. Weldon was in itself an assurance of failure to substantiate them, and had we not the lady's own explanation of her intentions in bringing the action it would be difficult to understand why anyone should elect to risk anything on so flimsy a pretence. Mrs. Weldon, however, has but one principal aim in view, and that is to excite public attention to her imagined wrongs in being some years ago certified as a lunatic. As a remote object, also, the amendment of the lunacy laws is included in Mrs. Weldon's reform programme, one step in the fulfilment of which was made by her recent appearance in a court of law. We cannot help feeling, and all reasonable beings will agree with us, that it is a great hardship to medical men which enables persons of Mrs. Weldon's stamp to pester them with the annoyance of such charges as that which Dr. Winslow has had to rebut; and although the instances of improper certification are numerically the smallest possible, still, because the law permits it, any member of the medical profession who has signed an order of committal may find himself called upon to undergo the nuisance of a public examination by the patient he has already declared to be mad. This certainly is as much in need of amendment as the law to which the learned judge in his remarks to Mrs. Weldon referred. It may fairly be questioned whether Baron Huddleston did not place the facts too prominently forward in his vehement declaration that "It is somewhat startling—it is positively shocking—that a pauper, or, as Mrs. Weldon puts it, a crossing-sweeper, should make a statement, and then two medical men, who never had a day's practice in their lives, and would for a small sum of money grant their certificates, may do so, and that person may be lodged in a private lunatic asylum, and that this order and this statement and these certificates are a perfect answer to any action." Mrs. Weldon may indeed congratulate herself on obtaining such an expression of opinion from a judge, but to medical readers it will sound as little more than a pitiful reflection of the vulgar mistrust and deprecation of medical men, against which Sir Andrew Clark has recently raised his eloquent voice. The layman's view of the lunacy question must necessarily be narrow-minded and distorted, being as it is founded mainly on the information afforded by agitation-mongers, who have for an object the bringing of all lunatics under State control. From the Bench, however, we are accustomed to expect a moderation and reserve which would be unlooked for in the fanatic; but Mr. Baron Huddleston's implied mistrust of medical men, is at once undeserved, and, in our opinion, uncalled for. Should this case lead to such amendments in the Lunacy Act as are in reality required, then none will hail them more readily than the unfortunate doctors, who, as they are at present, constitute the worst victims under them.

The Question of Confidence in Doctors.

THE trial of the case *Page v. Harrison*, in which Dr. Page, of Birmingham, sued the husband of one of his patients for alandering him by accusing him of improper intimacy with the patient in question, was last week settled by a verdict in favour of Dr. Page, with damages £150. We have no desire to follow the details of this unfortunate episode; but it may be accepted as one more illustration of the truth that medical men can never be too carefully circumspect in their relations with female patients, and especially when circumstances may have arisen, of whatever kind, to suggest more than usual caution. The publication of the case, however, has had the effect of raising a discussion in the *Standard* on the question of "Women and Doctors," but which is unremarkable except for the very curious letter which originated it. This, purporting to be from "A Young Wife," accused medical men of intruding on the confidences which ought to exist between husband and wife alone, and consistently ended with the suggestion that women should be attended only by women doctors. The charge which "A Young Wife" prefers is, it does not need to be said, unfounded, nor that medical men, as often as they can without injury to their patients, purposely avoid discussion of details that might seem unbecoming to "Young Wife." When, however, safety to life and health demand that the medical attendant must obtain information which he can only get by means of questions that would come more appropriately from a husband, then stern duty commands the proceeding; but to call this an unjustifiable intrusion or the marital relations is as cruel as it is ridiculous. Moreover, after years of opportunity, the number of women entering the medical profession shows no signs of ever increasing beyond a phenomenal few, so that the female sex can never be in a position to trust to female aid alone in illness; and altogether the subject is one which admits of no defence or justification as a subject of newspaper discussion.

The Students of the Cork College.

THE authorities of the College have found it necessary to deal with several of the students, and accordingly summoned them before the Council to explain their action during the late election, in reference to certain letters which appeared in the newspapers, and to a meeting held condemnatory of the institution. After considering the matter, the authorities on Tuesday last sentenced the principal ringleaders to various punishments, and inflicted fines varying from £30 to £1. The chairman of the said meeting, besides forfeiting his College fees, has been rusticated for one year and a-half, and Mr. Hennessy, a senior scholar, was fined £30, the balance due on his scholarship. Without expressing any opinion whatever upon the course pursued by these very foolish young persons, we must support the collegiate authorities in their efforts to maintain its discipline. No educational institution which is expected to maintain any control over its *alumni* could permit newspaper abuse and extra-academic declamation of this sort. We shall not be sorry if this act of the College authorities deprives the profession of the credit of numbering these young gentlemen amongst its members.

They seem to us better fitted for the benches of the House of Commons "below the gangway" than for the practice of a calmly scientific profession.

The Irish Graduates' Association.

THE annual St. Patrick's Day *r union* of the Association took place on the 17th inst. at the Holborn Restaurant, the chair being occupied by the President, Professor Yeo. There were also present as guests, Sir Andrew Clark, Sir J. Lister, Dr. George Johnson, President of the Medico-Chirurgical Society, and, amongst the members, Sir William MacCormac, Mr. Stokes, of Dublin, the President-elect, Dr. Jacob, President of the Irish Medical Association, and many other distinguished Irish graduates. The dinner was in all respects admirable, and the toasts, being commendably limited to four, were drunk with enthusiasm.

The Association is a useful organisation for the promotion of social intercourse between Irish graduates, but, as a body representative of professional opinion, it is open to much improvement, and, under the presidency of Mr. Stokes, we hope to see reforms introduced. The Irish graduates are represented by the Medical Register as nearly 4,000, and this, we believe, is by a long distance an under-estimate of their number. As an independent organisation, bound together by national sentiment, the Association might aspire to be something much better than a dinner club, and, to give it a higher scope, certain reforms of administration are necessary. It ought not to be a hanger-on to the skirts of any other professional organisation, but should have an individuality of its own, and should perform the work which lies before it in England in some such manner and with as much vigour as the Irish Medical Association fulfils its functions in Ireland.

Amateur Cremating.

DR. PRICE, the *soi-disant* Welsh Druid, who was tried and acquitted of having endeavoured illegally and indecently to cremate the body of his illegitimate child, has at last succeeded in accomplishing his object. On Friday last he fixed three hurdles on a hill within his own private grounds, then had half a ton of coals piled within the triangle thus formed, and upon a pair of large iron gates he placed a box containing the body of the child, wrapped in napkins. Petroleum was thrown over the coals, and this served to make the pile a mass of fire as soon as ignition took place. The Druid, who is said to be 84 years of age, with a large shawl thrown over his shoulders, was present during the process, and chanted a Druidical dirge.

By the will of the Baroness Lionel de Rothschild, recently deceased, the London Hospital and the Evelina Hospital each receive a legacy of £10,000; the West London Hospital and the Jews Hospital £3,000 each; the Metropolitan Free Hospital and the German Hospital £2,000 each; the Buckinghamshire Infirmary, Margate Sea-Bathing Infirmary, the Hospital for Incurables, and Earlswood Asylum £1,000 each; and St. George's Hospital £500.

The Patent Medicine Bill.

THE following is a summary of the Bill introduced into the House of Commons by Mr. Warton, the second reading of which is fixed for to-day:—Whereas patent medicines containing poison have caused sickness and death: Be it enacted, &c.—1. From Jan. 1, 1885, any person claiming to be a proprietor of any patent medicine, and any vendor or purchaser of any patent medicine, may require same to be analysed by the British Pharmaceutical Society. 2. If the Society find that any patent medicine contains a poison, as in Schedule A. of the Pharmacy Act, then the Society may by resolution declare that such patent medicine contains poison, and shall submit the said resolution for the approval of the Privy Council, and if such approval be given, then on the expiration of one month the patent medicine named in such resolution shall be deemed to be a poison. 3. If the Society find that any patent medicine does not contain poison, the Society may by resolution so declare, and on the expiration of one month the patent medicine named in such resolution shall be deemed to be free from poison, and any proprietor or vendor thereof may label the box, bottle, vessel, wrapper, or cover in which such patent medicine is contained with the words "free from poison." 4. Any patent medicine shall, unless and until the said Society have analysed the same, be deemed to be a poison. 5. This Act shall not extend to Ireland.

Death of Dr. Hall Davis.

DR. J. HALL DAVIS, late obstetric physician to the Middlesex Hospital, died suddenly on Wednesday last week, at 2 a.m. Owing to declining health, Dr. Hall had resigned his post at the hospital just a week before his decease, but it is only very recently that he has been incapacitated from the active pursuit of his profession. In January of the present year he suffered from a slight attack of apoplexy, the effects of which, however, entirely passed off in a few days. Since then he has not felt so strong as formerly, and to this fact his resignation is attributable. A very general feeling of regret will be experienced at the loss thus occasioned to the profession, and universal sympathy will be extended to the relatives of the deceased.

ON Wednesday last, Mr. Gibson, M.P., gave notice to ask for the production and circulation amongst hon. members of the amended memorandum relative to the Indian Medical Service.

THE highest annual death-rates from diseases of the zymotic class in the large towns last week were—From whooping-cough, 1·7 in Newcastle-upon-Tyne, 1·5 in London, and 1·4 in Bolton; from measles, 5·1 in Oldham, 3·9 in Portsmouth, and 2·0 in Nottingham; from scarlet fever, 2·1 in Newcastle-upon-Tyne, 1·9 in Leeds, and 1·6 in Sheffield; and from "fever," 1·4 in Blackburn, 1·2 in Hull, and 1·1 in Birkenhead. The 28 deaths from diphtheria included 14 in London, 2 in Salford, and 2 in Leeds. Small-pox caused 11 deaths in London, 5 in Glasgow, 3 in Edinburgh, 2 in Liverpool, 2 in Sunderland, 1 in Sheffield, and 1 in Newcastle-upon-Tyne.

British Medical Association.

THE fifty-second annual meeting of the British Medical Association is fixed to take place at Belfast on July 29th next, and three succeeding days, under Dr. James Cuming, of Belfast, the President-elect. Sir Andrew Clark has consented to deliver the address on medicine, and that on physiology will be undertaken by Professor Redfern, while Dr. G. H. Kidd will give the address in obstetrics.

Decreased Mortality and its Causes.

IN a very admirable statistical paper on "The Recent Decline of the English Death-rate considered in connection with the Causes of Death," read before the Statistical Society on Tuesday, the 18th inst., the author, Dr. G. B. Longstaff, has collected a great amount of very valuable information relating to recent declines in the national death-rate. The most marked fact brought out in it is that zymotic diseases and phthisis account for far fewer deaths proportionately than was the case in the pre-sanitation era; and it is a legitimate conclusion, therefore, that the result of that awakening to the importance of hygiene which has occurred in late years has been to add materially to the life of the people. Such a result would of course be anticipated; but it is, nevertheless, most gratifying to find one's hopes and expectations so irrefutably confirmed as they are by the figures in question. Dr. Longstaff, however, is of opinion that an increase is taking place in the number of deaths arising from cancer, and he shows, also, that the improvement observed in the class of zymotics as a whole has not been demonstrated in the cases of measles and whooping-cough. In general, it has been found that much more accuracy now obtains than formerly in classifying the causes of death on the part of medical attendants, who appear, judging from the returns, to exhibit both greater skill in diagnosis and higher care in certifying than was accounted essential in times gone by. Altogether the amount of information collected by Dr. Longstaff is of the most complete and valuable description, and his paper is a solid and permanently useful contribution to health statistics.

MAGNIFICENT bequests have just fallen to the Glasgow and Leicester Infirmarys. Mr. James White, late of Overtown, Glasgow, has bequeathed £10,000 to be divided equally between the Glasgow Royal Infirmary and the Glasgow Western Infirmary; and Mr. Joseph Pool, late of Leicester, has left between £10,000 and £15,000 to the Leicester Infirmary.

IN the principal foreign cities the rates of mortality per 1,000 of the various populations were, according to the latest official returns, as follow:—Calcutta 29, Bombay 24, Madras 49, Paris 24, Geneva 38, Brussels 24, Amsterdam 28, Rotterdam 26, The Hague 26, Copenhagen 23, Stockholm 26, Christiania 21, St. Petersburg 42, Berlin 23, Hamburg 24, Dresden 30, Breslau 35, Munich 35, Vienna 30, Prague 39, Buda-Pesth 27, Trieste 46, Rome 39, Turin 34, Venice 37, Lisbon 35, New York 27, Brooklyn 20, Philadelphia 21, and Baltimore 22.

The Army Surgeons wounded at El Teb.

THE two medical officers whose names appear in the list of casualties in the recent Soudan engagement were Surgeon Prendergast, of the Army Medical Department, and Surgeon H. E. F. Cross, of the Royal Navy. Mr. Prendergast joined the service only quite recently. He was a Grey's man and an M.D. of the Queen's University. He was speared in the chest as he stayed behind to look after the wounded, and was with difficulty saved by two soldiers. Mr. Cross is a naval surgeon of some years standing. He was wounded in the forehead by a bullet. Both are happily doing well.

Proposed Monument to Marion Sims.

A COMMITTEE has been formed, representing the profession in various parts of America, to obtain funds for the erection of a monument to the late Dr. Sims in New York. Dr. Fordyce Barker is the chairman, and Dr. George F. Shrady is secretary.

The Prison Surgeons and the Prisons Board.

WE are pleased to learn, as we go to press, that the suit instituted by the Irish Medical Association in vindication of the rights of Irish prison surgeons has resulted in a decision in their favour, and against the General Prisons Board. The facts were these:—The surgeon to the Galway prison was summoned to give evidence before the Royal Commission on Irish Prisons, and, as in duty bound, he recommended that Dr. Rice should be employed as his substitute during his absence, but he had no communication with Dr. Rice, and did not in fact know whether the prison authorities would act on the recommendation or appoint someone else. As a matter of fact, they got the official approval of the General Board, in Dublin, and then intimated to Dr. Rice that he was to attend and perform the duty. He did so, but when he asked for his fees he was refused; and referred to the absent surgeon. He consulted the Irish Medical Association, and on their advice, sued the Prisons Board. At the Quarter Sessions the claim was refused, and the Association took the case on to the Assizes, where the decree of the lower court was reversed, and the Prisons Board ordered to pay.

The Irish Poor-law Superannuation Bill.

WE regret to believe that the chances of this Bill becoming law this session are indefinitely remote. The desire of Mr. Herbert Gladstone, of the Chief Secretary, of the Government, and of all parties in the House that it should become law is not less earnest than heretofore, but the difficulties of legislation are every day becoming greater, and the power of the half-dozen Nationalist obstructives who oppose the Bill is therefore greater. So chaotic is the condition of Parliament at present that no measure can advance a single step unless it is unopposed or is of sufficient importance to be made a battle-ground of parties in the House. A fourth of each sitting is occupied by questions which are not intended to elicit information, but to annoy Ministers; a half in the debating questions raised on the motion to go into committee of supply, questions which have neither beginning nor end, except to ventilate the views of movers; and the remaining fourth of the sitting is employed in voting—at cock-crow—enormous quantities of public money without any adequate consideration. The Irish Office has not yet advanced even

one of its Bills a stage, and has been obliged to take its Sunday Closing Bill off the notice paper in despair of getting it discussed within any reasonable period, and a few days ago the Home Secretary, speaking of lunacy legislation, informed the House that the Government would be glad to take up the subject "if they had any power to pass any Bill."

Meanwhile, whenever a day is set aside for private business, it is not uncommon for Mr. Biggar, or some of that ilk, to count out the House. In fact, legislation has come nearly to a standstill, and there is no hope for any secondary Bill unless Government pleases to apply itself in earnest to the business of the country.

VISCOUNT MONCK, Lord Lieutenant for the a County Dublin, has appointed Dr. Lyons, M.P., to be Deputy-Lieutenant for the County.

SIR JOSEPH LISTER, Bart., will take the chair at the Parkes Museum to-morrow evening (Thursday), when Mr. Watson Cheyne, F.R.C.S., will give a demonstration for all the principal types of micro-organisms.

WE understand that H.R.H. the Princess Louise, Marchioness of Lorne, has consented to open the new wing of St. Mary's Hospital, Paddington, on the 6th of May, on which occasion she will also distribute the prizes to the hospital students.

DR. KENDAL FRANKS, Surgeon to the Adelaide Hospital, Dublin, has been appointed medical adviser to the *employés* of the Bank of Ireland and their families, in room of Dr. Rutherford Kirkpatrick, resigned. The appointment is worth about £250 a year, and we understand that an arrangement has been made by which the attendance on the wives of the *employé* will be given by an obstetric physician.

WE are asked by the committee of the West End Hospital for Diseases of the Nervous System, Paralysis, and Epilepsy, to announce that Mr. Proctor, the hon. secretary, has felt obliged to tender his resignation in consequence of not being able to give the necessary time to the increased duties of the office. The committee have, however, elected this gentleman to the post of treasurer to the hospital, with a seat at the committee of management, as a mark of their esteem and appreciation of his services.

THE deaths registered last week in the principal large towns of the United Kingdom corresponded to an annual rate of 22.6 per 1,000 of their aggregate population. The death-rates in the several towns were:—Plymouth 15; Cardiff 16; Brighton, Derby 17; Norwich, Bradford, Sheffield 19; Portsmouth 20; Birmingham, Huddersfield, London, Edinburgh, Leicester, Nottingham 21; Liverpool 22; Hull, Glasgow, Bristol, Sunderland 23; Newcastle-on-Tyne 24; Preston, Halifax, Bolton, Oldham 25; Wolverhampton 26; Dublin, Salford 27; Blackburn, Leeds, Birkenhead 29; Manchester 30.

Scotland.

[FROM OUR NORTHERN CORRESPONDENTS.]

HEALTH OF EDINBURGH.—For the week ending with Saturday, the 15th inst., the mortality in Edinburgh was 97, and the death-rate 20 per 1,000. There were 20 deaths under 1 year, and 24 above 60, of which 6 deaths were above 80 years. Diseases of the chest accounted for 45 deaths, and zymotic causes for 15, of which 3 were due to fever, 2 to diphtheria, 3 to scarlatina, and 8 to measles, the intimations of these diseases for the week being 11, 7, 32, and 105.

MORTALITY IN GLASGOW.—The deaths in Glasgow for the week ending with Saturday, the 15th inst., were at the rate of 23 per 1,000 per annum of the population, as compared with 27 in the previous week, and 34, 25, and 30 in the corresponding periods of 1883, 1882, and 1881 respectively.

EPIDEMIC OF MEASLES AT DUNTOCHER.—For some weeks past a serious epidemic of measles has been raging in this village, and still continues. The public schools have been closed. The disease is of a very bad type, especially amongst the young children, and has proved fatal in a great many cases.

SEWER GAS.—A few years ago prominent members of the medical profession in Glasgow, gentlemen of much appearance in public, had sewer gas on the brain. This was bad enough, but when associated with "uterus on the brain" it is sufficiently alarming in all conscience. The "Philosophical Society of Glasgow" is a society chiefly composed of the well-to-do tradesmen of the city, and it forms an excellent arena for forensic and learned displays by pushing medical men. It is well taken advantage of for this purpose. At a meeting of this society, held on the 19th inst., Dr. Robert Bell, physician to the Glasgow Institution for Diseases of Women, who, by the way, is nothing if not emphatic in his denunciation of wickedness (methinks, indeed, he "protests too much"), read a paper on "House Sanitation," a subject to which Dr. Bell has consecrated some paper and ink, as his wonderful pamphlet "On Diphtheria" shows. In the course of the paper Dr. Bell expressed the opinion that dishonest plumbers and builders were frequently as guilty of manslaughter as were the wretches who from time to time were convicted of that crime at the bar of justice. He referred to two cases of bad drainage met with in his own experience. In one of the cases four children had been attacked with typhoid fever, while in the other case a number of children had been attacked with diphtheria, as a consequence of defective drainage. It was appalling to contemplate how many valuable lives might have been sacrificed to the avarice of tradesmen in the construction of defective drains. As a protection against bad drains he suggested that the work should not be covered in until it had been inspected by a surveyor, and certified to be in perfect order. The pipes should also be examined periodically. He recommended that the surveyor should be appointed by Government, and that he should be independent of plumber or proprietor.—Dr. Eben Duncan gave it as his opinion that if sewage gas propagated fever at all, it did so in a very small degree. It was too frequently the case with medical men when they were called in to a case, and found there was a defect in the drainage of the house, that they considered that sufficient to account for the disease. That, he thought, was a false position for any man to take up.—We agree, so far, with Dr. Duncan. Much merited contempt is brought on ephemeral medical theories, in consequence of the abundance in the medical profession of under-educated hobby-hornical men who are incapable of seeing or reasoning beyond one phase of given questions. We do not agree with those who argue that those people should be let alone, and left to the

ultimate tribunal of public common sense, for public common sense is an infinitesimal quantity.

INFECTIOUS DISEASES IN EDINBURGH.—Dr. Littlejohn reported to the Town Council's Public Health Committee last week that at present there were 30 cases in the City Hospital, 64 in the Old Infirmary, and 20 in the Sick Children's Hospital—114 in all, as against 116 a fortnight ago. Of typhus fever there were 16 cases, typhoid 15, scarlet 62, measles 10, erysipelas 9, and chicken-pox 2.

INSPECTION OF MILKSHOPS.—The Edinburgh Town Council's Public Health Committee have instructed the medical officer for the city to communicate with the chief constable, with the view of obtaining a list of all persons selling milk, whether in dairies, or in shops along with other provisions, so as to allow of a complete sanitary inspection being made. Last week it was found necessary to close a dairy at Greenock in consequence of an outbreak of enteric fever among families supplied therefrom. On officially inspecting this dairy the medical officer found that, while the apartment in which the milk was kept was clean and tidy, the place where the milk vessels were washed was in close proximity to a large dung-hole, piggeries and stables—all so constructed and arranged as to keep the adjacent area, which was unpaved, saturated with excrementitious matters.

PUSHING BUSINESS WITH A VENGEANCE.—The following advertisement appears in the *Glasgow Herald* of the 22nd inst., and we have only to express the hope that it does not emanate from a medical man :—

SICK-ROOM COOKERY.—A Lesson in preparing food for invalids and making different kinds of poultices will be given in St. Andrew's Halls on Wednesday, 26th March, at 11 A.M. Admission, 1s.

TERCENTENARY GOSSIP.

SOME of our German professional guests will open their eyes when they learn that a professor in the University for a three months' course of fifty lectures draws from the students an income of over £2,000 per annum. And that a professor after fifteen or twenty years' enjoyment of such an income, can retire on the score of ill-health or advancing years on an annuity of two-thirds of that sum.

It would not be a very great tax on the professional staff of the University if they supplied from their own pockets the banquet for their distinguished guests. A small disbursement from their annual income would not affect their annuity which the Government and not their thrift provides.

THERE is to be a breakfast given to the distinguished visitors by the College of Surgeons, and a luncheon by the College of Physicians, out of the funds of the corporations. The colleges have certainly set a good example to the University which last year tried to strangle them out of existence.

A FEELING of sincere sorrow has been awakened both in Edinburgh and Glasgow at the unexpected death of Dr. Allen Thomson, in London, on Friday last, whither he had gone to reside on his retirement from active pursuits some three or four years since. Deceased was formerly Professor of the Institutes of Anatomy in Edinburgh University, a Graduate and an LL.D. of the same institution; and much regret is expressed that he was not spared to take part in the coming Tercentenary.

THERE is a feeling of disappointment among the students that they are to play a minor part in the Tercentenary celebration, and mass meetings are held at which the grievances of the students are loudly proclaimed. It has been

the hope of many undergraduates that they would receive these degrees along with honorary degrees to be conferred by the university, but this hope has been rudely pushed aside. It certainly seems a little unfair to men who have worked with a definite object to be deprived of the honourable ambition of receiving their degree on the three-hundredth birthday of their *alma mater*.

Literary Notes and Gossip.

THE French Academy of Medicine has just been the scene of an animated contest between candidates for the seat rendered vacant by the death of the late Professor Lasègue. The choice of the electors lay between MM. Sirey and Bouchard, and fell on the former, who received 48 votes out of 85.

Le Praticien announces that Mme. Broca has offered a prize of 1,500 francs, to be given by the Anthropological Society of Paris, for the best memoir on questions concerning human anatomy, comparative anatomy or physiology, bearing on anthropology. The first prize will be awarded in April next.

THE Edinburgh University Tercentenary celebration promises to be a very brilliant affair, and already intimations have been received to the effect that most of the important foreign Universities will be represented at it. A liberal dispensation of honorary degrees will be made, and nothing is seemingly wanting to ensure that the whole arrangements will be completely successful.

WE are certainly not rich in Tercentenary literature, for, besides the two bulky volumes of the Story of Edinburgh University by the Principal, the only other production which the occasion has produced is a pamphlet by Dr. F. Shenck on "The Celebration of the Tercentenary of the University of Edinburgh, and a humorous treatment of artes, scientiæ and gastronomia." A Tercentenary Album is talked of, which shall contain pen and ink portraits by Mr. Holl, A.R.S.A. of the several professors. Gossip has it that these sketches will be in the style of good-natured caricature, and will be both interesting and amusing.

MR. FRANCIS GALTON's offer of £500 in prizes to those British subjects, resident in the United Kingdom, who furnish the best Family Records, has already excited some attention. Competitors must send in before the 15th of next May. "The Record of Family Faculties," which he has published, will not only interest competitors but others, and the filling up of the forms might be made interesting to some, though there is a fear that it may degenerate into a game.

THE Investigation Committee has also published a "Life History Album," which is edited by Mr. Galton, and is designed to contain a chart of the owner's life, and to be a record of his biological experience. We can readily believe that such a record may be of considerable value, and, indeed, everyone knows how difficult it is to obtain any trustworthy medical history of our patients. We fear, however, that very few will be found to persevere in keeping such an elaborate diary as the committee propose.

AMONG the recent elections to examinerships at the University of Durham we note that of Dr. W. P. Mears, to be Examiner in Anatomy. As the author of a most useful and original treatise, entitled "Schematic Anatomy," Dr. Mears has already shown himself to be a successful teacher of the subject; and though it does not always follow that able instructors constitute good examiners, there can be little doubt that in this instance the reverse of this will occur.

A WELL-DESERVED honour has been paid to Physiology by the President of the French Republic, who, by decree dated March 12, 1884, has conferred the distinction of the Cross of the Legion of Honour on Dr. Reynaud, Professor of Physiology at the National Institute of Agriculture. Dr. Reynaud's services to science have been exceptionally considerable, and he has already been deemed worthy of being named Laureate of the Institute for his physiological works. His researches have

been both numerous and important, and include several on the subject of alimentation, and the nutritive value of blood as a food for animals.

THE *South African Medical Journal*, of which the first and second numbers have reached us, is an excellent attempt to supply the colony with a representative organ of professional opinion; and in these numbers the editor makes a most sensible statement of the rôle his paper is intended to fill, viz., that of being to the South African doctors what the leading journals in this country are to their readers. The ambition is not an unworthy one; and with unlimited energy, inexhaustible patience, and blind determination in face of obstacles, we do not doubt our *confrères* will slowly arouse an amount of enthusiasm sufficient to encourage him to a continuation of his literary endeavours.

THE first two volumes of the "Lessons on Experimental Chemistry," by Dr. Emerson Reynolds, of the Dublin University, the issue of which was noticed in our columns some few months since have been paid the high compliment of being translated into German and published by Winter, of Leipzig. This acknowledgement of the merits of the book, following upon the rapid sale of the English addition, must be very gratifying to the author, and is very creditable to the Irish School of Chemistry. Dr. Liebert, of Wiesbaden, is the translator, and he seems to have rendered the English version admirably, preserving the simplicity of language which has made the book so popular.

"WOMEN AND DOCTORS" forms the title of the newest craze in daily newspaper controversies; it originated in a letter contributed to the *Standard* by a "Young Wife," who most absurdly attacked the medical profession with presuming on the facilities their position gives to them for receiving what she terms "confidences" in respect to their health-states. It is not unlikely that every physician in extensive practice has among his patients a good many who suffer from the kind of hysteria exhibited by the writer of the letter referred to; and in their interest, as well as that of the profession, it would be a good thing if a little more general understanding of the real needs of professional attendance could be made quite clear.

LONDON is by no means singular in the possession of a miserable section of people whose homes form fit subject for graphic denunciation. We have had the same dismal story of squalor, drunkenness, and disease echoed from Birmingham, Dublin, Newcastle, Aberdeen, &c.; and among the most recent contributions to the literature of slum-ism is an able series of papers collected from the *Bristol Mercury*, to which they have been contributed serially by a "Special Commissioner." In these are presented pictures of life which scarcely differ in any degree from those familiar to every reader of the daily press, while they equally demonstrate the urgent call that exists for some sort of radical reform in the circumstances under which our poor manage to exist.

OF books announced as in the press may be mentioned:—New editions of Murchison's classical treatises on "The Continued Fevers of Great Britain," edited by Dr. Cayley, and "On Diseases of the Liver," edited by Dr. Brunton, F.R.S. A "System of Psychology," in 2 vols., by Dr. Greenleaf Thompson. "Outlines of Psychology," by Mr. James Sully, of Cambridge University. A "Manual of Histology," by Professor Purser, of the Institutes of Medicine, Trinity College, Dublin. A "Manual of Public Health," by Dr. Hime, Medical Officer of Health for Bradford; and a work by Surgeon-General Gordon, on Chinese Medicine. A translation by Professor Tyndall of Pasteur's, "Life and Labours" is also promised, and a translation from the German of Kolbe's Text-book of Inorganic Chemistry.

MR. C. E. JENNINGS has republished in a small volume his contributions on "Transfusion" (Baillière, Tindall, and Cox). He advocates, as most of our readers know, intravenous saline injections, and has devised another instrument for that purpose. As a former resident accoucheur at the London Hospital, we are astonished that he has not looked into Dr. Little's extremely valuable contributions to this subject, for except by the incidental mention of the name here and there, we might almost suppose he was ignorant of the great advances made by Dr. W. J. Little when physician to the London Hospital, and to his son when assistant surgeon to the

same charity. Mr. Jennings appends a bibliography of about a dozen pages, and here, also, the name of Little is conspicuous by its absence. He might easily look up the volumes of the London Hospital Reports if he finds any difficulty in laying his hand on the earlier contributions of Dr. Little.

THE conductors of that able publication "*The Annales des Maladies De l'Oreille, du Larynx et des Organes Connexes*," with a view to popularise it in English speaking countries, have appointed Dr. M. Mackenzie, of London, as a *collaborateur*, and, henceforth, contributors can have their articles published in that journal in English or French. In the specimen number to hand is an illustrated contribution on "*Hypertrophy of the Mucous Membrane of the Nose*," by the English editor and in the English language, the rest of the journal being entirely French. The paper gives a good explanation of the changes which take place in chronic catarrh of the mucous membrane covering the turbinated bones, and the author speaks strongly against operative interference except in cases of rare and severe character, and advises the frequent use of the nasal bougie, and of mild alkaline lotions.

THE first volume of "*A System of Obstetric Medicine and Surgery*," which has been in preparation for the last two or three years, by Drs. Robert and Fancourt Barnes, has just left the press, and promises, from a casual glance, to form a very complete text-book of modern views and operations in this branch of medicine. We have also received an imposing-looking and beautifully-illustrated folio "*Atlas of Female Pelvic Anatomy*," by Dr. Berry Hart, of Edinburgh. Among other new books for the present month may be mentioned two *Manuals of Physiology*, one by Professor Yeo, the other by Professor Lowne. "*The Gold-headed Cane*," by Dr. Munk, Harveian Librarian to the London College of Physicians, is also an interesting production. This celebrated cane, which now occupies a conspicuous position under a glass case at the College, could, from its past associations, tell many interesting anecdotes of its various owners in ancient times; but as, like them, it is speechless, Dr. Munk has endeavoured to endow it with imaginary life, and thereby creative of fruitful retrospective thought. We defer criticism of these works to a future occasion.

MR. RUSHTON PARKER, Professor of Surgery in University College, Liverpool, has reprinted his "*Series of Twelve Bone and Joint Cases*" in pamphlet form. It contains reports of five cases of joint affection, in which the leading feature of treatment has been the maintenance of absolute immobility of the joint by means of splints, and the avoidance of pressure on the two opposing articular surfaces by means of Thomas's knee splints, by the aid of which the patient is in many cases enabled to walk about or continue his employment whilst under treatment, the whole weight of the trunk and even of the leg, being supported by the splint, which is fashioned below into the form of a patten. As the readers of this journal have learned the nature of these invaluable splints from Mr. Thomas's own writings, no further description is here necessary. The remaining seven are cases in which a similar or slightly modified form of splint was used for fractures accidentally produced, or made intentionally for the purpose of remedying deformities of the lower limbs. The whole form an interesting series of illustrations of what we venture to call the Liverpool system of mechanical treatment of bone and joint cases, of which Mr. Parker is known to be an enthusiastic advocate.

NEW BOOKS AND NEW EDITIONS.—The following have been received for review since the publication of our last list, February 27:—*The Medical Register for 1884*. *The Dentist's Register for 1884*. *A System of Obstetric Medicine and Surgery*, by Drs. Robert and Fancourt Barnes. Vol. I. *An Atlas of the Bones and Ligaments of the Human Body*, by Dr. Witkowski; text Translated, by A. T. Norton, F.R.C.S. *The Homes of the Poor*. *A Treatise on the Chemical Constitution of the Brain*, by J. L. W. Thudichum, M.D., F.R.C.P. *Memorials of J. Flint South*, F.R.C.S., by C. L. Felton, M.A. *Bacteria and the Germ Theory of Disease*, by H. Gradle, M.D. *Aids to Physiology* (4th edit.), by B. Thompson Lowne, F.R.C.S. *Aids to Botany* (2nd edit.), by C. Armand Semple, M.D. *A Manual of Physiology*, by Gerald F. Yeo, M.D. The

Plumber and Sanitary Houses, by S. S. Hellyer (3rd edit.). *The Gold Headed Cane*, edited by W. Munk, M.D. *Aids to Obstetrics*, by Samuel Nall, M.B. Cantab. "*Post Nasal Catarrh*," by Edward Woakes, M.D. "*Injuries and Diseases of the Jaws*" (3rd edition), by Christopher Heath, F.R.C.S.

Medico-Parliamentary.

HOUSE OF LORDS.—THURSDAY, MARCH 20.

THE MEDICAL ACT AMENDMENT BILL.

ON the motion of Lord CARLINGFORD that the House go into Committee on this Bill,

LORD BALFOUR informed the Government that the Universities of Scotland did not look with any more favour on the provisions of the present Bill than of the Bill of last year. The provisions to which they chiefly objected were those which would, in their opinion, lower the general standard of medical education in Scotland. The Universities believed that if the Bill passed in its present form all candidates upon their degrees would have to undergo a double examination. A man who desired to practise as a doctor, and had obtained a University degree, would be debarred from entering upon the actual duties of his profession unless he underwent the qualifying examination required by the Bill, which would admit him to the Register. Such a provision would be unworkable in practice and inexpedient in theory. With regard to the Constitution, he did not think there would be any objection to the Universities having eight representatives on the Medical Board, as provided in the Bill of last year, and to the representation of the Corporations being increased from three to five; but he did think the allocation would not be acceptable.

After a few remarks from the Duke of RICHMOND,

LORD CARLINGFORD said that the allocation was a matter beset with many difficulties. One had to steer through shoals and quicksands in all directions, created by the jealousies or interests of a large number of bodies consisting of the Universities on the one hand and the Medical Corporations on the other; also by the jealousies among themselves of the Universities and the Medical Corporations respectively. He was not wedded to the proposal in the Bill, but was willing to consider any more satisfactory means of allocating the representatives on the Board which would attain the object contemplated. He should be greatly disappointed if the Bill did not pass during this Session.

Their Lordships then went into Committee on the Bill.

ON Clause 9, Lord CARLINGFORD moved an amendment, changing the constitution of the Irish Medical Board. He proposed to put the Irish College of Physicians upon an equality with the Irish College of Surgeons.

The Clause, as amended, was agreed to, as were also the remaining provisions of the Bill.

HOUSE OF COMMONS.—FRIDAY, MARCH 21.

THE LUNACY LAWS.

MR. W. CORBETT asked the Home Secretary whether his attention had been called to the case of Weldon v. Winalow, in which Mr. Baron Huddleston, on giving judgment, had commented on the astonishing fact that anybody might be shut up in a private lunatic asylum with an order signed by two medical men, and also whether other cases of a similar and worse kind had not been reported.

SIR W. HARCOURT said the question was one of great interest and importance. The matter had, however, been carefully investigated by a committee in 1878, especially on the point whether a possibility existed of persons being unduly deprived of liberty by means of a false allegation. That committee had agreed that allegations of *mala fides* had not been substantiated, and that had been true, as far as he was aware, since. He was not prepared to say that the present system required no amendment, and he would be very glad to make a change in the law on this and on many other subjects, but was sorry to say that it was absolutely impossible for the Government or, as far as he could see, anybody else, to pass any bill on any subject (cheers and laughter).

Mr. MACIVER asked why the Government did not abandon some of the many controversial matters and proceed with more useful ones?

Sir W. HARCOURT had not been able to discover what was a subject which was not a controversial matter (laughter).

HOUSE OF COMMONS.—MONDAY, MARCH 24th.

THE INDIAN MEDICAL SERVICE.

In reply to Mr. Gibson, Mr. J. K. CROSS stated that he would lay the amended Memorandum relative to the Indian Medical Service, together with those which preceded it, on the table. The last Memorandum made no change in the conditions of service, but merely elucidated certain points, regarding which misapprehension is alleged, although these points are identically the same as have been continuously notified since the year 1876.

Obituary.

DR. ALLEN THOMSON, F.R.S.

ONE of the most profound anatomists the present century has given birth to passed away on Friday last in the person of Dr. Allen Thomson. Deceased retired from the active discharge of professional work some few years since, from which time to his death, which occurred somewhat unexpectedly, he resided in Palace Gardens, Kensington. For eighteen years he represented the University of Glasgow in the General Medical Council, his career in that august body being marked by that courteousness of manner to friend and opponent alike which won for him throughout his professional life such a host of friends. Few will be able to contemplate his death without feelings of regret when they remember that nobility and thorough honesty of character which never shone more brightly than when endeavouring to remedy abuses and to hasten the many educational reforms which he saw looming in the near future. Dr. Thomson was the author of many literary contributions, but his name will be best remembered in this direction as joint Editor of Quain's classical work on Anatomy. His professional career commenced in 1830, when he obtained the M.D. Ed. In 1832 he was elected to the Fellowship of the Edinburgh College of Surgeons, and the University of Oxford conferred upon him the honorary degree of D.C.L., and the Universities of Edinburgh and Glasgow the LL.D. He was also honoured with the blue ribbon of Science, the Fellowship of the Royal Society, and occupied the Chair of Anatomy in the University of Glasgow from 1848 until his retirement in 1877.

DR. CHARLES WILSON, OF EDINBURGH.

At the ripe age of 80, we are called upon to announce the death of Dr. Charles Wilson, which took place at his residence, Dalrymple Crescent, Edinburgh, on Wednesday last. Deceased was educated for the medical profession at Edinburgh University, proceeding afterwards to Paris to complete his studies. In 1828 he commenced practice in Kelso, his native town, where he remained till 1854. He was the first secretary of the Tweedside Physical and Antiquarian Society, and exerted himself greatly in establishing its museum. For a long period he also filled the office of secretary of the Border Medical Society, and was held in the highest esteem by the members, who presented him with a testimonial, to which he attached great value. On giving up practice in Kelso, Dr. Wilson proceeded to Vienna, and subsequently settled in Edinburgh, where he continued to practise until he retired in 1864. Meanwhile, by his energy he succeeded in founding the Hospital for Sick Children, which has since become a Royal institution, with an excellent staff and 84 beds. He was also for several years honorary librarian to the Royal College of Physicians. Since his retirement from practice, Dr. Wilson, who was a great linguist, devoted himself exclusively to literary studies, of which he was always very fond. Dr. Wilson received the M.D. Edin. in 1827. He became a F.R.C.P. Ed. in 1855, and was elected Corresponding Fellow to many foreign learned societies. In 1855 he published a work on the "Pathology of Drunkenness," and among his contributions to medical journals, which attracted considerable attention, were articles on "Croup," and on the "History of Medicine in Spain." Both in public and private life the deceased was justly esteemed.

SURGEON-GENERAL FURLONG.

WE regret to announce the death of Surgeon-General Furlong, recently Principal Medical Officer of the Army Medical Department in Ireland. Dr. Furlong had been transferred from Halifax, Nova Scotia, where he served for a long period, to Ireland, and, on his retirement from the Service last year he took up his residence at Llandysall, in South Wales, where, unhappily, he shortly showed symptoms of thoracic aneurism, from which, after a few months, his death has resulted. Dr. Furlong was much esteemed, both by his superiors in the Service, who had entrusted him with very responsible duties, and also by the subalterns of the Department whom it was his function to control.

International Health Exhibition.—The great interest manifested in the forthcoming Exhibition is shown by the fact that application has been made, by British exhibitors alone, for space five times as great as that actually at the disposal of the Executive Council. Information has recently been received that the French Government has appointed a Commission; and Italy—owing in a great measure to the individual exertions of a member of the Executive Council—will, it is hoped, take an active part.

Notices to Correspondents.

THE HOSPITALS ASSOCIATION.

WE are asked to announce that it has been arranged that the evening meetings of the Association shall be held at the rooms of the Medical Society of London, Cavendish Square. The first will take place this evening (Wednesday), when Mr. William J. Nixon, house governor of the London Hospital, will read a paper, "On Difficulties associated with the Administration of the Out-patient Department, and how best to deal with them." Sir Andrew Clark, Bart., will preside.

KILLED BEFORE HIS TIME.—In its attempts—commendable in themselves—to be first in the announcement of news within and without the profession, our contemporary the *Lancet* sometimes falls into very serious errors. For instance, in its issue last week, March 22nd, it speaks of the death of Surgeon-General Archer as occurring on the 27th instant. Many a man has before read his own obituary notice, but, unfortunately, in the present instance it is not possible, as we regret to announce that Surgeon-General Archer, with whom we had the pleasure of personal acquaintance, is no longer in the flesh, albeit the 27th has not yet arrived.

A FACETIOUS LEGACY FOR MEDICAL SERVICES.

THE *Canadian Practitioner* reports the death of an old lady who had reached her four-score and ten. On opening her last will and testament it was found that she had bequeathed to her physician, "to whose enlightened care and wise prescriptions I owe my long life, all that is contained in an old oak chest in my boudoir, the key to which will be found under the mattress of my bed." One can more readily imagine than describe the feelings of the said enlightened and wise physician when he discovered, instead of the fortune, all the drugs and potions, still intact, which he had prescribed for the old lady for many years back.

A SATIRE UPON INTERN APPOINTMENTS.

MUCH dissatisfaction having been occasioned among the students at Queen's College, Birmingham, at the appointment of an outsider to the office of house physician over their heads, when some of their number already possessed higher qualifications than the person put into the post, the following satirical document was placarded on the walls last week, and created considerable amusement at the expense of the authorities:—

NOTICE TO STUDENTS, ABOUT TO QUALIFY. QUITS' HOSPITAL.

WE, the Committee of the Quits Hospital, have noticed with regret, the immense strides in intelligence and industry taken by our students during the last three years, and the corresponding tendency to take new-fangled and higher qualifications to the detriment of those which our ancestors of several centuries since justly respected and revered.

Knowing full well that this course of events must lead to the cultivation of your minds to a dangerous and alarming extent, we have felt it necessary, in the exercise of our paternal care over you, to pass the following resolution at a meeting of the committee on the 25th ultimo. We would warn all students of the dire effects of educational over-pressure; and, to give force to our opinion we hereby decree that the appointments of this Hospital shall in future be granted only to such of our students as shall exhibit the following esteemed qualification—L.F.P.S. Glas., L.S.A. Lond., L.A.H. Dub., "Double," Edin. The possession of any (presumably) higher diplomas in addition to these will be visited with our displeasure and will mark the candidate as dangerous; yet one or more failures to attain thereto will proportionately enhance his chance of election.

In addition we now place all Scotch degrees in the above favoured category, and also express our determination, should there be a lack of suitable candidates from our own School of Medicine (owing to an extraordinary lack of appreciation of our efforts on your part) for the

appointment, to elect *strangers* with the aforesaid objectionable higher qualifications rather than give you any encouragement to disobey our express command.

Feeling that we are acting for the best interests of the School of Medicine, our patients and ourselves, we are now fully rewarded for the trouble we have taken, and cry

QUITS.

By order.

GUY'S.—*Portio mollis* is the name given to the auditory nerve by those anatomists who take it as a branch of the seventh pair of cerebral nerves, instead of considering it as a distinct (eighth) pair.

MR. FENWICK.—The surgeon first called to the case was undoubtedly right in at once performing the operation, seeing that it was immediately necessary in the interests of the patient. By subsequently communicating with the family attendant, and offering to transfer the after-treatment, he did all that could possibly be expected; and we entirely fail to see in what respect he can have been supposed to act improperly "towards a *confère*."

VALEDICTORY ADVERTISING.

NOT long since we had occasion to animadvert upon a circular issued by a hospital surgeon—when emigrating to another country—to his own and other people's patients, in which he made it a personal favour that the person addressed should "call in" the practitioner recommended by him. Our attention is now called to a similar case, and we are asked our opinion as to the following document, circulated widely in Clonmel by a gentleman who is leaving that district:—

[PRIVATE.]

MY DEAR MR. ———, Owing to a well-grounded apprehension about my health, I am unfortunately compelled to relinquish a lucrative and increasing medical practice, and to leave my native land for a more southern climate.

Feeling naturally and deeply concerned in the welfare of my patients, I am happy to say that I leave in my place a gentleman in whose professional attainments and skill I have unbounded confidence, and whose judgment, clear-headedness, and practical experience in matters of professional detail, I have seen more than once exhibited with effect. The gentleman I allude to is Doctor ———, who now occupies my late residence.

As I would entrust to Dr. ———'s care the life of any member of my family, so I can, with equal confidence, recommend him to you as your medical adviser.

While with many deep regrets, and a keen sense of sorrow, I thus sever my connection with my patients and friends, it is to me at least a satisfaction to feel that I am leaving to fill my place a more than worthy representative.

Wishing you every happiness,

I remain,

Ever sincerely yours, . . .

As we have already said, we regard this sort of thing as altogether inadmissible. A departing practitioner may, without impropriety, intimate to his patients and no one else the fact that he is about to leave and has transferred his practice to another, but, beyond this, any advertising circular, especially if addressed to other practitioners' patients, is totally inconsistent with professional decency, and reflects as much on the recipient of the laudation as on the author of it.—ED.

WESTON'S WALK.

WE are asked to mention that a special meeting of the British Medical Temperance Association will be held, in the rooms of the Medical Society of London, on Wednesday next, at 4 p.m., for the purpose of receiving the report of the committee appointed to make observations on Mr. Weston during the last week of his walk of 5,000 miles. All members of the profession are invited, whether members of the Association or not.

DR. BOWE.—No case should be given up as incurable in which only single remedies have been employed. It often happens that syphilitic patients who exhibit no kind of improvement under iodide of potassium will get rapidly well if submitted to the influence of mercury; and many other instances might be cited. You should pursue a plan on this principle in your case.

DR. FARMER.—There were twenty-two persons present, but none of them had ever been previously made acquainted with the nature of the resolution to be proposed. Under the circumstances, therefore, it does not seem to be just to the general body of members to publish the decision arrived at as being concurred in by the whole association. The majority was the narrowest possible.

F. W. B.—He only expressed an individual opinion, and it acquires all its importance from the subsequent discussion to which it gave rise.

MR. NEWMAN.—Nothing would be gained by publishing the facts. They are discreditable to all concerned.

DR. BRADY.—On application to the Registrar a circular containing all the particulars will be forwarded to you. We are unable to say in what particular way the exception was made.

Meetings of the Societies.

WEDNESDAY, MARCH 26TH.

ROYAL COLLEGE OF PHYSICIANS OF LONDON.—At 5 p.m., Croonian Lecture: Dr. Hughlings Jackson, Evolution and Dissolution of the Nervous System.

HUNTERIAN SOCIETY.—At 8 p.m., Mr. Hutchinson, Some Notes on Arsenic.—Mr. McCarthy will show some Osteotomies.—Dr. Stowers

will relate the Sequel of a Case of Paget's Disease of the Nipple.—Mr. Charters J. Symonds will show a Case of Scleroderma, with Gangrene of Fingers.

HOSPITALS ASSOCIATION.—At 8 p.m. (in the rooms of the Medical Society of London), Mr. W. J. Nixon (London Hospital), On the Difficulties associated with the Administration of the Out-patient Department, and how best to deal with them.

THURSDAY, MARCH 27TH.

ROYAL INSTITUTION.—At 8 p.m., Professor Tyndall, On the Older Electricity.

FRIDAY, MARCH 28TH.

ROYAL COLLEGE OF PHYSICIANS OF LONDON.—At 5 p.m., Lumleian Lecture: Dr. James Andrew, Etiology of Phthisis.

ROYAL INSTITUTION.—At 8 p.m., Professor Osborne Reynolds, Motion of Water.

CLINICAL SOCIETY OF LONDON.—At 8.30 p.m., Dr. Finlay, On Cases of Enteric Fever associated with Rheumatism.—Mr. Davies-Colley, On a Case of Dislocation of the Spine.—Mr. Durham, On a Case of Neuralgia successfully treated by Trephining.—Dr. de Havilland Hall, Sequel to a Case of Perichondritis of the Larynx.

Vacancies.

Birmingham Children's Hospital.—Dispenser. Salary, £80. Applications to the Secretary by April 1.

Brighton Lying-in Institution.—House Surgeon. Salary, £120, with furnished apartments, &c. Applications to the Secretary before April 4.

Chatham, St. Bartholomew's Hospital.—Assistant House Surgeon. Salary, £100, with board, &c. Endorsed applications to be sent in by May 1.

Flintshire Dispensary.—House Surgeon. Salary, £100, with furnished house, &c. Applications to the Secretary by April 15.

Northend and Tynedale Mining Company.—Salary, £100, with house, and liberty for private practice. Applications by March 29, to Mr. Hy. Hall, West Northend, Cumberland.

Appointments.

COXWELL, C. F., M.R.C.P. Lond., Assistant Physician to the Royal Hospital for Diseases of the Chest, City Road.

DAVIDSON, P., M.A., M.B. Edin., Assistant Medical Officer to the Infirmary for Children, Liverpool.

DAY, J. B., M.R.C.S., L.R.C.P. Lond., Clinical Assistant to the Brompton Hospital for Consumption.

ELLIS, R., F.R.C.S. Ed., Honorary Consulting Surgeon to the Sheffield and South Yorkshire Ear and Throat Hospital.

ERSKINE, J., M.A., M.B., C.M., Assistant Surgeon to the Glasgow Hospital and Dispensary for the Diseases of the Ear.

GARMAN, W., M.B., C.M. Edin., Resident Physician to the Queen's Hospital, Birmingham.

GOULD, A. P., F.R.C.S., B.Sc. Lond., Surgeon to the Royal Hospital for Diseases of the Chest, City Road.

MACPHERSON, R., M.B., C.M., Physician on the Staff of Anderson's College Dispensary, Glasgow.

REDMOND, J., L.K.Q.C.P.I., L.R.C.S.I., Pathologist to the Coombe Hospital.

SCOTT, J. W., late Surgeon R.N., Junior Assistant Medical Officer to the Hants County Asylum, Knowle, Fareham.

SMITH, W. B., F.R.C.S. Ed., L.R.C.P. Ed., Acting Medical Superintendent to the Sunbury Lunatic Asylum, Victoria.

SUNDERLAND, S., M.D. L.R.C.P., M.R.C.S., Resident Medical Officer to the Royal Hospital for Children and Women, Waterloo Bridge Road, S.K.

Marriages.

ATKINSON—CLARK.—March 20, at the parish church of Fangfosa, George Fernley Atkinson, L.R.C.P., of Snaith, to Mary Sophia, eldest daughter of Edward E. Clark, Esq., of Cowick, Selby.

BRADFORD—WELBY.—March 19, at the Cathedral, St. Helena, Surgeon-Major Robert Mark Bradford, to Edith Frances Welby, youngest daughter of the Lord Bishop of St. Helena.

Deaths.

ARCHER.—March 17, Surgeon-General Charles Archer, M.D., Deputy Inspector-General of Hospitals, aged 66.

AYERST.—March 15, at Stanbury, Torquay, James Smith Ayerst, M.D., aged 59.

DAVIS.—March 19, at 41 Boundary Road, St. John's Wood, John Hall Davis, M.D. Lond., F.R.C.P.

FOX.—March 17, at Rome, Edith, fifth daughter of the late Charles J. Fox, M.D., of Brington, Somerset.

FURLONG.—March 16, at Dolbadd, Carmarthenshire, after a short illness, Surgeon-General Furlong, Retired Half Pay, aged 61.

LEREW.—March 16, at Clifton Terrace, Malda Vale, W., William Kirby Lerew, M.R.C.S., L.S.A. Lond., aged 69.

REYNOLDS.—March 18, at Beckenham, suddenly, Samuel Reynolds, F.R.C.S., aged 87.

ROBINSON.—March 16, at Devonshire Street, Portland Place, W., John Robinson, M.R.C.S., aged 72.

TEEVAN.—March 22, at North End House, Croydon, John Teevan, M.R.C.S., aged 82.

THOMSON.—March 23, at his residence, Kensington, Allen Thomson, M.D. Ed., D.C.L. Oxon., F.R.S.

TOULMIN.—March 18, at his residence, Upper Clapton, Francis Toulmin, F.R.C.S., aged 81.

A CASE OF RUPTURED BLADDER AND FRACTURED PELVIS, WHERE MEDIAN CYSTOTOMY WAS PERFORMED. (a)

By REGINALD HARRISON, F.R.C.S.,
Surgeon to the Liverpool Royal Infirmary.

RUPTURE of the bladder is an injury of so fatal a character that it is desirable to record all instances where attempts have been made to deal with the lesion other than by that means which has hitherto proved of little avail, the introduction and retention of a catheter.

With the same desire as prompted Dr. Alexander (b) to bring before this Society a case of a somewhat similar nature, where he had opened the abdominal wall down to the peritoneum, I submit for your consideration and criticism the following particulars. It is seldom that an operative measure in surgery is perfected at once or by one man. We have but few illustrations of this; on the contrary, it is by the experience of many that precision eventually has been arrived at. Hence there is no case which has not its bearings upon the issue before us:—

On January 12th, 1884, G. H., æt. 29, was admitted into the Royal Infirmary, having tumbled from a railway waggon, a distance of about six feet, with a heavy "set," or stone on top of his pelvis. He was rendered unconscious for about five minutes.

On admission, some blood was found on the front of his shirt, and pelvic crepitus was detected. He was unable to pass water, and had not done so for three hours previously. A catheter was at once introduced,

and about eight ounces of urine, mixed with bright red blood, drawn off. I saw him six hours after this (11 p.m.) and removed with the catheter about five ounces more urine of a similar nature. The catheter passed easily, was not locked in the bladder, and the urine passed off in a steady stream. I also localised a fracture of the right pubic bone. The conclusion arrived at was that the bladder was ruptured, but there was some doubt as to the precise position of the rupture relatively to the peritoneum. I therefore determined to explore the bladder with my finger by a median opening from the perineum, and to shape any subsequent proceeding in accordance with what was found. This I accordingly did, and discovered that the rupture was extra-peritoneal and situated on the anterior wall a little behind the prostate. The opening admitted the index finger by which a fracture of the pubic arch could be felt. The position of the rupture decided what should be done—a large lithotomy tube was passed into the bladder from the perineum through which drainage could be carried on.

Jan. 13th, 10 a.m.—The patient had passed a restless night, but was not in pain; the urine came away freely slightly tinged with blood. 5 p.m.—Much pain complained of in lower part of abdomen. Pulse, 95; temperature, 99 deg. He vomited everything, and complained intensely of thirst. 8 p.m.—As the pain and vomiting continued nothing was given but ice and small doses of opium.

Jan. 14th, 2 a.m.—Complains of much pain over lower part of abdomen; fomentations applied; pulse increasing in frequency; temperature, 101 deg.; urine drawing away freely, and natural in appearance. At 2.30 a.m., the excretion of urine suddenly ceased. It was thought that the tube might be blocked up, but this was not the case. At 8.30 a.m. the patient collapsed suddenly, the abdomen remaining soft and compressible to the last. It was subsequently found out that the patient had only left his bed a fortnight previously, after an attack of scarlet fever.

(a) Read before the Medical Institution, Liverpool, March 13th, 1884.
(b) Liverpool Medico-Chirurgical Journal, January, 1884.

The patient lived thirty-two hours after the cystotomy, during twenty-seven hours of which urine was freely passed through the tube. No urine seemed to have been excreted during the last five hours of his life. The operation of opening the bladder was done on a staff, it only occupied a few seconds, and may be said to have been bloodless.

Post-mortem Examination.—On opening the abdomen there were found signs of commencing peritonitis; there was some serous fluid in the pelvis, but no blood. The visceral peritoneum, covering some coils of small intestine in the pelvis, had lost its gloss, and the whole of the pelvic peritoneum was rough and injected. The space in the lower part of the anterior abdominal wall between the two layers of the transversalis fascia leading down to the bladder (porta vesicae of Retzius), contained some bloody urine. This space was found, on passing a finger into the bladder through the perineal wound, to be in communication with a laceration in that viscus, situated on its anterior aspect a little behind the prostate. There was no laceration of the peritoneum; the bladder was empty. The pelvis and contents were then removed, and are now submitted for examination. They include the following injuries: A lacerated wound of the bladder, in the situation before mentioned, about three-quarters of an inch long, and a similar one in the base of the trigone; a laceration of the perineal tissues below the level of the urethra, but communicating with the operation incision; a fracture of the right side of the pubic arch could be detected by the finger both from this and from the vesical wound; much effusion of blood beneath the pubic fascia in the neighbourhood of the right sacro iliac synchondrosis, and a similar but rather smaller collection of blood in the sub-peritoneal tissues on the left side around the upper part of the obturator foramen with complete division of the obturator artery and vein. There were in all six lines of fracture of the pelvic bones. The transverse and descending rami of both pubic bones were broken through about the point of their junction with the ilium and ischium. The left descending pubic ramus was also broken across near its junction with the body of the bone, and on the right side there was a complete vertical fracture of the sacrum running through the anterior vesical foramina.

In this case the rupture of the bladder was undoubtedly caused by a penetration of the fractured pelvis. Where rupture of the bladder is complicated with fracture of the adjoining pelvic bones the opening into the viscus is usually extra-peritoneal; where the rupture is not thus complicated it is intra-peritoneal, and is generally found in the base or posterior wall.

In investigating injuries involving the parts constituting the neck of the bladder, in which I include the membranous urethra, I have experienced difficulty in satisfactorily explaining how it was that the membranous urethra was sometimes ruptured without fracture of the pelvis co-existing, whilst there was no evidence that the perinæum had ever been struck.

In treating of rupture of the urethra, Bryant refers to this point in the following words: (a) "In not a few instances the injury (ruptured urethra) has been produced by the passage of a cart-wheel across the pelvis. It is somewhat difficult to understand how such a result can be produced by such a cause, unless some fracture of the pelvis co-exists; but explain it how we may, in practice we meet with cases of ruptured urethra following upon the passage of a wheel across the pelvis, and unconnected with any other symptom of its fracture."

In some instances of ruptured urethra I have seen in young subjects, where the force has been applied to the sides of the pelvis, as in crushes and squeezes, and not to the perinæum, as is more commonly the case, I feel convinced that the tearing of the urethra more or less across is occasioned by the bowing or bending forwards of the circle of the pelvis at the symphysis pubis under

pressure applied to the sides. In this way, by the sudden elongation of the antero-posterior diameter of the pelvis, the urethra is put on the stretch and gives way at, or immediately behind, the point where it passes through and is fixed to the deep triangular ligament.

In the case I have narrated the very extensive injuries to the pelvic bone, and possibly the condition of the kidneys consequent on the attack of scarlet fever, placed the patient in the most unfavourable position for any hope of recovery. I believe he died from shock more than anything else. As a rule, however, cases of ruptured bladder owe their almost unexceptional fatality to the rapid development of acute peritonitis provoked by the retention of blood and urine. Here this symptom, though possibly sufficient time had not elapsed for the full development, seemed to be in check. It is, however, to the management of the urine in this class of cases I wish more especially to direct attention. I do not think the transition-contact of healthy urine with any tissue of the body, such, for instance, as the peritoneum, is necessarily provocative of inflammation. Meizel's experiments, as well as clinical observations where recovery took place, though there can be no doubt that urine actually passed into the peritoneal cavity, from whence it was removed, warrant such a statement.

A bruised tissue, or urine rendered morbid either by decomposition or admixture, represent very opposite conditions, or those where inflammation of the most acute and destructive form is sure to be provoked by contact of this kind. In some cases I have seen where the bladder has been burst like a paper bag suddenly compressed, pent up urine which has been left to decompose in the peritoneal cavity has practically been the cause of death. From a careful consideration of these accidents, and some records relating to their treatment, together with an experience of my own, I have resolved for the future to adopt in principle the following procedures, subject to such modifications as may, from time to time, be required:—

1. To open the bladder from the perinæum and to carefully explore with the finger. I should prefer this as a preliminary to opening the abdomen, as the latter might prove to be unnecessary by reason of the rupture being extra-peritoneal. If exploration determines the necessity for such a complete examination of the fundus of the bladder as can only be afforded by laparotomy the perineal opening will still be desirable for the most effectual form of bladder drainage.

2. If the rupture prove by perineal exploration to be extra-peritoneal, the insertion of a bladder tube for drainage similar to what is adopted after lithotomy. In the case I have recorded the urine escaped readily so long as the kidneys excreted it; the post-mortem examination showed no indication either of lodgment of urine, or urinary extravasation.

3. If the rupture on exploration proves to be intra-peritoneal, and there is consequently a probability that urine has passed into the peritoneal cavity, the further proceeding of opening the abdomen with the view of clearing out the peritoneal cavity will be determined by two considerations, (1st) relating to hæmorrhage, and (2nd) to the question of urine drainage. If the urine is deeply tinged with blood, and clots escape from the bladder through the exploratory wound, then I think that laparotomy should be proceeded with, as it is extremely likely, especially if there has been much delay, that clots will be found in the abdominal cavity, these, with a small admixture of urine, will most surely occasion acute peritonitis.

Rivington (a) observes: "A considerable amount of blood has been found in a few cases in the abdominal cavity. When Mr. Heath operated he was surprised at the amount of clots which had to be taken out of the peritoneal cavity; and at the post-mortem in Dr. Dewar's case three pounds of clotted blood were removed.

(a) "The Practice of Surgery."

(a) "Rupture of the Urinary Bladder," 1884.

In one of the cases reported by Mr. B. Cooper, three or four pints of nearly pure, uncoagulated blood were found effused into the cavity of the peritoneum."—P. 25.

If, however, on exploration the urine escapes with only a slight admixture of blood, as frequently has been the case in recorded instances where the catheter has only been used, and which has been verified by post-mortem examination—then the question arises, Will a perineal incision and a drainage-tube be sufficient to prevent urine finding its way into and lodging in the peritoneal cavity?

Assuming that we are dealing with a case of intra-peritoneal rupture of the bladder, where the laceration is necessarily above a horizontal line drawn between the openings of the two ureters, and that we have a normal bladder and prostate, I undertake to say that, if an incision is made from the perineum through the neck of the bladder, such as we employ in the operation of lateral lithotomy, and we then put in a tube, as after the latter operation, not one drop of urine will find its way into the peritoneal cavity.

Apart from conclusions drawn from my own observation of wounds made into the bladder for a variety of operative purposes, I would seek to substantiate the assertion I have just made by the post-mortem records of ruptured bladder and the structural arrangement of the normal bladder.

As Mr. Rivington (a) observes, "the records of post-mortems on the intra-peritoneal cases prove the frequency with which the bladder is found contracted. In 27 out of 34 the bladder is described as contracted, in two as empty, in one as collapsed, in one as not fully contracted, in one as contracted to one-third its natural size, in one as not much contracted, and in one as much enlarged. In some the contraction was very considerable, being described as 'very much contracted and entirely empty' (Cusack), 'firmly contracted,' 'completely shrivelled up around the entrance of the urethra,' &c."

Furthermore, the connections and muscular construction of the bladder are such as to favour the escape of urine through its neck, provided adequate means are adopted for entirely suspending the sphincter action which controls micturition. The trigone, which we all know is immediately below the orifices of the ureters, is exceedingly smooth, and by reason of its connections and construction is incapable of contraction. In making the assertion that, if in a case of ruptured bladder an incision be made into the neck urine will not find its way into the peritoneal cavity, I limit the kind of incision to that which is usually employed in lateral lithotomy, for reasons that must be well known to every practical lithotomist. In the selection of this procedure I have the support of Rivington (b) who observes: "in lateral cystotomy the knife would be able to cut freely into the prostate, and reach the neck of the bladder, which would be slow to regain its retentive power. This constitutes the great recommendation of the lateral operation, and no other measure appears to me to equal it for efficiency in this important direction."

Six cases, with three recoveries, are briefly referred to by Stein (c) as illustrating the employment of lateral cystotomy for rupture of the bladder. The greater number of these can hardly be regarded as testing the value of this procedure under these circumstances, as the operation does not appear to have been performed for considerable periods of time after the injury, and on the development of signs of peritonitis.

In conclusion, in a case of ruptured bladder, I would say do not trust to the catheter, except as an aid to diagnosis—perform without delay this lateral operation as for lithotomy—explore carefully with the finger; if the rupture prove to communicate with the cavity of the peritoneum, and there are reasons for believing

that hæmorrhage either has been or is going on, or the bladder is not contracted sufficiently to prevent urine from passing into the cavity of the peritoneum, open the abdomen with the view of removing clots and urine from its cavity, and closing with sutures (as Willele (a) and Heath (b) have done) rupture in the bladder.

If the laceration prove to be extra-peritoneal, be content with the introduction of a tube from the perineum to permit of continuous drainage being carried on.

The Gulstonian Lectures

ON

NEUROSES OF THE VISCERA.

Delivered at the Royal College of Physicians, London.

By T. CLIFFORD ALLBUTT, M.A., M.D. Cantab., F.R.S.,
F.R.C.P. Lond.,

Senior Physician to the Leeds General Infirmary; Consulting Physician to the Leeds Hospital for Women and to the Fever Hospital.

LECTURE II.

WE are thus led to the cases which stimulate gastric ulcer; and in which, as I have said, diagnosis, often difficult, is sometimes impossible. No doubt, I have at times mistaken a case of ulcer for gastralgia, and at other times have assumed the existence of ulcer when gastralgia and gastralgic vomiting alone were present.

Such cases, if not familiarly known to the profession, are, at any rate, so far known to the closer observers as to make it unnecessary for me to give the long case-histories which such patients afford. Taken shortly, we find this form of gastralgia most frequently in young women; and it is marked by the sequence of ingestion of food, severe pain in the stomach, vomiting, and relief. The pain may occur only on taking food, and vomiting may give speedy relief. It is not an uncommon thing, we know, for young women to produce blood in irregular ways by the mouth, sometimes repeatedly or in quantity, even when all parts are free from disease. If such an appearance should be found, the diagnosis of ulcer becomes almost inevitable. Indeed, blood or no blood, it is often hard to come to an opinion which shall be confident enough to justify us in withholding foods on the one hand, or, on the other hand, in pressing stomach-nutrition gently but firmly forward. But according to the correctness of our judgment must our treatment be helpful or positively mischievous. Probabilities do not aid us much, for I think the ulcerous and the pseudo-ulcerous cases are about equally common. The catamenia may be absent or present in either case, nor do I agree with a writer in "Quain's Dictionary" that gastric neuroses in women especially frequent the catamenial periods. In so far as these act as general depressants of vitality, they may open the way to an attack, as may any other exhaustion; but I do not find among the genuine gastralgias a consensus of cases showing any more direct or any very frequent association of the kind. Emaciation is, perhaps, rather more usual in the neurotic than in the ulcerous disease, but this cannot go for much, nor can chlorotic anæmia, which may be seen in either form. Pain in the back is as common in gastralgia as in ulcer. In these doubtful cases we must try to reach safe ground by a careful review of the patient's life-history, diathesis, and associated symptoms; and we can often attain this position by the discovery of neurotic antecedents, and of some previous irregularities in the now associated symptoms. We shall find, perhaps, that vomiting and pain have been dissociated in the past; that the pain has been noc-

turnal, or otherwise periodic; that there have been voluminous flatulence, cravings, sinkings, and so forth. With such commemorative symptoms, both as regards stomach and other parts, we may sometimes recognise gastralgia clearly enough, even in spite of the occasional appearance of some ejected blood. Hyperæsthesia of the stomach is not of course always, nor even generally, associated with vomiting. Many persons have alighter degrees of such hyperæsthesia, and suffer some discomfort during digestion, either because digestion is slow and defective, or because the stomach resents even a normal digestive process. When such discomfort becomes an ache, the patient calls himself a dyspeptic; when the ache rises into an agony, we have a very grave malady to deal with, even if there be no vomiting nor tendency to vomit. This state of stomach much resembles that of the uterus in the irritable uterus of Gooch, and of the spine in the irritable spine of Teale and Griffins. It cannot be doubted, I think, that these three maladies, coincident as they often may be with hysteria, are nevertheless essentially independent of it. Irritable spine is found frequently, no doubt, in the plump, listless, and egoistical victim of hysteria; but it occurs likewise in the higher class of neurotics. I am attending such a case of spinal irritation at present, with Mr. Richardson, in Leeds. The young lady is not only cheerful, alert, unselfish, and worn in flesh, but she is full of will and energy in her efforts to carry out any troublesome plan of treatment we may suggest. I take her complaints as literally as I do the complaint of any other sensible and temperate person who says that he is suffering from some unseen distresa. (a)

Irritable uterus, again, in spite of the mechanical school, is a genuine neuralgia in many persons, as it may be an affected malady in others. Irritable stomach is a grim reality in no less a number, though hyperæsthesias and anæsthesias, as functional disorders, do, no doubt, belong, also, to the hysterical; and it may, indeed, be hard to say, in a given case, where active neurosis ends, and where a brooding persuasion of pain begins. We have types intermediate between the sleek religious woman, who knits antimacassars, and lives upon her friends; and the hollow eyed, fiercely active, wan woman, who, labouring ever for others, tries to hide the wolf within her, even from herself. Before Lasague and Sir William Gull published their cases of anorexia nervosa, I had myself collected six cases, with a view to a publication, which thereon became unnecessary. For these cases, I would deprecate the stereotyped use of the name anorexia hysterica. In some of these cases there is (4) great pain on the ingestion of food; in others there is no pain, but simply a distaste for food. This distaste has arisen in most of them, however, from some discomfort, which at one time accompanied digestion, a discomfort which may have taken its rise either in dyspeptic or neurotic causes. Sometimes, the distaste has taken its origin in a mere shirking of food—in fear of growing stout, or in a nobler avoidance of self-indulgence. However established, the distaste, as we know, often becomes invincible, even when eating is unattended with gastric hyperæsthesia. If I were to judge by my own original cases, I should fail to see how the word hysterical could usefully be applied to any of them; in three of them, the word would be absurdly out of place unless we are to apply it to any nervous malady in any woman whatever. This anorexia nervosa is no whimsical malady, no inconsistent nor irregular indisposition, but is a definite complex, consisting, in part, of objective symptoms. With more constancy than is commonly found in disease, we find the malady as follows:—It occurs in young women, and nearly always in those who inherit a decided neurotic taint. Five objective

symptoms are always present, viz., amenorrhœa, constipation, subnormal temperature, slow pulse, and cold extremities. To these we may add a degree of emaciation proportionate to that of the malady, and a tendency to loss of hair from the scalp. The first five symptoms are observable long before they would appear as simple results of inanition. In some of these cases, as in Mr. Skey's, the pain which follows the use of food is agonising. I have a case in my mind of the last degree of severity, for her agony on the reception of a cup of lithed broth was extreme. I mean that she would shrink away unnoticed and uncomplaining into any remote corner, where she might moan to herself, unconscious of any observation. Now, to this lady, like all the sufferers of this class to which I have referred, the airs and humours of hysteria were wholly alien. Her daily life, even in the days of her weakness, was full of energy and of well directed good works. Her habits were punctual and methodical, and her affections stanch and wholesome (a). She never vomited her food, nor have I found vomiting in any cases of anorexia nervosa. The chief variation in the group of symptoms in these patients is in the presence or absence of pain. Pain, so acute in a few, is in most of them absent or insignificant. In the latter, exists simply an invincible distaste for food. To yield to such a distaste seems at first to many high-spirited girls rather, perhaps, a merit than otherwise—it seems but a distaste for indulgence, a denial of the animal propensities. Thus creeps on unknown or unconsidered an aversion from food, and indeed, an inability to take full meals, which seems, in some cases, almost unconquerable. If the fear of such a state becomes more prevalent among the public, it is probable that the known results of such mistaken self-denial will serve in future as a timely warning to prevent the full establishment of the distaste.

Hyperæsthesia of the stomach, then, may be found in anorexia nervosa, and to such cases is a grievous addition; in gastralgia of the periodic type, when it may concur with the attacks, or alternate with them, or, again, it may itself constitute a form of gastralgia, a form in which pain occurs only during digestion. These cases are constantly confounded with dyspepsia; but the term can only be applied to them etymologically. For instance, No. 356, 1878, is a solicitor, æt. 31. He called upon me to complain of "grievous indigestion of long standing." Soon after meals, pain would come on at the epigastrium, after a time generalising itself about the chest or waist. It would last from one to two hours, and it never occurred on an empty stomach, not even if the due hour of a meal were over passed. Now, this surely seemed due to some defect in the peptic process; and, if it were not, how were we to distinguish its cause? Well, his tongue was quite clean, his secretions normal, and he had no offensive flatulence. Nor, again, did he much care what he ate; all things gave him pain alike, except that one thing, beef, which especially tries the neuralgic stomach. But fatigue or annoyance increased his liability to the torment. Sometimes, the pain had given place to a pain in the head, or sometimes it had "pinned him through the body." A year before this stomach-disorder set in, he "was demented with neuralgia in the head," but had suffered thus but little since. Before that, again, he had had a well-marked but brief attack of melancholia; his brother had hay-fever badly, and the family-history is neurotic in other respects. Here the gastric pain then seemed to be of the hyperæsthetic form of gastralgia; nor was the diagnosis ultimately difficult unless we are urged to confound it with hysteria. No stomach-medicines could relieve such a patient, and this one was cured with Easton's syrup. In other cases, diagnosis might not be so easy as in his, and in some mixed cases it is very difficult to disentangle the pains which are caused by neurotic

(a) I cannot forbear to refer in this place to the admirable service Dr. Handfield Jones has done in warning us against the delusive phrase of "hysterical pain." Dr. Kent Spender offers the same testimony in his work on "The Relief of Pain," p. 65.

(a) Lasague notices the briskness and energy of these patients, and gives a very fanciful explanation of it.

hyperæsthesia from the pains which are caused by the presence of products of abnormal digestion. In Miss — (No. 311, 1879), pain during digestion occurred as in the last case, and there were present also the characteristic nocturnal seizures. Miss — (No. 31, 1880), suffered in like manner during digestion, but with great severity. It is strange to see that in her case the group of symptoms called anorexia nervosa never arose. She was pallid, emaciated, highly neurotic, and dreaded food. Still, her pulse was rather quick, as well as feeble; the catamenia were regular, though scanty and watery; constipation was not well-marked; and she manifested no loathing of food, but would gladly have eaten if she had dared. This lady had the abdominal aortic throb, and also, when the pain came on during digestion, her mouth would fill with clear water. It was a great pleasure to me to restore this valuable life to health and activity after a long illness. A combination of morphia with arsenic and quinine, administered with food, did best service.

In Miss — (No. 538, 1882), the pain only came on after distinctly improper food, such as tough beef, new bread, and pastry or cake. Here is a transition towards maldigestion. But the pain was so intense as to point rather to a neuralgia aroused by peripheral causes, and, moreover, pain was not unfrequently aroused by the same cause in the left orbit, or in the brachial plexus. The three pains might come separately, variously combined in pairs, or all together. This case reminds us of Watson's instance, in which a severe pain in the foot was brought on by eating an ice. I may indicate again the curious fact that such gastralgias may be associated with vomiting, or they may not be. In some cases, a tendency to reflex motor spasm is there, in others it is not there. The former cases simulate ulcer, the latter do not; for I presume that vomiting is aroused in all grave cases of ulcer.

Miss —, æt. 22 (No. 416, 1883), came under me for intense pain after food, with vomiting and consequent relief. She was sent to me as a case of *ulcus ventriculi*, and I could not promise her at first that it was not. But her family history was neuralgic, and she used to be a "martyr to tic." Now, "the food makes her so sore and hurts her so," but she is relieved by vomiting. Whether the point be fit for universal application or not, I cannot say; if it be, it is worthy of a pointed reference—namely, that I found warmth always gave relief in her case. I directed her to drink hot water with her dinner, and after a meal to lie down under a rug with a hot bottle to the epigastrium. This gave her much comfort but it probably would not have relieved the pain of ulcer. On the other hand, in her, as in many like her, cold feet would precipitate an attack. This lady was quickly and completely cured by anti-neuralgic remedies.

Finally, we must remember, nevertheless, that, in organic disease of the stomach, the pain may be independent of food. Mrs. —, æt. 52 (No. 240, 1882), consulted me for pain, which was independent of food, and thus closely simulated simple gastralgia. There was no neurotic history, nor was the pain periodic. She vomited catarrhal matters; but some gastralgics vomit gummy phlegm with their attacks. The diagnosis was very difficult, until progressive emaciation and loss of complexion compelled us to infer the presence of carcinoma, an inference which was but too surely justified by the result.

One symptom very characteristic of gastralgia next demands our attention, and that is flatulence. The flatulence of a typical gastralgia is a portentous thing. Like vomiting, like hyperæsthesia, it may concur with the pain, or come independently of it. It returns often in attacks as the pain does, striving vehemently, so that the occurrence of this wind and gastralgia make up the malady known as "the spasms." That such distensions and belchings as these are of other origin than the maldigestion of food is, I think, very imperfectly realised by

the profession at large. But in its more striking forms its independence of such causes is obvious. It recurs often with the same periodicity as gastralgia itself, and, like it, has a fondness for the small hours of the afternoon or of the early morning, especially of the latter. The patient awakes, let us say, at 2 or 3 a.m., with a sense of distension which he knows but too well. His body is sometimes flat, but more often has swelled about the epigastric region, and becomes tight and hard. For a while, restless and distressful, he rolls upon his face, and rubs his belly until "the wind begins to move." This, as it does so, rumbles upwards rather than downwards, and delivers itself by no common eructation, but the working load rises in a series of eruptions, which roll from the throat in successive waves of flatuosity. It is a prolonged storm rather than an explosion, and its tumult will keep the patient raised in bed, heaving in strife with it for an hour or two before he finds ease.

Miss —, æt. 23 (No. 233, 1883), *migraineuse*, is liable to violent attacks of flatulency. It awakes her in the night. She has no pain but great distress; wind works upwards in enormous volumes. Her tongue is clean and tremulous, and secretions normal. The gases ejected are innocent of all odour. The uterine functions are normal. It is not stated that this lady ever had gastralgia at all; certainly she had not at the time of my notes. A like state of things existed in a friend of my own, whose mental and bodily activities are incessant, and who has suffered greatly from gastralgia. He had consulted physicians high and low, home and foreign, and his flatulence had invariably been put down to "indigestion," and he was consequently dieted into still farther emaciation, and still profounder gastric distress.

Miss —, æt. 29 (No. 374, 1881), has gastralgia well marked, but complains as bitterly of flatulence. This always comes on upon an empty stomach, and is sure to be generated on the delay of any meal. It "rifts up voluminously."

Mr. H. (No. 629, 1880), has had psoriasis for years. He is subject to attacks of "sinking in the stomach and bowels, as if actually dying." He never had pain, but he has "rounds of intense and tremendous flatulence . . . always on the empty stomach."

Again, Mr. —, æt. 47 (No. 72, 1879), always "delicate," has gastralgia, at present daily. It recurs exactly at 4 p.m., and he hastens to relieve it by food. It is thus postponed till 7 p.m., when it is again put off by dinner. He is thus at rest till 4 a.m., when he is always awakened by "loud, noisy, and continuous belching . . . with great rollings of wind and most painful distension." He presents no signs of disease anywhere, nor of disordered secretion. He never vomits; he has no discomfort from careful meals, but the reverse. He has had a continuous loss of blood from piles for a long time, and he looks anæmic. This fact he omitted to state until directly questioned, for he believed "that relief to be good for the system," and calculated to clear his "torpid liver." All these people are profoundly convinced that the main enemy is a vicious liver.

I will give but one case more: A solicitor, æt. 30 (No. 73, 1878), had been very hard worked. First came dull heavy pain in the left side. Then he became subject to "painful distensions of the body, not by food," and extreme flatulence; with this comes on great dyspnoea, like spasmodic asthma, or again dizziness so severe that he fears he may fall. He passes profuse and pale urine at such times, and if a woman he would have been written down a hysteric; whereas he is a man of intellect and good sense, and holds successfully a high professional position. The only difficulty in his case was to secure for him a sufficient rest. It is to be noted that in all these cases the wind is quite inoffensive. Whether it be carbonic acid, common air, hydrogen, or what else, I am unable to say, as I have never tested it. By its mode of occurrence, the suddenness and volume of its generation, as well as in its innocence of taste or odour, it is clearly marked off from the foul wind generated by the fermenta-

tions of food. It is certainly produced in some way by the agency of the nervous system. Such are the painful symptoms which may be observed and discussed under the head of gastralgia; but a few yet remain.

There is a distension of the body, real or false, which sadly distresses some patients. Women having this distension must, perhaps, go upstairs to remove the corset to obtain ease. The swelling is, for the most part, real and measurable; but I am not prepared to say what is the cause or mode of it. That it is a mere accumulation of wind, I hesitate to suppose. It is often unassociated with any consciousness of the presence of flatulence; and, moreover, it is not confined to the region of the stomach. I am assured by many patients, and their observing friends, that it may extend all over the breast, and even to the neck. It may be vascular, but there is no blush with it.

To the horrible, death-like sinkings that belong to gastralgia, though not always actually coincident with the pain, I have already referred incidentally. No. 80, 1874, a male, æt. 28, after a few months' worry, began to have neuralgic pain in the left arm and up the neck. After this, he became subject to nocturnal attacks of "want"—not a craving, nor exactly a faintness, but "an awful emptiness, with a dread at the heart." He was substantially quite healthy, and was soon cured on restorative and tonic treatment. I am now seeing a similar case in Leeds, with Mr. Robson, in a neurotic subject. Vertigo is sometimes associated with this symptom. Slighter degrees of this distress often accompany gastralgia or enteralgia, or, with an unaccountable languor, precede them. These subjective sensations are, of course, to be distinguished from the collapse, sometimes alarming in its degree, which is consequent upon the intenser attacks of abdominal neuralgia. The intensity, indeed, of most severe cases of gastro-enteralgia may be seen in the ashen cold face and blue nails. Finally, most gastralgics are subject, not when actually suffering only, but also at all times, to borborygmi. Few people are ignorant of this phenomenon; but it is in neurotics especially that it reaches its most lively and garrulous form. An old and valued domestic, who has recently retired after twenty-five years of household service, and who presented all the phenomena of gastralgia in an active form, was so embarrassed by these audible internal questionings that she almost withdrew herself from waiting at table. In some persons, borborygmi are rhythmical, and coincide with the inspiration. The noise is then rather of a churning character, and, I believe, is made in the stomach only. On examination, it will be found that, in these persons, the breathing, when full, is wholly abdominal. Even in women the thorax may be motionless. In addition to tonic measures, gentle dumbbell exercises are most potent to remove this disorder.

And now, gentlemen, have I succeeded in enforcing that which you already know—namely, that all the symptoms I have discussed to-day form, not only a consistent, but a very uniform series? Few maladies present a more definite series, or one more capable of rational explanation. Is it not one of the last maladies to be classed with those of irregular, capricious, and fanciful evolution? Shall we then say, as the authors of our text-books do to this moment, that gastralgia is, for the most part, a malady of hysterical women? If we still say so, then it is indeed time for the lion to paint the man.

THE annually recurring questions relative to the Contagious Diseases Acts have commenced in the House of Commons, and, in answer to Mr. Cavendish Bentinck, Mr. S. Smith, and Lord E. Cecil, Sir William Harcourt replied that the statement made by Mr. Blackwood, "that the administration of these Acts demoralised the police, and that women had been sent to prison without trial," was utterly devoid of foundation.

TORTURE: AN INCIDENT IN INDIAN MEDICAL LIFE.

By JOHN ROCHE, M.D.,

Retired List, Bombay Medical Service; formerly Civil Surgeon, Kotree, and Civil Surgeon, Hyderabad, Scinde, India.

IN the year 1869, a retired sepoy cut the throat of his paramour at night time in a village of the Shikarpoor Collectorate, Upper Scinde, India, and was soon placed under arrest. He had raised a noise and pretended that the murderers, after entering the house where he lived and after committing the crime, had escaped. Mr. de R., the son of a Dublin gentleman, was deputy collector and magistrate of the Talooka in which the deed was done; he investigated the case, and forthwith returned the individual charged to be tried by the district judge for wilful murder. The evidence was most conclusive. However, in about a fortnight the features of the affair were suddenly changed by the prisoner's brother appearing one morning at Shikarpoor before Col. D—, and stating that his brother had been tortured in jail into forced confession by having a galvanic battery applied to his private parts, and by having his feet burned, and that the authors of this diabolical conduct included the magistrate, Mr. de R., and the Civil Surgeon, Sheikh Sooltan, M.B., of the Bombay University. Forthwith, Col. D— despatched Mr. F— to investigate the case which, from *prima facie* evidence, was pronounced to be complete as to the torture. Mr. de R. hastened to Shikarpoor to remonstrate with his chief because he was suspended in his district *ultra vires* and hurriedly, and prejudicially condemned. Col. D. would not receive him nor hear him, for having left his district without leave. Mr. de R. proceeded to Kurrahee and sought an audience from Sir W. Merewether, where he was again rejected, on account of being absent from his station without permission. Mr. de R. further left for Bombay to see the governor and lay his case before him, but he did not fare better, an interview was denied as it was telegraphed from Scinde that he had not permission from his superior. When passing through Scinde Mr. de R. called me, who was Civil Surgeon at Kotree, to see him one night, when I had only a very short conversation with him, which convinced me that he was a gentleman of quick intellect, of much wealth of language, and apparently a *gentleman* in acts and superlatively so in manners. At the time his name was universally calumniated by the official community in Scinde; so it behoved one to be very circumspect and guarded in language which would insinuate anything to throw doubts on the charge that was circulated against him. Sheikh Sooltan, the Civil Surgeon of Mr. de R.'s Station reported himself sick and departed down the Indus. It was mooted that he had left his post without leave, and being implicated with Mr. de R., should be treated in like manner. I had a communication from my chief, Deputy Inspector-General Mahaffy, C.B., that Sheikh Sooltan, M.B., was on his way to Kotree, reported to be not sick, but that as he had been reporting himself suffering from fever and ague for some months, I should be very guarded and examine him most carefully, and, if I found him ill to treat him, and if shamming to deal with him accordingly. On his arrival at Kotree I perceived he was intensely malarious, and had an attack of fever every day, which I reported to my chief. In conversation over the torture episode, I ascertained that the sepoy in question was a paramour of the murdered woman, was living with her the night of the crime, had been in the service for 12 years, during which time he served as hospital orderly at Kurrahee, where a galvanic battery was used. Dr. Sheikh Sooltan had a galvanic battery which he used in his practice, and which circumstance was known to the accused murderer. I also heard Dr. Sooltan describe the extent of the burn, its nature and character, and was satisfied that, being on the sole and side of the foot, and healing after a few days' treatment, it was more likely to be produced by a burning rag or wisp of hemp than by heated wood or iron as imputed. Now, as a general rule, if torture be applied to extort confession of guilt, it will be applied

in some part sensitive and not easily exhibited, such as the genitals or anus; whereas, if used for the purpose of imputing it to others, it will be applied to the parts which are constantly exposed and which will call forth pity, such as the face, hands and feet. If torture be used by an outside person it will be through an instrument easily regulated, and if by oneself it will be such as can be had to hand. The description of the wound accorded with what a burning rag or piece of tow would produce, not what a defined piece of wood or iron would cause, and as for the galvanic battery there is nothing would make such an impression in a native hospital orderly as the sight of it at first, and there was no talent required in describing the action of that which was different from everything else, and which was the lion as it were of the whole fold. I became convinced that the charge of torture against Dr. Sheik Sooltan and Mr. de R. was cruelly false. I stated so to a relative of the Governor of Bombay, who was staying with me at the time, and who asked me to place my argument in writing, which I willingly did. Mr. V. F. essayed to defend the charge against Mr. de R. on my lines before a large group of officials at a dinner conversation, and appealed to me, when, with much nervousness, I endeavoured to explain why it was not at all so certain that Mr. de R. and Dr. Sheik Sooltan were guilty of torture such as might be common in days of native rule. Suffice it, that I induced the governor's relative staying with me to place the facts per letter before his Excellency and to have the two sides heard in the case. An inquiry was granted, and after an interview with Mr. de R., the inquirers were perfectly convinced that the torture was a trumped up case. Mr. de R. was rehabilitated and took leave to Europe. I heard from a clergyman of the Indian Establishment whom I met the other day and was acquainted in India with the facts, at present Mr. de R. is governor of a colonial island. He has not the remotest conception of how he was saved from ruin.

Clinical Records.

ST. BARTHOLOMEW'S HOSPITAL.

Case of Right Hemiplegia, followed by Epileptic Attacks—Albuminuria.

Under the care of Dr. REGINALD SOUTHEY.

(For the report of this case we are indebted to Mr. ALBERT GRESSWELL, B.A. Oxon., M.R.C.S.)

WILLIAM F., *æt.* 53, a well-built, corpulent man, by occupation an engine-driver during the last twenty years, was admitted to Matthew Ward on July 19th, 1882, and died on July 23rd. He went to work apparently well on July 19, at 3 p.m., and was brought in about 11 p.m. the same day. When first seen in the surgery he was lying calmly on the stretcher; he spoke rationally, but with very indistinct articulation. He could move his left leg freely, but when asked to move his right one he said "I can't." When also asked to move both arms he moved them freely, and he could put out his tongue. About a quarter of an hour after being brought to the surgery he suddenly became quite unconscious. The left pupil dilated to its full extent, and became fixed. The right arm also became paralysed, the left side of the mouth was puffed out with each expiration, and his breathing became stertorous. Shortly before the fit he sat up, asked in an excited manner for a urinary vessel, and then immediately passed water. He then fell back and became quite unconscious, as mentioned above. His wife told us that he had been complaining for some weeks of great languor after his work, and of some loss of appetite, and that he went to work apparently pretty well this morning. She said he had been in the habit of drinking moderately, had been laid up seven months with rheumatic fever about two years ago, and that he had had a little cough for a long time, but never spat blood. His bowels were generally regular, and he had passed water frequently during the night for some years past. He had never complained of momentary loss of his senses, or of giddiness, and he had never had any fit before of any kind. He was a

largely-framed, fat man, of fair complexion, and his skin was moist and rough. When examined in the ward his left pupil was dilated and fixed, and the left side of his mouth retracted. His tongue was flabby and moist, and the cervical glands were enlarged. The lungs were normal. The impulse of the heart was forcible, the apex indefinable. The precordial dullness was slightly encroached upon by pulmonary resonance. The heart sounds were distant but clear. Pulse 120, arteries hard and tortuous, temperature 99°6'. There was a papular rash over the right hypochondrium. Right upper and lower extremities were paralysed. Both legs and feet pitted on pressure. Patellar reflex marked at each knee. No patellar or ankle clonus. Very slight reflex excitability of the right sole; marked reflex excitability at the left sole.

Ordered—D.L. Beef tea. Balneum vaporis.

Hms. c. m. s. 3ij. statim.

Hst. sennæ co. 3iss. statim.

July 20th, 1 a.m. —Has been quite unconscious, and very drowsy through the night. Breathing stertorous. Left side of face twitching violently every two or three minutes. Left angle of mouth still drawn up. Constant movement of the left arm and fumbling about with the bedclothes. Temperature of right side 100°4'; of left side 102°. Left pupil much the larger. Both pupils react to light. Urine is clear, acid, and contains many granular casts, and one-fourth per cent. of albumen.

2 a.m. —Lies quite still and unconscious. Temperature, right side 99°4'; left side 100°2'.

3 a.m. —Right lower extremity moves when tickled at the sole, but not nearly so much as does the left lower extremity. Temperature, right side 98°8'; left side 100°4'.

6 a.m. —Passed water freely in bed. Bowels not open.

11 p.m. —Both pupils react. Lower extremities pit much less than they did on admission. Patellar reflex present at each knee, less at the right than at the left. Has swallowed very little, but he swallows with much greater ease than he did. Pulse 80. Respirations 40. Temperature, right side 100°6'; left side 99°8'.

Ordered—Ice. Hst. sennæ co., p. r. n. Boroglyceride 3j. in each pint of milk that he takes.

July 21. —Slept about two hours in the night. Very restless during the rest of the night. Is much more conscious this morning. Had great difficulty in swallowing last night, but this morning he opens his mouth and swallows easily, and says "No," when he has taken enough. Bowels not open. Temperature 98°8° both sides. Has swallowed hst. sennæ co., 3iss. Passed water under him. Both pupils freely react to light; the left is slightly the larger. Tongue very dry.

P.m. —Both pupils are equal and react to light.

Ordered—Enema simplex, cras mane, si opus sit.

July 22. —Much better night. Bowels open. Pulse 60, smaller volume. Respiration 80. At 9 a.m. had an epileptiform convulsion; clonic convulsions, affecting chiefly the muscles of the face, followed by coma, with puffing, stertorous respiration. Temperature, 98° right side, 99°4° left side.

Ordered—Cataplasma sinapis to the loins, to be followed by hot fomentations.

11 a.m. —Became somewhat more conscious. Temperature, right side 104°4', left side 104°2'.

3 a.m. —Was apparently quite conscious. He complained by gesture of his flannel shirt, and seemed to be satisfied when his wife told him that she would fetch him another.

5 p.m. —Respirations became greatly quickened and loudly stertorous. Had two epileptiform attacks, in the first of which he became entirely comatose, and remained so, profusely perspiring, with respirations greatly hurried, and a pulse which quickly became very weak, small, and irregularly intermittent until death, at 5.15 p.m. No post-mortem examination.

Remarks.—The symptoms presented on admission were those of ingravescent apoplexy. The heart's impulse was forcible, and the patient had some albuminuria, and his radial arteries were hard and tortuous. The onset of the symptoms was not sufficiently sudden to justify a diagnosis of embolism, and, moreover, the heart's sounds were natural. The temperature record is interesting, as serving to show how very similar the heat of the two sides of the body was. The paralysed side was at first the cooler, then it was hotter, then of the same temperature for one whole day, and about the same for two days. After death the temperature on the two sides fell at very similar rates.

Transactions of Societies.

ACADEMY OF MEDICINE IN IRELAND.

MEDICAL SECTION.

A MEETING of the Medical Section was held on Friday evening, Feb. 15, at the College of Physicians, The Registrar-General of Ireland (Dr. Grimshaw), in the Chair.

SPINAL CORD DISEASE.

Dr. NIXON read a paper on a case of primary lateral sclerosis and exhibited the patient.

Dr. J. W. MOORE pointed out that the deep reflexes were better marked on the side first affected, and on which the disease had apparently made most way. This was of some interest, as the right limb was affected more than two months before the left became implicated.

Dr. HENRY KENNEDY said there were cases on record where similar symptoms existed, and yet no lesion of the cord. Considering some of the facts, there were grounds for ascribing all the symptoms to a local cause. The late Dr. Graves had drawn attention to the fact of paraplegia occurring as the result of external causes, and that persons can get paralysis of the lower limbs from exposure to wet. The boy here being a common labourer, it was not straining a point to suppose that he had been exposed in such a way as to endanger the functions of the lower limbs. In Weir Mitchell's work there were records of a host of cases where extraordinary symptoms arose from direct injury to the nerves themselves. A Scotch medical man had given an interesting account of an individual labouring under an affection of the hand, and after death the nerves of the hand and arms were found diseased in themselves. Therefore, he would be slow to connect symptoms necessarily with the spinal cord.

Dr. NIXON, in reply, concurred with Dr. Moore that the reflexes were more marked in the limb where the paralysis commenced than in the other limb. It was difficult to conceive how anyone could adopt the view of the symptoms that existed in the boy's case being due to a peripheral form of paralysis. There were other symptoms that clearly showed the disease had a central origin. In no other way could be explained the reflex phenomena. Or, assuming there was a motor paralysis, why was there not complete extinction of the reflex, as there should be if the motor nerves were involved. He would be sorry the society accepted the view that a case like the present, where the signs of nervous lesion were of so marked an origin could be due to functional phenomenon, or phenomenon that had a mere peripheral source.

DISCUSSION ON SCARLET FEVER.

Dr. J. W. MOORE in the first place pointed out the strict obedience to the law of seasonal prevalence of scarlet fever which the present epidemic had shown. He illustrated that law by an allusion to the observations made upon the subject by the Registrar-General for England, Dr. Ballard, Dr. J. W. Tripe and himself. According to the statistics of admissions and deaths from scarlet fever patients, compiled from the register of Cork Street Hospital for ten years, 1874-83, inclusive, it appeared that of 738 patients admitted with the disease, 192 came in during the first quarter of the year, 136 during the second, 194 during the third and 216 during the fourth. The deaths, 149 in number were, similarly distributed, 38 occurring in the first quarter, 24 in the second, 31 in the third, and 56 in the fourth. The continued prevalence of so infectious a disease during the autumn and winter was no doubt due to the facilities for the spread of infection afforded by overcrowding and deficient ventilation. As regards the present outbreak, the admissions were:—April, 1883, 0; May, 8; June, 5; July, 9; August, 15; September, 23; October, 27; November, 32; and December, 26. The epidemic reached its greatest intensity about the end of October, and was now subsiding, according to the usual law. He presented a table showing the number of male and female patients, with the ages, deaths and mortality in each group. The prevailing type of the disease was scarlatina anginosa, and the mortality up to the end of January, 1884, had been 24 per cent. among males and 23·8 per cent. among females. The general mortality had so far been 23·6 per cent. Among children under 5 years of age it was particularly high, 32 per cent. among males and 35·3

per cent. among females. The chief complications were acute desquamating nephritis and renal dropsy, uræmic convulsions best treated by pilocarpin; diffuse cellulitis of the neck, followed in one instance by cancerum oris; diphtheria in one case, treated with sulphurous acid spray; rheumatism and, in a private case, phlegmasia alba dolens.

Dr. J. E. KENNY bore out Dr. Moore's statement fully as to moderate temperature favouring the development of scarlatina. Moisture was an important factor in the production and spreading the disease. Another point was the connection of scarlatina and erysipelas. In the late epidemic in August and September erysipelas became frequent, and he had a number of cases of diffuse cellulitis of an aggravated form in the North Dublin Union Workhouse Hospital, and scarlatina in the following month became epidemic in the house itself, he connected the action of the atmospheric influence and the alliance between the two diseases. The defective housing of the poor was one of the great causes of epidemics such as scarlatina; in winter time ventilation is an important factor, and that was why the epidemic reached a climax in cold weather, though it commenced in moderate temperature, he asked what was the most rapid case in which death occurred? In a child, æt. 13, he had known it to follow 36 hours after the first symptoms.

Dr. C. J. NIXON corroborated Dr. Kenny with regard to the effect of the humidity of the atmosphere influencing the spread of scarlatina, he agreed with Dr. Moore's statement as to the frequency with which epidemics of erysipelas and scarlatina run together. There was another also prevalent in scarlatina epidemics—namely, typhoid fever; and that was one of the arguments Dr. Harley used for regarding typhoid fever as abdominal scarlatina. He would be sorry to go the length of regarding the two diseases as one, only having a different locale. Another point he had no opportunity of verifying was the particular lesions found in very grave cases of scarlatina that died in a couple of days after the accession of the disease. A little girl was admitted from a house where two of her sisters had died, and she died in the Mater Misericordiae Hospital, she was unconscious with a temperature of 106° or 107°, and an exceedingly rapid pulse. She died within 24 hours after admission and within 48 hours after she got ill. On post-mortem examination, the only lesion he found was an extremely well marked condition of poecenteric. He did not, however, think that could be regarded in the smallest degree as establishing any identity between the two diseases; because in all cases of pyrexia there was an increased amount of lymphatic functions, and the spleen underwent enlargement. He did not think there was anything more remarkable than the varying symptoms in the different epidemics.

Dr. BOYLE said Bartell had referred to a malignant form of scarlatina where the throat was principally affected, as the form most complicated with nephritis.

Dr. FITZPATRICK related the case of a child whom he was called to see in consultation some years ago. It was in perfect health and was suddenly attacked with vomiting. He saw no eruption, sore throat, enlarged tonsils or any indication except prostration of the high fever, and he said the child was labouring under congestion of the brain from poisoning, and the poison he could conceive was scarlatina. The child died next morning at 7 o'clock, that was the quickest case of fatality he ever saw. A post-mortem examination was held and a slight effusion was found on the brain, while there was enormous congestion of the cerebral substance. One solitary gland was enlarged; two of the family and a lady in the house were attacked with scarlatina. He, himself, took the disease and one of his children died of it, making two deaths out of 12 cases; it afterwards transpired that the child had been taken the night before to the wake of a person who had died from scarlatina.

Dr. HENRY KENNEDY observed that in these cases of rapid course the throat was very little engaged. He had seen them several times to succumb between thirty to thirty-six hours. Within six weeks he had been called to two fatal cases which ran rapidly into coma. There was no affection of the throat, but there was evidence of congestion and the pupils of the eyes were wild-looking and exceedingly contracted. He had been cognisant of four cases of fatal hæmorrhage from the vessels in the neck giving way.

Surgeon-Major GORE mentioned the extreme rarity of scarlet fever in India, where there was such a high temperature. In five and a-half years' experience in India he reported only four cases, and these in troops coming into

the country. The disease never spread, it did not exist among the natives, whereas measles was extremely common.

Dr. J. W. MOORE in reply, said during the present epidemic they had had no very rapid case. The shortest was three days from the initial symptoms. The most rapid case of which he was ever cognisant was thirty hours. As to the period of incubation alluded to by Dr. Fitzpatrick, it appeared in his case to be only one day. He was now in the habit of speaking confidently as to the safety of those who had been exposed to the infection, if seven days had elapsed from the exposure. There was no ground for supposing that the period of latency was protracted beyond seven days; it was nominally between three and seven. With regard to the coincidence of enteric fever and scarlet fever, or (as Dr. Nixon had put it, in the words of Dr. Harley), the possible connection, he did not believe in that at all. Enteric fever and scarlet fever both arose in autumn. That explained their coincidence. Again, both were accompanied by a glandular complication, particularly in children; but the glandular complication was quite distinct. It was usually the solitary glands, in scarlet fever, that were affected, while in typhoid fever the agminate glands were. There had not been much enteric fever in Dublin. With regard to the infrequency of scarlet fever in India, Dr. Ballard considered that a higher temperature than 60° did not appear to be in itself unfavourable. For its complete development it was necessary that the condition of the atmosphere should not exceed 86° or be much less than 74°. In India the temperature was exceedingly high unless at the rainy season, and hence the infrequency of the disease for the reason he had mentioned. The coincidence of erysipelas and scarlet fever was not a new discovery, having been alluded to by Dr. Graves in the terrible epidemics of 1803-32 in Dublin, and James Cusack had also placed the same observation on record. Lastly, it was worth remarking that small-pox and scarlet fever were closely related as regards their times of prevalence, and there seemed to be a strange susceptibility to the poisoning of scarlet fever by those who were recovering from small-pox, and the converse was equally true. The same observation was not at all applicable in common or typhus fever.

The CHAIRMAN remarked as to the parallelism which Dr. Nixon seemed to think existed between scarlatina and enteric fever, that so far as the present epidemic was concerned there was no parallel whatever. During the fifty-two weeks of 1883, enteric fever was constantly prevalent, whereas, in the early part of the year the death-rate from scarlatina was returned in most of the columns, blank. Six weeks elapsed without a single death from scarlatina being registered, and then only one. In Dublin the epidemic had been as nothing compared with what had occurred in Belfast, where during 1883, the deaths from scarlatina numbered 353 against 179 in Dublin, and Belfast district was not two-thirds the size of Dublin district. It was one of the most formidable epidemics of which he had ever heard. He had a table for ten years, setting out the most important zymotic diseases for each province, and it appeared that scarlatina and several other diseases had regularly ranged throughout the country. It was highest in Leinster in 1874, in Munster in 1872, and in Ulster in 1875. This moving about was a feature common to epidemics, and showed the importance to take proper measures to prevent the spread of disease by notification. Nearly all the diseases they got from Liverpool, and it was important that the advent of a disease should be noted from Liverpool just as from one part of Dublin to another. The liability of small-pox patients to get scarlatina arose from the great diffuseness of the poison of scarlatina rather than any predisposing liability of the patients themselves.

The section then adjourned.

FOR the Chair of Pathology in the University of Cambridge the following gentlemen are candidates:—Prof. Hamilton, of Aberdeen; Dr. Joseph Coats, of Glasgow; Dr. Woodhead, of Edinburgh; Dr. Roy, of the Brown Institution; and Dr. Creighton, formerly Demonstrator of Anatomy at Cambridge.

LIVERPOOL MEDICAL INSTITUTION.

THURSDAY, MARCH 13TH.

Dr. MACFIE CAMPBELL, Vice-President, in the Chair.

Dr. ARCHER exhibited an interesting specimen of
MITRAL STENOSIS.

It was the heart of a male, *æt.* 27, who had had an attack of acute rheumatism fifteen years previously. There existed the well-known signs of contraction of the mitral orifice, that is to say, there was a presystolic murmur and thrill situated slightly internal to situation of apex beat, also a duplication of second sound over the pulmonary area. The area of cardiac dulness was increased. He suffered at times from severe attacks of dyspnoea, and from congestion of the lungs. From time to time he apparently derived much benefit from treatment. The cause of death was the onset of a sudden attack of pulmonary oedema. Some time before the fatal termination, the presystolic bruit had become inaudible. Dr. Archer mentioned that this was a symptom of bad omen, showing that the heart was losing its compensatory powers. At the post-mortem, there was found extensive pleural adhesions, and also pleuro-pericardial adhesions. The pericardium was adherent over the anterior surface (right ventricle) of the heart. The heart was rather globular in shape, weighing between sixteen and seventeen ounces. The left auricle was dilated, and its walls somewhat hypertrophied. On looking at the mitral opening from the auricle, it was represented by a narrow button-hole like slit, surrounded by a rough, thick, bony ring. It had much the appearance of a diseased and indurated os uteri. The mitral valves were thickened, rough, noduled, and fused together. The right cavities were dilated, and there were traces of commencing disease at the tricuspid valves, they were thickened, and minute vegetations were visible along the margin of one of them. The lungs were congested and oedematous.

EXTRAORDINARY FOREIGN BODY IN THE NOSE.

Mr. RUSHTON PARKER showed a gun breech and bolt removed from the nose after five years. The patient was a Welsh farmer, *æt.* 26, who was brought to him suffering from a fetid discharge from the nostrils and from the upper jaw inside the lip, with the history of a gun accident five years previously. The discharge was supposed to proceed from a necrosed bone, and Mr. Parker at once made arrangements for removing the diseased portions, the patient taking lodgings in Liverpool for the purpose. In order to avoid disfiguration, the opening between the lip and jaw was enlarged and, after considerable violent traction, a loose body was removed, which proved to be a breech and bolt of a single barrelled fowling piece, which had remained embedded ever since the gun accident five years before. The bleeding was profuse, but was allayed by hot water. The weight of the metal removed was 3½ ounces, and the length about 2½ inches. He mentioned that a somewhat similar case had been noted by Mr. Lawson. He then showed some specimens of comparative pathology, and afterwards a simple mammary cyst that was of interest clinically, as it was almost solid and so hard as to be scarcely distinguishable before removal from cancer.

Mr. DAMER HARRISON then showed a boy from whom he had removed a portion of os calcis for destruction of soft tissue over the heel; after which he exhibited a patient who had sustained a fracture of the spine between the second and third lumbar vertebrae. This case was noticeable from a curious area of anaesthesia on each thigh, and from the fact that when bladder trouble arose an opening was made into the bladder for the purpose of drainage, this line of procedure being followed by very happy results.

Mr. REGINALD HARRISON remarked on this case that Mr. Damer Harrison had suggested and illustrated a line of practice. In paralysis after such injuries it was usually the bladder complication that killed—the cystitis, sloughing, ammoniacal urine—the patient was killed by his own excretions. We should do good service by laying the bladder freely open and letting the patient drain. This was far better than passing the catheter six times a day.

Dr. GREVES asked whether there was any affection of the rectum simultaneously with that of the bladder. Also if there was any acute muscular atrophy of the legs, and whether the anaesthesia was quite limited to the area described. He quoted a case which proved the truth of

Charcot's recent observations, which proved that regeneration of a diseased cord might take place, and pointed out that the presence of acute bed sores and bladder trouble in Mr. Harrison's case showed that there was serious mischief either in the central part of the lumbar cord, or complete obliteration by pressure of the transmitting power of the nerves of the cord equina.

Mr. REGINALD HARRISON then read his case of
CYSTOTOMY FOR RUPTURED BLADDER,
which will be found on page 295.

Dr. CAMPBELL related the particulars of a similar case that had been treated in the Liverpool Northern Hospital, under the care of Mr. Puzey, and which ended favourably.

Drs. Alexander and Imlach also spoke; after which Mr. Harrison replied.

Dr. GLYNN then related some particulars relating to a case of

OPHTHALMOPLÉGIA EXTERNA,

a disease which was of sufficient rarity to be of interest. The patient was a young man (patient exhibited) suffering from no very positive symptoms, except vomiting and hiccough, and it was also noteworthy that he had become worse under treatment. As there was a syphilitic history, the patient had been treated by mercury and large doses of iodide of potassium. The prognosis in these cases was unfavourable. The affection was interesting from its association with bulbar paralysis, neighbouring parts of the medulla being affected in the two diseases. The pupils were generally sluggish, and there was no ataxia.

SUPPURATIVE OSTITIS OF THE FEMUR.

Mr. PAUL showed the femur from a girl, *set.* 12, who had been subjected to amputation at the hip-joint for this condition, following excision of the hip. The patient was some time under observation with hip disease before the excision was performed. After the operation she progressed fairly well for a time. Then the whole thigh became gradually very much swollen, and a profuse discharge of pus commenced with the formation of numerous sinuses from the hip to the knee. Exploration of these sinuses showed the periosteum was not removed from the bone, and that there was no large sequestrum anywhere that could be removed. After nine months profuse suppuration, when the child was almost exhausted, the parents permitted amputation at the hip-joint, which was rapidly followed by recovery. The bone was a specimen of considerable interest and rarity. The whole of the old shaft had been removed by suppuration, and replaced by the gradual formation of a delicate loose new bone, of scarcely greater diameter than the original shaft. Here and there in the meshes of the new bone small sequestra of the old one still remained. The medullary cavity was not differentiated. The lower epiphysis was simply in an extreme condition of rarefying ostitis. Mr. Paul said that inflammation of the central portion of the bone produced exactly analogous conditions to inflammation of the cortex and periosteum, and showed several specimens in illustration. Acute inflammation led to septic poisoning or central necrosis as after amputation; while a lesser intensity produced rarefying or suppurative changes in delicate subjects, and osteoplastic changes with the formation of new bone in the medullary cavity in more robust constitutions.

THE triennial dinner of the Jews' Hospital, held last Thursday, has, so far, produced the largest subscription list of any of the London festivals. This was held under the presidency of the Lord Mayor, when a sum of £4,200 was subscribed in the room. The hospital is in connection with the Orphan Asylum, and both have done good and useful work among the distressed portion of the Jewish community.

A FIRE broke out at Hope Hospital, Salford, on Saturday night, and was not extinguished for six hours. The damage done to the building is very heavy, but, fortunately, all the patients were removed to a place of safety without injury.

The General Medical Council.

THIRTY-FIFTH SESSION, 1884.

LAST Tuesday week the members of the General Medical Council met in London, according to annual custom; but considerable haziness appeared to pervade the minds of many as to the objects for which they were called together, now that the Government have taken medical education and medical affairs generally into their own hands. This view of uncertainty of tenure, of cramped powers and hampered intentions pervaded the President's speech in opening the session. In this speech Dr. Acland gave a brief outline of the work before the Council, and of the objects of the Medical Bill, the main principles of which were four—viz.: (1) To ensure one final pass examination in each branch of the Kingdom, all three being reasonably uniform. (2) To appoint three medical boards which shall regulate the chief educational details, in the place of the branch councils. (3) To alter the mode of appointment of the supreme General Council. (4) To amend or enact divers clauses which experience has shown to need revision or addition. He referred to two or three cases of removal from the Register for infamous conduct, and to the action of the committee on unqualified assistants. He naively suggested that the Council might consider whether it could not reform itself, by the rectification of certain ambiguities which have from time to time been found; concluding his address by mentioning that, as his term of office expired this summer, the fate of the Bill would probably be known.

The Council this year is constituted as when it last met, with the exception of Professor Struthers of Aberdeen, who took his seat this session for the first time as the representative of the Universities of Edinburgh and Aberdeen, *vice* Prof. Turner.

THE EXECUTIVE COMMITTEE.

The Executive Committee was then chosen, and the following members were reappointed: Dr. Acland (President), Sir Henry Pitman, Mr. Simon, Dr. Haldane, Dr. Humphry, Dr. Quain, and Dr. Aquilla Smith.

PASS AND PLUCK STATISTICS.

A table showing the results of professional examinations held in 1883 for qualifications granted under the Medical Act by the bodies named in Schedule A was laid before the Council.

Dr. AQUILLA SMITH, referring to the table prepared by him, said it contained some interesting facts, to which he desired to call attention, with reference to the percentages of rejections at the final examinations by the different bodies. He had compared the rejections in 1883 with those in 1867, with the following result:—

Percentage of Rejections in 1883 and 1867.

	1883	1867.
Royal College of Physicians, London ...	20.0	11.2
Royal College of Physicians, Edinburgh ...	29.8	19.4
King and Queen's College, Dublin ...	19.4	19.4
Royal College of Surgeons, England ...	36.7	12.0
Royal College of Surgeons, Edinburgh...	47.7	17.5
Royal College of Surgeons, Ireland ...	25.3	15.8

Conjoint Boards.

	1883.	1867.
Royal College of Phys. and Surg. Edin.	47.6	20.4
Roy. Coll. of Phys. Ed. & Glas. Faculty	42.8	14.7
Glasgow Faculty	43.6	44.0

In the case of the following bodies the rejected exceeded the passed:—

	Rejected.	Passed.
University of London	126	116
Royal College of Surgeons, Edinburgh ...	120	111
Faculty of Glasgow	54	49
Roy. Coll. of Surg. Irel. (New Scheme)...	100	17
Ditto ditto (Old Scheme)...	118	126

Taking into account these large proportions of rejections at primary examinations, and also the large proportion of candidates rejected by the College of Preceptors, they had unmistakable evidence of the fact that there was a great defect in the primary education of young men entering the medical profession. The matter was one which ought to engage the serious consideration of the Council, with a view of instituting an improved curriculum of education. No student ought to be admitted into any medical school

without having obtained a satisfactory certificate of preliminary education. At present young medical students were often not better educated than those who had situations in the Custom House or in the Post Office. A well-devised system of elementary education for the students would, he believed, produce very satisfactory results, and prevent many abuses. He did not propose to make any motion on the subject, but he hoped it would not be overlooked by the Council.

Mr. MACNAMARA thought there must be some error in the figures cited by Dr. Aquilla Smith with regard to the licence of the Royal College of Surgeons, Ireland (new scheme). The statement was that 100 were rejected and 17 passed. He doubted if more than 17 students altogether had gone in under the new scheme.

CANDIDATES UNDER THE EXCEPTIONAL CLAUSE.

A table showing the number of exceptional cases occurring in 1883 under Clause 20 of the Council's Recommendations on Education and Examination, with a statement of the action taken thereon by the licensing bodies, was laid before the Council.

Mr. MACNAMARA said he thought it would be gratifying to the Council to know that the College of Surgeons, Ireland, had cordially accepted its recommendations, and that "exceptional cases" had been remitted at once to the branch council for consideration, as required by the General Council. He observed, however, that the College of Physicians of London and the College of Surgeons, England, had had a number of such exceptional cases, but had not referred them to the branch council in England.

Mr. MARSHALL said that the cases in question had been very carefully considered by the Council of the College of Surgeons, and the authority of different examining bodies had been closely investigated. The candidates were from Indian, Colonial, or foreign universities and colleges, and the Council had exercised its power with extreme care.

Sir HENRY PITMAN said that the Council had resolved that such exceptions might properly be allowed in case of any graduate in medicine of an Indian, a Colonial, or a foreign university, or of any student who, having completed the full time required by the Council, and having given satisfactory evidence of general education, should have spent the whole or three-quarters of that period at an Indian, a Colonial or a foreign university.

Mr. SIMON said that the licensing bodies had been requested to communicate to the Council (not to the branch councils) annually a statement of the action taken by them in respect of such exceptional cases. The returns laid before the Council were in accordance with that request. He desired to express the pleasure with which he had heard of the action taken by the Royal College of Ireland in the matter.

AMERICAN AND COLONIAL EXAMINATIONS.

A communication was read from the Provincial Board of Nova Scotia enclosing extracts from the Medical Act of Nova Scotia, and informing the Council that the subject of elementary mechanics of solids and fluids had been added to the subjects in the compulsory list.

Sir HENRY PITMAN moved that the communication be received and entered on the minutes.

Dr. HAUGHTON said he had satisfied himself by personal visits that the elementary examinations of many of the American and Canadian bodies were not at all satisfactory. Those in Australia, New Zealand, and Ceylon were of a much better character. He argued that it was not necessary to enter the letter from that Board on the minutes, and that it should be simply entered as having been read, no action being taken upon it.

This was ultimately agreed to by the Council.

PERSONATION AT EXAMINATIONS.

The following report was received from the Executive Committee with reference to the provisions taken to ensure the impossibility of personation at the examinations of the several bodies, the certificates of which were accepted by the Council as satisfactory evidence of preliminary examination.

"In some instances (the Universities of Oxford, Cambridge, Durham, Glasgow, St. Andrews, Victoria, Aberdeen, and Dublin), the students are resident in the universities, and are personally known to the examiners or others con-

noted with the examinations, which is regarded as affording sufficient security against personation. In Aberdeen, however, there is the additional precaution of comparing the handwriting of the exercises with that on a small schedule filled up beforehand by the candidate; and in this way two instances of personation were detected. In other instances (the Oxford and Cambridge School Board Examinations, the Durham and St. Andrews Local Examinations, and the Local Examinations of the College of Preceptors), the examinations are at the schools, or the schoolmasters or teachers are present, or are responsible that the candidates are *bond-fide* pupils in their several schools; and there is, in addition, the security afforded by the signatures of the candidates previously given in. In the third class of cases (the Examinations of Colleges of Physicians and Surgeons of Edinburgh, the Durham Medical Registration Examination, the University of London Matriculation, the Glasgow Local and Preliminary Examinations, the Examination of the Apothecaries' Society of London, of the Apothecaries' Hall of Ireland, the Assistant Commissioners of Intermediate Education in Ireland, the Royal College of Surgeons of Edinburgh, the Examination of Private Students at the College of Preceptors, and Oxford Local Examinations), the candidate previous to the examination fills up a form with his signature, the handwriting of which may be compared with that of his answers. In the case of the Local Examinations, moreover, the candidates are usually from schools or centres where they are known. In the University of Edinburgh the signatures of candidates are preserved, which can be compared with their names at subsequent examinations. The Faculty of Physicians and Surgeons of Glasgow, after full discussion, with a view of devising some effective check, forced upon them by the occurrence of two cases of personation at their examinations, came to the conclusion 'that the most effectual means of deterring from such a nefarious practice will be found to be the prosecution of the delinquents in every case in which the evidence warrants it.' The Royal College of Surgeons in Ireland has not adopted any special means, but appreciates the necessity for the adoption of precautions. The Civil Service Commissioners say that they take such measures as they deem necessary. The committee recommend the Council to suggest to all examining authorities that, except so far as they may have in use other and better means of identifying candidates, precautions as follows should be taken:—1. That each person desiring to present himself for examination by any examining authority should be required to make previous application to the authority in a prescribed form, signing his name to the application, and having his signature attested in a way which would suffice for its authentication. 2. That each examining authority should keep a signature book for the candidates who present themselves for examination, each of whom should be required to sign his name in the book in the presence of an officer of the authority." The committee recommend that if this Report be approved, a copy of it, with the "answers," be sent to each of the several bodies, the certificates of which are accepted by the Council as satisfactory evidence of preliminary examination.

The two recommendations proposed by the committee in the foregoing report were then entered on the minutes, and the Council adjourned.

SECOND DAY.—WEDNESDAY, MARCH 26TH.

REMOVALS FROM THE REGISTER FOR INFAMOUS CONDUCT.

The first business was the reception of a report by the solicitor of the Council on the case of Daniel Murray O'Hara, referred to him by the Executive Committee, by whom he had been instructed to take such steps as might be necessary to ascertain the identity of Daniel Murray O'Hara, and to bring his case before the Council, both in respect of his being the person he represents himself to be, and also in respect of a letter received from him in October, 1883, by Dr. Heard, registrar of the Irish Branch Council.

In the first case there was a confliction of identity and name, the person charged being O'Hare or O'Hara. A medical agent who gave evidence swore positively that it was one and the same individual, and that he had seen him that morning. The solicitor to the said Dr. O'Hara, on the other hand, attended and produced a medical certificate, dated March 24th, certifying that Dr. O'Hara of Prescott

had had a very severe attack of angina pectoris, and was totally unfit to travel.

Dr. HAUGHTON stated that he had compared some of the letters written by Dr. O'Hara and Dr. O'Hare, and the handwritings did not appear to him to be identical; but he attached but little importance to that circumstance after the positive evidence of identity given by the medical agent.

Sir HENRY PITMAN said it would be an important link in the evidence if they had before them the diplomas actually held by Dr. O'Hara. It was true, however, that they would not establish his identity, as he might have surreptitiously obtained them from another person.

Mr. BURRELL, law adviser to the Council, stated that in January, 1859, D. M. O'Hara was registered as M.D. of the Queen's University of Ireland, and Member of the College of Surgeons, England, and that in December, 1858, O. P. O'Hare was registered with the same qualifications.

After some deliberation in private.

The PRESIDENT announced that the Council had come to the conclusion to adjourn the inquiry into Dr. O'Hara's case for further information.

The Council received a report from the Dental Committee with reference to the cases of J. P. Murray and A. A. Sadgrove, whose names had been removed from the Medical Register for unprofessional conduct but remained on the Dentist's Register. The facts stated by the committee were as follows:—

1. *Re James Patrick Murray.*—That James Patrick Murray was concerned with others in kidnapping some natives of the Fiji Islands, in consequence of which an outbreak occurred on board his vessel, in which several of the kidnapped islanders were killed. That in consequence of this offence, the King and Queen's College of Physicians of Ireland and the Royal College of Surgeons of Ireland struck his name off the respective rolls of Licentiates of those Colleges. That James Patrick Murray's name has been removed from the Medical Register by order of the General Medical Council in conformity with Section 28 of the Medical Act.

2. *Re Arthur Augustus Sadgrove.*—That Arthur Augustus Sadgrove, being registered only as a "Licentiate of the Apothecaries' Hall of Dublin," falsely and fraudulently held himself out to be also a Licentiate of the Royal College of Physicians of London and a Licentiate of the Royal College of Surgeons of Edinburgh, thereby endeavouring to induce persons to believe that he was possessed of more or greater qualifications than was the fact. That the Royal College of Physicians of London had previously proceeded against Arthur Augustus Sadgrove, at Wallingford, for professing to be a physician, for which he was fined £5, and costs £5. That a prosecution by the Faculty of Physicians and Surgeons of Glasgow against Arthur Augustus Sadgrove for unlawfully and wilfully uttering a forged document, purporting to be a diploma of that Faculty and obtaining money by false pretences, failed on technical grounds. That Arthur Augustus Sadgrove's name has been removed by order of the General Medical Council from the Medical Register.

Both of the accused having been summoned to appear before the Council (Mr. Sadgrove alone appearing), the President, after private deliberation of the Council, announced that, as it had been proved to the satisfaction of the General Medical Council that these two persons had been guilty of infamous conduct in a professional respect, the Council does, by this order in writing, direct their names to be erased from the Dentist's Register, and it orders the registrar to erase their names accordingly.

Dr. STRUTHERS then moved, "That the various examining bodies be requested to intimate in future to the General Medical Council all cases of personation." He said he did not know that the Council could enforce information of such cases being given to the twenty licensing bodies, and therefore the simple plan was to ask that information should be given to headquarters.

Dr. PYLE seconded the motion.

Dr. HAUGHTON said he presumed the object was that the Council should send the names to all the examining bodies, and he should suggest the addition of the words, "with a view to their being communicated to the examining bodies recognised by the Council."

The addition having been accepted by the mover and seconder, the motion as amended was agreed to.

PRELIMINARY EXAMINATION.

The following communication was received from the College of Preceptors, and ordered to be entered on the minutes, the thanks of the Council being accorded for the same:—

"42 Queen Square, London, W.C.

"October 11th, 1883.

DEAR SIR,—I beg to submit, for your information, a statement of the results of the Preliminary Examination for Medical Students and others, held by this College on the 4th to 6th of September last. The number of candidates examined was 264, of whom 193 sat at the London centre, 20 at Bristol, 15 at Birmingham, 15 at Leeds, and 21 at Liverpool. Of the total number examined, 82 (or rather less than one-third) obtained certificates qualifying for registration as medical students, and one candidate passed in mechanics as a separate subject. Of the 182 who failed to obtain qualifying certificates, 20 passed in all the obligatory subjects, but did not obtain the minimum total of marks required for a place in the second division of the second class, as required by the Medical Council. Of the remaining 162 rejected candidates, 61 failed in one obligatory subject, 25 in two, 26 in three, and 38 in four (and more) obligatory subjects. Thirty-two candidates were reported for defective spelling, but only one candidate was disqualified on that account alone.

I am, dear sir, yours faithfully,

C. R. HODGSON, Secretary.

The Council then adjourned.

THIRD DAY.—THURSDAY, MARCH 27TH.

DENTAL BUSINESS.

A Table, showing results of professional examinations held in 1883 for qualifications granted under the Dentists' Act, was received, and resolved to be entered on the minutes.

THE LATE DR. ALLEN THOMSON.

The PRESIDENT mentioned that the remains of Dr. A. Thomson would leave Euston Station at 3 o'clock, and it was resolved that three members, one each for England, Ireland, and Scotland (Prof. Marshall, Dr. Struthers, and Dr. Aquila Smith) should represent the Council on the occasion.

CONJOINT SCHEMES.

On a motion to receive letters from the Royal Colleges of Physicians and Surgeons, advising the Council of their withdrawal from a proposed scheme of conjoint examination,

Dr. PYLE having referred to previous discussion of the same subject,

Dr. QUAIN urged that the Council should have further information respecting the non-fulfilment of the scheme carefully considered by the Council several years ago. Had this been done, the existing need for legislation would never have arisen.

Dr. AQUILLA SMITH thought it would be improper to demand any explanation of the kind required.

The PRESIDENT pointed out that the motion was to receive and enter on the minutes the letters referred to. Dr. Quain might then very properly pursue his inquiry by giving notice of a question.

Rev. Dr. HAUGHTON agreed with Dr. Quain that before agreeing to accept the letters an explanation should be given by the two Colleges of the reason for their non-carrying out of the arrangement.

Sir H. PITMAN took the opposite view.

Mr. MACNAMARA supported Dr. Quain.

Prof. HAUGHTON moved that the reception of the minutes be postponed till the following day.

After considerable further discussion, in which Dr. Fergus, Mr. Simon, Dr. Quain, Dr. Aquilla Smith, &c., took part, the amendment was carried.

UNQUALIFIED ASSISTANTS.

Two letters, from the Registrar-General and the Lord President of the Council respectively, in which acknowledgment of the Council's resolutions on the question of unqualified assistants was made, were next read, and a motion that they be received and entered on the minutes was carried. In reply to Dr. Chambers,

The PRESIDENT said that no clause would be introduced into the new Medical Bill dealing with the question of unqualified practices. The Registrar-General, however, having suggested that the Council should embody its views in the form of a

proposed new clause, it would be for it to consider this question.

The motion to receive the letters was carried.

FINANCE.

The report of the Finance Committee was presented and received. From it it appears that the income of the General and Branch Councils for the year 1883 (ending December 31, 1883) has been £7,945 7s. 6d., an amount which exceeds by £780 19s. 7d. the income for the year 1882. The expenditure during the year 1883 has been £4,451 6s. 6d., which is less than the expenditure of 1882 by £369 3s. 7d., showing an excess of income over expenditure for the year 1883 amounting to £3,494 1s. The excess of income over expenditure for the previous year, 1882, was £2,843 17s. 10d.

THE PHARMACOPŒIA COMMITTEE.

The report of the Pharmacopœia Committee was received and entered on the minutes; it declares that since the last meeting of the Council, in April, 1883, the arrangements for the preparation of the next edition of the Pharmacopœia have been continuous. The sub-committee has met on four occasions, and has been in communication with the editors personally, and by written reports. A memorandum has been forwarded by the Registrar to the several medical authorities mentioned in the Medical Act, to various pharmaceutical bodies, and to several gentlemen holding prominent positions as practical pharmacists and manufacturing chemists. Answers in reply to this communication have been received from the Royal College of Physicians of London (provisional), the Royal College of Surgeons of England, the Apothecaries' Society of London, the Royal College of Physicians of Edinburgh (provisional), the Royal College of Surgeons of Edinburgh, the King and Queen's College of Physicians in Ireland, and the Apothecaries Hall of Ireland.

These communications from the several medical authorities contain many valuable suggestions, for which the thanks of the Council are due, and communications have also been received from several pharmacists and manufacturing chemists.

PRELIMINARY EXAMINATION.

The question of mechanics as a subject of preliminary examination having been considered by the Preliminary Examination Committee, after being found to be not usually a part of such examination, this Committee reported against discussion of the subject until it is settled what fate will befall the Medical Bill. Should this not pass into law, then in the opinion of the Committee, the Council should early take the matter into full consideration, the fact being that under existing relations students become registered without fulfilling the Council's requirements in respect to mechanics.

Sir H. PITMAN having moved that the report be received, and explained the circumstances that gave rise to it,

Rev. Dr. HAUGHTON referred to previous discussion on the subject at the Council, and urged the importance of effecting some alteration in the requirements and standard in respect to hydrostatics and mechanics. He thought the whole question of preliminary examination should be fully considered in Council, and not a single subject. He advised simply receiving the report and deferring further action for a time.

Mr. MACNAMARA said some of the students at the R.C.S.I. did pass in mechanics, and some did not, prior to presenting themselves for the first college examination. All who had not passed in these subjects, we specially examined in them at the first professional.

Mr. SIMON thought the regulation of the Council should be literally carried out, and that every student who has not passed in the subjects should be required to do so at some time before registration.

Dr. MATTHEWS DUNCAN deprecated the suggestion that the Council was moribund, and should therefore defer to take action pending the decision on the new Medical Bill.

The President also considered that it was the business of the Council to continue steadily on with its proper work until it ceases to exist; and he did not think that any reason for deferring the subject in hand could be found.

Dr. MATTHEWS DUNCAN thought physics the most important of all preliminary subjects.

Dr. STOREAR moved that, henceforth, no student should be registered unless he shall have passed in all the subjects of preliminary examination, including mechanics.

Dr. PETTIGREW concurred.

Dr. HALDANE considered that preliminary examination was pitched at much too high a standard. It was better for students to know a few things well, than to have a smattering of many. The whole subject demanded revision.

Dr. PETTIGREW urged the Council to refrain from action that would lead to over-educational strain on students.

The REGISTRAR OF THE COUNCIL, by request of the President, stated that the Students' Register for 1884 contained a special column for entries showing what students have passed in elementary mechanics. But there was much difficulty experienced in obtaining the necessary information. No English students gave such evidence of examination, nor, up to the present time, any Irish or Scotch student.

Mr. MACNAMARA said that the Irish schools did not afford information on this point, especially, because there was no knowledge that such information was required. The College of Surgeons issued only a general certificate of preliminary examination, in which no special note was made referring to mechanics.

Mr. SIMON strongly insisted on the absolute importance of a knowledge of physics to medical men of all classes, and moved that the Registrar should notify to inquirers that the regulation referring to mechanics as a subject of preliminary examination should be enforced.

Rev. Dr. HAUGHTON seconded the motion and moved the adjournment of the debate on preliminary education to a subsequent hour.

FOURTH DAY.—FRIDAY, MARCH 28TH.

THE CASE OF MR. BASS SMITH.

AFTER secret deliberation on the petition for restoration to the Register, made by Mr. Bass Smith, the Council granted the petitioner's prayer.

CONJOINT EXAMINATION.

On the resumption of the adjourned debate on the letters of the Royal Colleges of Physicians and Surgeons of London, announcing their intention to withdraw from the scheme for conjoint examination approved by the Council,

Rev. Dr. HAUGHTON moved to obtain information as to why the arrangement in question had never been carried out.

Sir H. PITMAN took exception to the action of certain members of the Council in raising discussion on the motion for receiving the letters addressed by the two Colleges to the Council, and which discussion had reference to the non-compliance on the part of the Colleges with the approved recommendations of the Council. He contended that it was a simple act of courtesy on the part of the Colleges to send their letters, the reception of which by the Council was not of the nature that it ought to have seen. He moved that the letters be entered on the minutes.

Prof. MARSHALL seconded the motion, and explained that he had no power to give an answer to the question why his College withdrew. If it required to know, the Council should make official application for the information, and as well, of the reason why the scheme had not been adopted. The Council should apply to all the seven bodies interested.

The motion having been carried,

Rev. Dr. HAUGHTON again moved "That this Council having been informed, by the letter from the Royal College of Surgeons, that the scheme approved and sanctioned by the General Medical Council has never come into operation, desires to know if this statement be correct, and, if so, why such scheme has not come into operation." He said that he was influenced in this by the fact that the Irish bodies had acted on the suggestions of the Council, and had drawn up a scheme for conjoint examination, but had waited to see how the English scheme worked before putting it in action, and waited in vain.

Dr. QUAIN seconded the motion, and said this was the first intimation officially received that the English conjoint scheme was not in operation; and it was perfectly reasonable to seek to know why this was so. He thought the two bodies would do well to withdraw their withdrawal. The London University certainly had not withdrawn from the scheme.

Mr. SIMON thought that the action of the two Royal Colleges would have the effect of inevitably terminating the scheme for conjoint examination in England.

Prof. STRUTHERS expressed a brief satisfaction at the action of the Colleges in withdrawing from the scheme. He pre-

sumed, however, that this did not indicate that the scheme had in any way fallen through from weakness. In Scotland there was a general disapproval of the conjoint schemes, and it was a satisfaction to Scotchmen to find Englishmen agreed also that combination between Corporations alone, and not between Universities, was not feasible.

IMPROPER CONDUCT.

The case of Michael Healey, a practitioner of Liverpool, whom the Medical Defence Association of that city accused of dishonourable practice by associating himself in partnership with a notorious quack, was next inquired into. Healey did not answer the summons to appear before the Council, and the Council's solicitor then read several letters bearing on the case. One of them, from the Defence Association, related that Healey died at Christmas last, but continued that the quack in question was now in partnership with another registered medical man, and suggested further inquiries on the part of Council, which, it was the solicitor's advice, should be followed.

Strangers were then directed to withdraw, and on being readmitted,

The PRESIDENT announced that the consideration of the case had been adjourned.

CONJOINT EXAMINATION.

Mr. MACNAMARA, renewing discussion on this subject, remarked that inquiry into the subject was most important. It might be thought the relinquishment of the scheme might have been designed to facilitate the passing of the Medical Bill, as existence of such a scheme would be a powerful argument against the need of such a Bill. As the Bill extinguished the only opponent of the two colleges, viz., the Apothecaries' Society, it might be said they were acting with a view to aid the passage of the measure, and he urged the representatives of the two Colleges to "make a clean breast" of their reason for acting as they had done.

Dr. HUMPHRY felt compelled to speak after the remarks of Prof. Struthers and Mr. Macnamara. Having been more than anyone else associated with the growth of the conjoint scheme in question, he was possibly better than anyone acquainted with its aims and intentions. The scheme was devised and perfected by all the English bodies in conjunction, and they had fully intended to carry it out. If, as Dr. Struthers said, England was at fault, the fault lay at Scotland's door. It was felt unwise to carry it out in England unless it was likely to be carried out in each of the other divisions, the scheme having been intended to be carried out in all three parts of the Kingdom. Prof. Humphry thought it would have been wiser had England carried out the scheme. Mr. Macnamara's remarks had not a shadow of foundation. England hesitated to go on with the scheme while Scotland held back, lest there should be an increased emigration of English students to the easier examinations of Scotland, in case the conjoint arrangement had obtained.

Prof. MARSHALL explained that the Royal College of Surgeons had made no public announcement of conjoint examination, although all arrangements had been made to that end. Action was delayed by the delay of the Scotch division of the Kingdom in proceeding with a conjoint scheme, and a resolution of the College had declared the impossibility of carrying out the scheme until it was adopted in all three divisions of the Kingdom, as otherwise an unfair competition would be perpetuated. The appointment of the Royal Commission and impending legislation served further to create delay. In these circumstances the two Colleges had engaged to create a conjoint examination by co-operation, but this had been deferred lest it might be said that it was designed to obstruct legislation. But if Government should fail in settling the question of reform, it would then remain for the Colleges to unite in forming a combination to carry out the scheme's object.

Dr. HAUGHTON expressed himself satisfied with the explanations afforded. He thought it was a great evil the scheme had not been carried out in the three divisions of the Kingdom.

Mr. TRALE thought the discussion would strengthen the proposals for conjoint schemes should the Medical Bill fail to pass the House of Commons.

Dr. SCOTT ORR alluded to the difficulty that was experienced in formulating a conjoint scheme for Scotland.

Dr. HAUGHTON asked permission to withdraw his motion.

The PRESIDENT alluded to the high importance of this

discussion. Fourteen years ago he endeavoured to promote a conjoint examination scheme. At more than 70 meetings, extending over four years, he advocated such a scheme. The Council had recognised the evil of many examining boards, and that a reduction of their number must either voluntarily or by law be made. He felt that the matter demanded action, and that the opinions of politicians and others should not influence the proceedings of the Corporations in this respect. The state of the existing political atmosphere was too uncertain to admit them to place reliance on legislative action in producing what they wished; and the difficulties under which students labour demanded that something should be done for their relief, and such a means was, he urged, to be found in a conjoint scheme of examination.

The motion was then withdrawn.

DEATH OF THE DUKE OF ALBANY.

In a few words, and under the influence of deep emotion, the PRESIDENT informed the Council of the death of the Duke of Albany, which occurred suddenly at Cannes.

PRELIMINARY EXAMINATIONS.

The report of the Preliminary Examination Committee was read and adopted.

Mr. SIMON having moved that the Registrar intimate the Council's desire to have its resolution as to mechanics duly observed,

Rev. Dr. HAUGHTON pointed out that the requirements of the Council were hardly comprehended by the members; at Dublin all students were examined in elementary physics, and went through three courses of instructions in them, and it was in these subjects the Council now sought to examine all its candidates for registration as students. He thought the whole subject of preliminary education ought to be fully discussed, with a view to limiting the area of the subjects to be brought up, so that a better knowledge of them should be obtained.

Dr. PETTIGREW deprecated putting forward any part of the preliminary examination into the professional examination.

Mr. TRALE thought the preliminary education of students was inefficient.

The motion was carried.

A somewhat lengthy discussion next occurred on the question of permitting the omission of the subjects of geography and history from the Oxford and Cambridge Schools Board Examination, as by the regulations of the Council students must be examined in these subjects. The request to this effect was finally withdrawn, and in the course of the debate leading to it a frequent opinion was expressed that the whole scheme of preliminary education would have to engage the attention of the Council at no distant date.

FIFTH DAY.—SATURDAY, MARCH 29TH.

THE LATE DUKE OF ALBANY.

The PRESIDENT read a draft letter of condolence to be forwarded from the Council to Her Majesty the Queen, and which was then approved, and ordered to be engrossed for subsequent signature by each member.

THE CASE OF O'HARA.

On resumption of adjourned consideration of the case of O'Hara, the Solicitor to the Council read a letter from O'Hara asking for an adjournment of his case on the ground that he desired to submit his defence in person, with necessary documents and witnesses. In this letter O'Hara denied that he had been in London during the week, while evidence that this was not the case had been laid before the Council. Several witnesses were next examined before the Council, by whose statements it was proved that the facts instanced against O'Hara were well founded. Mr. Wynne had engaged a person calling himself Owen Patrick O'Hara as an assistant. Some time afterwards a death certificate signed by O'Hara was returned by the Registrar, because no one of that name was on the Register, and subsequently to this the name of Daniel Murray O'Hara was assumed. Mr. Wynne emphatically stated that Owen Patrick O'Hara and Daniel Murray O'Hara were one and the same person. This fact was supported on the evidence of several tradesmen who had supplied goods to the same individual under both names. Mr. Wynne further stated that on the counterfoil of the

death certificate refused by the Registrar the original signature O. P. O'Hare had been altered to D. M. O'Hara. Mr. Wynne explained that he was not himself a registered medical practitioner. A clerk from Mr. Neede's office deposed that P. M. O'Hara called at Fleet Street on Wednesday last, and that he and O'Hare, whom witness knew well, were one and the same person. A solicitor from Liverpool, to whom O'Hara applied to assist him in obtaining the restoration of his name to the Medical Register, from which, during his absence abroad, it had been omitted, also attended. This application was made in November, 1882.

After some time spent in private deliberation, it was resolved that the name of D. M. O'Hara, which had been fraudulently restored to the Register at the instance of a person named O'Hare, be struck from the Register.

CONJOINT EXAMINATION.

Dr. HALDANE moved—"That the scheme of conjoint examination to be conducted by the Royal College of Physicians of Edinburgh, the Royal College of Surgeons of Edinburgh, and the Faculty of Physicians and Surgeons of Glasgow, be received and entered in the minutes."

Dr. FITMAN moved an amendment to the effect that any such conduct on the part of the Council would be unbecoming at a moment when it had under its possible consideration a scheme for conjoint examination in all divisions of the Kingdom. This not being seconded, it fell to the ground, and the motion was carried.

Dr. HALDANE next moved that the Council should approve of the suggested co-operation, and in defence of the proposal, pointed out that in England circumstances led to comparatively few University degrees being given in medicine, whereas in Scotland large numbers took University qualifications. The proposed scheme was devised when the failure of any other scheme was seen to be assured. It aimed to prevent the abuse of single qualifications to practise. Should the proposed enlarged conjoint scheme already hinted at in the Council be carried out, the Scotch scheme would cease to be attractive to English students. The examinations were proposed to be inspected by visitors, and would be conducted with the utmost care and circumspection. It might be objected that the time was inopportune for such a scheme, but there was no certainty of legislation this year being carried out.

Dr. STRUTHERS seconded the motion.

Mr. SIMON remarked that no like proposal to this had been made during the twenty-six years of the Council's existence. The time chosen for it was inopportune, since if the Medical Bill became law it would provide for combination of all the authorities in each division of the Kingdom. If the Council gave the approval asked for, it would be urged in Parliament as an argument against the Bill. He did not think the Council could possibly, after twenty-six years, accept a partial plan for combination which it had all along consistently urged. He thought it would be well to defer further consideration of the subject till next year, pending the fate of the Medical Bill.

Dr. AQUILLA SMITH thought a strong objection to the scheme was found in the power of withdrawal it provided at the end of five years, on the part of any contracting corporation named in it, on giving a year's notice.

Mr. MACNAMARA thought it unwise to consider the details of the scheme. It ought to be regarded broadly. Mr. Simon's objection might be applied to the other side of the question, and the duty imposed on the Council by Act of Parliament ought to be fully performed, whatever might be taking place in Parliament. Rejection of the scheme ought only to follow its consideration clause by clause. He was convinced the co-operating Colleges were influenced by absolute *bona-fides* in framing its proposals, and it would be unworthy to reject it on the ground that Government had introduced a Medical Bill. He sincerely hoped the Bill, with some modifications, might become law, but it would certainly encounter violent opposition, and its chances were very small.

The debate was adjourned on the motion of Rev. Dr. Haughton.

His Royal Highness the Prince of Wales has promised to open the International Health Exhibition on Thursday, the 8th of May, at 3 p.m.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, APRIL 2, 1884.

THE OUT-PATIENT DIFFICULTY.

THE Hospitals Association held its first ordinary meeting at the rooms of the Medical Society of London last Wednesday, when Mr. W. J. Nixon, House Governor of the London Hospital, read a paper on "Difficulties Associated with the Administration of the Out-Patient Department, and how best to deal with them." It must be a matter of deep satisfaction to the Council of the Association that they have been enabled to commence their active campaign with the aid of so veteran an official, and one so thoroughly identified with hospital management as the author of this communication has proved himself to be; and if we may be permitted to anticipate the nature of future results from that of the beginning already made, we may safely predict that a course of exceeding usefulness lies before the young Society which has been formed with the object of promoting efficiency and economy in all pertaining to hospitals administration. It would be impossible to name anyone who, more than Mr. Nixon, would have been fitted to deliver the first paper destined to excite discussion among the members of the Association; for no one probably among all the recognised authorities in connection with the subject, has either been so long actively engaged in actual administrative duties, or has shown such persistent and intelligent appreciation of, and successful dealing with, the multitudinous difficulties that confront the managers of a great medical charity. At the London Hospital there

has, from the first period of its existence, been ample opportunity for the exhibition of tact and ability in the comprehension and harmonious arrangement of innumerable details, each with its special influence in promoting or retarding the successful working of the institution; and of late years financial burdens have pressed on it in a way to render more than ever onerous and difficult the task of discharging the duties that fall to the lot of a House Governor to perform. As in an ordinary house, so in a hospital, the *res augusta domi* becomes a potent factor in determining the manner in which domestic details are ordered; and the straitened circumstances that demand economy in the ordering of a workman's home, cry as loudly for a thrifty and efficient conductor when they influence the fortunes of a magnificent charity such as that over the internal affairs of which Mr. Nixon exerts a controlling power. In the paper to which reference is made above there is abundant evidence of the conviction of this truth on the part of its writer; and recognising that a most important element in the problem of hospital relief, and how to limit the claims upon it, is associated with the out-patient system, he set himself to face the question bodily, and to suggest a means for meeting the embarrassment created by the proportion to which this difficulty is extending.

Mr. Nixon at once assumes that out-patients form a legitimate class of claimants for hospital succour, and he shows that at the London at least, as far back as 1742, treatment of such patients constituted part of the regular work of the medical staff. He then proceeds to criticise the suggested methods of limiting the numbers of out-patients; by means, viz., of money payment exacted from them, and by limiting the number of daily admissions in those cases where payment is not insisted on. Neither of these propositions finds favour with him, and on grounds which, while being strictly reasonable, are at the same time unanswerable when the only legitimate *raison d'être* of hospitals is taken into consideration. "Charge for advice is," Mr. Nixon affirms,

"Unfair towards the professional man, who gives his services practically free to that great institution, from his honorary connection with which he looks for his ultimate reward—that reward which for good, intelligent, and faithful service he is certain to attain. Charge for medicine places the hospital in unworthy competition with the local practitioners in its neighbourhood, and, however small it may be, it is a heavy tax upon the *very* poor, who, it is known, can hardly procure bottles wherein to take away the medicines they stand in need of—those medicines which perhaps not infrequently are the only agents able to keep them from applying for that which they desire to avoid—the aid of the parish authorities. At the same time also the charge is a premium upon the dishonesty of a higher class who, whilst hesitating to accept absolute charity, have no objection whatever to take some little trouble—in fact, will cheerfully go out of their way for the sharp and pleasant practice of getting that, for which elsewhere they must pay one shilling, at the small charge of threepence. Numbers, therefore, are not, I think, likely to diminish under this *régime*, but self-respect does, in cases both of doctors and patients, and the treatment, moreover, of the surging crowd is carried on with

the accompanying consciousness that incivility, and even abuse, are by no means uncommonly associated with the demand for so-called charitable aid claimed as a right. And all the time, let it be remembered, the worthiest applicants are going to the wall—those, I mean, who, not being paupers, are just upon the verge of pauperism; and this class, if I am right in my investigations, is a very large one among the out-patients of the general hospitals."

These words, it cannot be too often remembered, are the utterances of a gentleman who for forty years has lived in constant observation of the class about whom he speaks. Their wants, their aims, their resources have been a constant study to him; and the conclusion at which he finally arrives it is impossible to impugn or question, for none so well as himself is in a position to judge what is required, and why.

On the question of limitation Mr. Nixon objects that the system must choke off many who are compelled thus to apply elsewhere; and on moral grounds he disputes the advisability of avoiding burdens which must of necessity, and in consequence, be cast on other institutions, possibly less able to support themselves, to endure.

In the way of remedy for the existing evil, however, he has a proposal to make which can scarcely fail to commend itself generally to all who really desire some sort of reform in this connection. This consists in a plan of *inspection*, not, as Mr. Nixon carefully explains, of an indiscriminate kind, but applied with "careful, charitable, and discerning intelligence." It is to be both social and professional in its bearings, and the social inspector is to have no kind of association with the professional, to whom each case that presents will be in the nature of a query as to whether illness of a serious kind and demanding continuous treatment is shown by it. But in no case would summary and immediate refusal of attendance be accorded, for Mr. Nixon very properly remarks—

"Remembering that no untrained eye can discern those hidden maladies, laden with which men and women still walk about our streets, themselves conscious of no mortal ill, but solely of some indefinite pain of which they desire to be rid, I would recognise in all cases the right of appearing once before the hospital physician or surgeon. With him should thenceforth rest the decision as to need for further treatment and the power of conceding it. And more than this, the skilled hand and eye of the professional attendant should not only decide these points in reference to cases suited by circumstances for gratuitous aid; but in event of urgency being recognised in a case presumably socially unfit, or symptoms being diagnosed valuable in their tracing out, for the promotion of medical or surgical science, he (the medical attendant) should be at liberty to neutralise thenceforth all social inquiries whatever, as things subordinate to the higher interests of the patient at the moment—of the community in the future."

If we can accept such carefully weighed opinions as these as indicative of the spirit that is destined to animate the proceedings of the Hospitals Association throughout its existence, then of a surety we may implicitly intrust to it the working out of those great changes that are nominally its programme. Its deliberations will give a tone and colour to the agitation for

reform in administrative matters which have never yet been apparent in what has been said and done, by spasmodic as it were, and without definite aim or end in view. Mr. Nixon has worthily and ably inaugurated the work the Association has essayed to accomplish; and in the manner that his commencement is followed up by other labourers shall we have to look for the future evidence of accomplished good.

THE COMING MEETING OF THE BRITISH MEDICAL ASSOCIATION.

THE arrangements for the Belfast meeting of the Association have, we regret to hear, pleased no one, and as a consequence we are apprehensive that the meeting will be only a partial success. The selection by the local committee of those who are to occupy the posts of honour in the meeting has given, we understand, the direst offence, not only outside Belfast, but to a section of the local practitioners, who think themselves insufficiently recognised. The Medicine Section, for instance, is officered by a Belfast President, a Liverpool and a Dublin Vice-President, and a Belfast and a London Secretary. The Surgery Section, by a London President, two Belfast and one Edinburgh Vice-Presidents, and a Belfast and a Birmingham Secretary. The Obstetric Section is to have a London President, Vice-Presidents from Aberdeen and Derry, and Secretaries from Manchester and Belfast. The Public Medicine Section is to be presided over by a Glasgow President, Vice-Presidents from Bristol and Belfast, and Secretaries from London and Belfast. The Ophthalmological Department is to be governed by a Belfast President, by Vice-Presidents from London and Liverpool, and Secretaries from Leeds and Belfast. In the Physiological Department the chair will be taken by an Edinburgh President, the vice-chairs by gentlemen from Cork and Glasgow, and the secretarial business will be done by Secretaries from Belfast, Manchester, and Galway. In Therapeutics the Section will be administered by a London President, by Vice-Presidents from Aberdeen, Belfast, and Dublin, and Secretaries from Belfast and London. Lastly, Psychology will be presided over by a London President, two London and Dublin Vice-Presidents, and Belfast and Exeter Secretaries.

From this analysis of the list of officers it appears that the Belfast local committee has been able to find in Ireland but little merit outside their own town and themselves, and have found it necessary to resort to England and Scotland for men to keep their greatness in countenance. The working of the coming meeting has, in fact, been placed in the hands of officers from

Belfast and Vicinity	...	...	...	15
England	...	...	...	17
Scotland	...	...	...	6
All Ireland outside Belfast	...	...	...	5

Probably the local committee are better informed than the rest of the world as to the scientific prestige which entitles the northern capital of Ireland to put itself in the post of honour to the exclusion of its own guests. It does not, however, appear from the foregoing list that modesty is one of those qualities cultivated in the

modern Athens to which they belong. The studied omission of Dublin from a place in the scientific management of the coming meeting is, we are aware, regarded as a deliberate intimation from Belfast that the presence and co-operation of the profession in Dublin is not desired, and, already, we hear that the surgeons and physicians of the Irish metropolis who object to pipe for the dancing of the Belfast performers are arranging for their summer holiday anywhere but in the north of Ireland.

Amongst the other eccentricities of the coming meeting is the entire omission from the programme of an Address in Surgery, an arrangement which is almost without precedent in the history of the Association. To what consideration this omission may be due is difficult to conceive. Is it possible that, supposing Ireland to be excluded, there is no English or Scotch practitioner fit to address the Belfast surgeons? or is it rather that the local luminaries are unwilling to undertake a surgical oration which might extinguish the light of their visitors by its superior effulgence? Whichever be the explanation, the fact remains that the part of Hamlet is to be by special design omitted from the play.

Lastly, we hear that an anonymous party or person in Belfast itself has been making every effort to prevent the advent of strangers to the meeting, and to cover the proceedings with obloquy. This party has disgraced itself by issuing a series of anonymous letters addressed to a very distinguished London physician who had undertaken a prominent rôle for the occasion, warning him that his participation in the proceedings would not be welcome in Belfast, and that he had better stay at home. Furthermore, these anonymous scribblers have given expression to their envy, hatred, and malice by a doggerel entitled "Caleb in Search of a Knighthood," which they have circulated widely amongst the leading members of the Association, and which is devoted to sneering at the chief officers and readers of addresses, and to a vulgar and evidently malicious depreciation of them.

However unfortunate the policy of the local managers of the meeting may have been, we hope that better counsels may prevail so far as to remedy the errors committed, and to make the meeting a success, as we should wish it to be, if for no other reason than for the discomfiture of the scribblers who dare not show their faces or honestly make their objections, if they have any to make.

PASSED AND PLUCKED.

THE table just presented to the General Medical Council, as reported in another column, giving the percentage of successful and unsuccessful candidates at the various examining boards of the kingdom, is of the utmost importance at the present time. The table shows that there has been a greater number of failures at the examinations now than formerly, and it also shows where those failures occur. These results may be due to one of two causes—either a greater stringency in the examinations or to the state of panic into which the examining boards have been thrown by impending legislation. The explana-

tion probably lies in a combination of both causes at work. It will be noticed, also, that the number of failures is more pronounced at the primary examinations than at the final. It may be suggested that either the examinations are more searching, or that the preliminary teaching is deficient, or that the periods of the examination are so far apart as to engender idle habits in the students, or that the preliminary school training has failed to inculcate those habits of application which can alone ensure success. Here, again, the explanation is probably to be found in all the causes suggested, but chiefly in the early school training. Be these as they may, the table just quoted lays bare one of the weakest points in the Medical Bill now before Parliament. To enforce the truth of our statement we must refer to our article in a recent number on the Scotch Conjoint Scheme. We there pointed out that the Scotch medical institutions differed in many most material points from those of England. The Scotch Universities through their degrees virtually grant licences to practise, and grant them freely; the English Universities do not. The Scotch Universities are also teaching bodies; the Corporations are not. The Medical Bill leaves the examinations in the primary subjects—those in which the greatest percentage of failures occur—to the Universities and Corporations. Now, one of two things must follow—either the slow but certain extinction of the Scotch Corporations, no matter how many representatives they may have on the Divisional Board; or a lowering of the standard now existing in the primary subjects of medical education. The manner in which this will be brought about is as follows: The student going to Scotland will naturally attend the University, for by so doing he will have the option or not of taking the degree together with the final State examination, which he must pass. But there is another alternative—the primary examinations of the Corporations will be open to him, and unless care be taken, the primary education in chemistry, anatomy, and physiology must as a result suffer. The existence of the Corporations will depend upon the number of those they may be able to attract to their primary examinations; and it is well known that a showy examination in the final subjects may be passed at any College with the most paltry knowledge of anatomy and physiology, which, together with chemistry, forms the tripod on which the science of medicine does and must rest. To obviate this *contretemps*, and which we should exceedingly regret to see, the examiners in the primary subjects must be elected by the Divisional Board, and not by the Corporations, a proceeding to which they are not likely to submit. The course left open to the Corporations is either to meet their fate with a divine resignation or to become as the Universities are—teaching bodies, and by raising the standard of their examinations for the Fellowships, render these equal in public estimation to the University degrees. These remarks apply of course only to Scotland, where the examining bodies have always been in competition. It is entirely due to the dread of legislation that an examination for the Membership and Fellowship of the Corporations has been wrung from them, and those engaged only know how keen has been the struggle, and how reluctantly the concession has been made.

Notes on Current Topics.

The Place of Physics in the Curriculum.

A LENGTHY discussion originated at the General Medical Council on Thursday last in connection with the question of mechanics and physics as parts of the preliminary education of medical students, and in the course of it several interesting facts were revealed. It will probably surprise none who are at all familiar with the methods of the Council to learn that one of its regulations has for a long period been systematically neglected, and that it has now found itself under the necessity of declaring that it considers observance of its specific requirements as a matter of some importance. This relates to the examination of students in elementary mechanics, and which, according to the Registrar, is not observed by any but a small number of such as register. The discussion arose out of a letter received from the Secretary of St. Thomas's Hospital Medical School, in which, after quoting from the Council's "Regulations" that "the subject of elementary mechanics, &c., may be passed either as preliminary, or before, or at the first professional examination," the writer proceeds to state that confusion exists in the minds of students as to whether being registered by the Council on the strength of an examination which did not include mechanics, they would still be called upon to pass in this subject. It seemed to be a revelation to many members of the Council that its express demands are systematically ignored by large numbers of students; but, as was pointed out by Dr. Haughton, it is quite impossible, under existing arrangements, to secure that every candidate for qualification shall be examined in elementary mechanics; but, notwithstanding this, it was deemed wise to accept Mr Simon's resolution, insisting on a due observance of the regulation of the Council; Sir Henry Pitman observing that students must find out for themselves a way of complying with it. Mr. Simon seems, indeed, to have a most exaggerated respect for the science of mechanics, asserting that of all preliminary subjects it occupies the most important place; but accepting Dr. Haughton's interpretation of his description of its applicability to sanitary engineering, it would appear that Mr. Simon's idea of mechanics is not that universally entertained, since it includes also the sciences of heat and thermo-electricity. However this may be, the Council has decided to believe in itself once more, and to insist on the carrying out of its own regulations.

THE highest annual death-rates from diseases of the zymotic class in the large towns last week were—From measles, 7·1 in Portsmouth, 4·3 in Oldham, 4·0 in Norwich, and 3·8 in Nottingham; from whooping-cough, 2·4 in Bolton, and 1·3 in London; and from scarlet fever, 2·6 in Leeds, 2·0 in Manchester, and 1·6 in Preston. The 36 deaths from diphtheria included 13 in London, 5 in Glasgow, 3 in Leeds, 3 in Hull, 2 each in Edinburgh, Brighton, Portsmouth, and Birmingham. Small-pox caused 4 deaths in Birmingham, 3 in London, 3 in Liverpool, and 3 in Sunderland.

A Curious Difficulty.

DURING a great part of its sitting on Saturday, the General Medical Council was engaged in the consideration of what is probably the most complicated case of fraud with which it has ever been called upon to deal. It seems that last year application was made to the Branch Registrar for Ireland to restore the name of Daniel Murray O'Hara to the Medical Register, from which, during the asserted absence abroad of O'Hara, it had been omitted. Owing to irregularities, the exact nature of which is hardly yet cleared up, the application on being referred, for confirmation of leave given, to the General Council, was made a subject of discussion, with the result that further inquiries were directed to be instituted into the facts of the case. Consequent on these there has been exposed a fraud of the most daring description, perpetrated by the presumed O'Hara, who has now been shown to the satisfaction of the Council to be in reality a person named Owen Patrick O'Hare, and who had assumed the title of a deceased practitioner for purposes of registration. From the evidence given before the Council on Saturday, it is conclusively shown that this must be the case, several instances in which the identity of the person taking on the duplex individuality could be proved beyond dispute, having been recorded. The interest of the case, however, centres in the fact that a system of imposture of this nature could so far successfully be carried out as to obtain for its author so much of recognition as is implied in the acceptance of his credentials by a Branch Council. Unless, too, it had happened that a certificate signed inadvertently "Owen Patrick O'Hare" had not been rejected by a registrar of births and deaths, on the ground that no such person was registered as a medical practitioner, it seems as though no inquiry would ever have been instituted into the matter. The returned certificate, however, was replaced by one bearing the signature of "Daniel Murray O'Hara," and though this name was also absent from the Register, for some unexplained reason it satisfied the registrar, and was accepted. A long series of frauds against the pseudo O'Hara was adduced and proved; and having failed to answer the summons to appear before the Council in person, he was adjudged by default to have been guilty of the personation alleged against him; and, of course, the application for registration was refused. Complications innumerable arose in connection with the case, and it seemed almost hopeless to unravel its intricacies; but there can be no question of the justice of the final decision of the Council, which has, by it, as far as possible vindicated the outrage attempted on its dignity.

Rice v. The Prisons Board.

By the decision given last week by Mr. Justice Murphy at Galway, the Irish Medical Association has succeeded in establishing the principle that, where a prison surgeon is away from duty on Crown business his substitute must be paid by the prison authorities. The facts are these: Dr. Kinkead, the surgeon, had been called to give evidence before the Royal Commission on Irish Prisons, and, on leaving Galway, he made entry in

his gaol journal recommending Dr. Rice as fit to discharge his duty. The Deputy Governor, who was in charge of the prison, sent the recommendation to the Board in Dublin, who sent back their approval. Thereupon the Deputy Governor wrote to Dr. Rice, informing him that Dr. Kinkead "had recommended," that the Board approved, and that he was requested to attend and do the duty, and this request Dr. Rice complied with, having had no communication whatever with Dr. Kinkead on the subject. When he applied for his fees the Prison Board referred him to the Secretary of the Commission, who referred him to Dr. Kinkead, but he refused to allow his claim to be shifted to anyone, and placed his case in the hands of the Irish Medical Association for redress. Meanwhile the Prisons Board directed Dr. Kinkead to pay Dr. Rice, which, under protest, he did, but Dr. Rice returned the cheque, and proceeded with his action. When the case came before the County Court the facts do not appear to have been put properly before the Judge, for he dismissed Dr. Rice's claim, but on an appeal from that decision the superior court has reversed the dismissal and ordered the Prisons Board to pay all costs.

Dr. Rice's case was based on two contentions—first, that he was duly retained by the prison authorities to do the duty, and that they were under contract to pay him, no matter what their relation with Dr. Kinkead might be; secondly, that as a fact, Dr. Kinkead was not liable to pay. The rule governing this is as follows:—

"107. In case of sickness, or unavoidable absence, or leave, to be given by the General Prisons Board, the surgeon shall appoint a fully-qualified substitute, approved of by the General Prisons Board. The name and residence of the substitute shall be entered in his journal."

It was contended that Dr. Kinkead's absence was not "unavoidable," as it was the act of the Prisons Board itself, and that, in any case, neither the Act of Parliament nor this rule declares that the surgeon is to pay the substitute.

We are extremely glad that the hands of the Irish Medical Association have been strengthened by the judge's decision, and that a fitting rebuke has thus been given to the arrogance of the Prisons Board and the meanness of the Treasury. It is some satisfaction that individual practitioners have someone to fight their battles against this rampant bureaucracy.

Listowel Union.

THE Guardians of this Union have elected Dr. Cussen as the Medical Officer of their workhouse. It will be recollected that they had on three occasions elected Dr. Dillon, and that he had been each time unseated by the Local Government Board for Ireland because of his having admittedly purchased the resignation of the last incumbent. At length the Board informed the Guardians that if they did not elect some one else the Board would itself do so, and accordingly they chose Dr. Cussen. Meanwhile Dr. Dillon proceeded at law to set aside the order of the Local Government Board, but when the case had been partially heard it was discovered that he should have given a ten-days' notice of the proceedings. The case was postponed to enable this to be done, and it will probably be reopened at the April sitting of the Dublin Law Courts.

The late Dr. Allen Thomson.

At the commencement of the General Medical Council's proceedings on Thursday last, the President, Dr. H. W. Acland, referred to the fact that at 3 o'clock the remains of the late Dr. Allen Thomson would leave Euston Station on the way to be interred in Scotland. It was then resolved that a deputation from the Council should attend at the Station; and Prof. Marshall, Dr. Aquilla Smith, and Dr. Struthers were chosen to perform this duty. On returning subsequently, Mr. Marshall announced the fulfilment of the task allotted to the three members, and described the scene in which they had taken part as most impressive. A large number of representative scientific men were present at the Station, among whom were the President of the Royal Society and other eminent biologists, &c.

Preserved Meat.

DRS. UNGAR and Bodländer, of Bonn, have recently been engaged in making an inquiry as to whether the contents of preserved meat-tins contain any appreciable quantity of the metal of which the tins are composed, and the conclusion they have arrived at is that a not inconsiderable quantity of tin passes over into the conserve. They could not decide upon the precise form in which the tin was present, but they ascertained the fact that it was not in a soluble form, or, at any rate, in a combination not readily soluble. Experiments on dogs and rabbits showed that the tin was absorbed by the intestinal mucous membrane, and it was detected in the urine, heart, liver, kidneys, spleen, brain, and muscles. They explain the fact of so little being heard of tin-poisoning in human beings by the comparatively recent introduction of tinned meats as an article of food by their high price leading to a minimum consumption, and finally to the presence of other metals, especially lead, used in soldering, to which symptoms of poisoning, when such do occur, are generally attributed. It is important that our knowledge on this point should be accurate and beyond doubt, as tinned meats are much used amongst us, and if the danger is real, the best safety will lie in facing it.

The Medical Register.

THE Register has just made its appearance, and it bears evidence of the continued assiduity of Mr. Miller, as evinced by the elimination of errors which had multiplied in times past. The multitude of names of practitioners long since deceased which had accumulated in the list by reason of the steady addition of new entries, and the omission to remove the names of those who had ceased to be, is palpably reduced, and it may now be taken that the presence of a name in the Register is *prima facie* evidence that its owner is living at the address given. The total strength of the profession officially inscribed for 1884 is 24,517, that for the year 1883 being 23,801; the number for the last year being the highest yet reached. The increase seems to have been entirely due to the influx of new practitioners, for we find that in the year 1882, 1,171 new names were added—the average in the six preceding years being 1,020; while in the past year 1,304 new entries were made, and 710 names were

removed by reason of death, and on looking to this item in successive years it is manifest that a careful watch is being kept by the Registrar upon the available records of deaths. At the present date the Register contains 24,517 names, whose place of registration was as follows:—

				Percentage of the whole.
England	...	16,566	...	67.57
Scotland	...	4,045	...	16.50
Ireland	...	3,906	...	15.93

It must be recollected that these figures do not at all represent the nationality of the practitioners inscribed, because a very large proportion of the Irish and Scotch students do not register until they have entered into practice as assistants in England, and thus their money and their entries go to the London office, and not to the branch registries of the countries where their education has been obtained.

The registration and restoration fees yielded no less a sum than £6,707, while the accumulated funds of the Branch Councils produced an interest income of £1,016. The printing of the Register cost over £420, while its sale only realised £31; but this loss must be considered inevitable as long as the law stands which requires that 3,247 copies should be given away gratuitously to various legal functionaries and to all newly-registered practitioners who please to claim them.

Death of a Medical Man from Chloral.

WE regret to announce the death from an overdose of chloral at Stockton-on-Tees, of Dr. John Middleton. Deceased, a Graduate in Honours of the Edinburgh University, was a retired Surgeon-Major of the 2nd Life Guards, and spent about thirteen years in India, whence he returned to England in bad health three years ago, and in November last, he commenced practice in Stockton. He was subject to sleeplessness and took chloral, but only as a last resource, to induce sleep. He was very unwell on Tuesday, and kept his bed all day. At night he called the housemaid to his room, and said to her, "Oh, Eliza, I have taken too much chloral." He became unconscious and died soon afterwards. Dr. Beatty, of Stockton, made a post-mortem examination of the body, and found that although the heart, liver, and kidneys were affected with fatty degeneration, death was due to an overdose of chloral. Deceased had repeatedly expressed a wish that he might live to see his three motherless children grow up. At an inquest held on Thursday last the jury found that he died from the effects of an overdose of chloral taken by mistake.

Dr. Acland's Address.

The opening address of the President of the General Medical Council is chiefly remarkable for his declaration in favour of the Medical Bill, "the broad principles of which," he says, "will not, with the present tendencies of political action, be departed from." He considers that this Bill "is the only way now known of quieting the disturbed state of education in the medical schools, and of getting into a more reasonable and uniform shape the increased mass of knowledge which our students are required to produce at the examining board."

This pronouncement, emanating as it does from the chief

of the Medical Council—the most conservative medical institution in the kingdom—and from the medical head of the most conservative licensing body in existence, ought to convince the uninitiated who have recently rashly undertaken to give their opinion on the subject, that they had better accept the principle of the Medical Bill as unquestioned, and apply themselves to the amendment of details.

The President of the Medical Council finds the Bill imperfect in only one respect, i.e., that it touches with unholy hand the sacred person of the Medical Council. He expresses his opinion that “the persistent determination that no Bill should be permitted to pass unless the Council were altered in its constitution has produced the result of hampering educational progress, and causing waste of time, suspense, and uncertainty.” We venture to remind the learned President that “any waste of time, suspense, and uncertainty” which has existed has been of the making of the Medical Council, which has for years disregarded public opinion and the public welfare in the effort to preserve itself unreformed. Most properly and most wisely the profession has refused to accept a shadow of reform, while denied the substance; has rejected the offer of improvements the working out of which were to be entrusted to a discredited and effete self-glorification company. “No reform without reconstitution” has been the watchword which has brought the profession within reach of reform; but we are obliged to say that there is a present danger of medico-educational reform being swallowed up in the cry for direct representation. We warn our readers against the party who are working for a direct representation Bill, forgetful or ignorant of the still more important reforms which the Bill should contain.

Dublin Hospital Management.

At the last meeting of the Dublin Fortnightly Club, Mr. Lambert H. Ormsby, F.R.C.S., read a very interesting paper on “Hospital Management and Reform,” in which he dealt with the following subjects:—1. Governors and the management of hospitals. 2. The election and appointment of managing committees. 3. Hospital finance and audit. 4. How to encourage the public to support hospitals. Arguing that the existing arrangements respecting these matters were not satisfactory, he proposed—

a. That all ornamental governors who did not represent grants in aid of the hospitals should be removed from the managing committees in order to make room for those governors who had a natural aptitude for hospital matters.

b. That the same committee should not as a matter of right be re-elected year after year, the “house lists” being abandoned. That the election should be thrown open to all the governors or subscribers entitled to vote, the medical and surgical staff being also largely represented on the managing committee.

c. That Dublin hospitals should adopt some uniform method in keeping their accounts, and then a comparison of expenditure could be accurately made; no hospital to be allowed to audit its own accounts, the services of a public auditor being in all cases secured.

d. That any hospital receiving support from private charity should prove beyond any manner of doubt that efficiency and economy pervaded every department in the institution.

Also that each general hospital should map out for itself a district or area to which it could definitely appeal for support, so as to localise both the relief which it affords and the area from which it derives the greater part of its income.

The Duke of Albany's Death.

THE very fragmentary reports which have been received respecting the much-regretted death of Prince Leopold have left the cause of death very much a matter of speculation and dispute in medical circles. There does not seem to be any good reason for supposing that the injury to his knee which the Duke had sustained had any immediate connection with the unhappy sequence, but it may be that it had its effect as a determining cause of brain excitement, which resulted—in a patient of known hæmorrhagic tendency—in a sudden cerebral bleeding, and death from the apoplectic effusion. A remarkable instance of fatal bleeding of this character was communicated to the Academy of Medicine of Ireland by Dr. William Frazer, of Dublin, on the 16th of March, 1882, and is reprinted in the Academy Proceedings—of an unmarried woman, aged about 50, the subject of frequent bleedings from stomach, lung, and nose whenever she was in any way excited or thrown off her balance. She presented no sign whatever of organic disease, but, nevertheless, was seized without any warning with a pain in her head, upon which coma speedily followed, and she was dead in a few hours, from, as Dr. Frazer believed, a cerebral hæmorrhage. There seems to be a close analogy between this case and the Prince's, which is stated to have first shown itself in the stertorous breathing, which is a usual indication of apoplexy.

The Cork Students and their Grievances.

THE newspapers of the southern city have, for the last couple of weeks, been made the medium for ventilation of statements respecting the anatomical fees required by the College, which a certain number of students seem to regard as sufficient cause for appealing to public opinion against their teachers and superiors. The alleged grievance is stated by their spokesman in the following terms:—

The Charter of the Royal University provides that students for the degree of M.B. must attend two courses in practical anatomy. After attending, the students of the Dublin schools are allowed to prosecute their dissections for a very moderate fee. In the Queen's College, Cork, strange to say, third year's students who wish to dissect, are compelled to pay for a third course of lectures in anatomy, besides the dissection fee, although the certificate is useless. We hold, sir, that the College Council in sanctioning this injustice are overlooking the following College statute, which states that—

“No professor shall be entitled to claim the fees of any class of students, except so long as that class shall be required by the Council to attend his instruction, and it shall be the duty of the Council to revise and amend the regulations prescribing courses of study from time to time, whenever they deem it conducive to the interests of the students so to do, irrespective of considerations affecting the incomes of professors.”

We have looked into this matter, and find that the Queen's College students, so far from having any grievance to complain of, are treated with the greatest leniency in the matter of fees. In the first place, the total cost of anatomical teaching and subjects is about half what they would have to pay in any Dublin school. In the second, they are permitted, if they wish, to pay a composition fee which entitles them to dissect to the end of the chapter on paying merely the cost of preserving and

preparing the subject. They can get their three years' dissection for £3 a year and £1 a year for subjects, so that the total outlay is only £12 for the entire anatomical course; but not content to pay this miserable sum divided over three years, they seek to obtain their entire period of instruction for £8; nay, more, they claim a right to go on for ever as dissectors and recipients of the dissecting-room instruction, paying nothing to the Professor save the actual cost of preparing the subject, and they even go the length of demanding that, if they do not choose to avail themselves of an entire subject, the Professor shall return to them at the end of the session as many shillings as will represent the market value of the unused material, thus putting the transaction on the same ground as a negotiation for butcher's meat.

There is, certainly, no just ground for complaint, and we do not believe that the Cork students are deserving of any sympathy in this matter. In any other of the schools in Ireland, than those of the Queen's Colleges, they would be required to pay the prescribed fee for every course of instruction they might please to take, and a claim to be returned a part of the subject-money would be simply laughed at.

We may be allowed to entertain doubts that young gentlemen who employ the time which they ought to devote to their work in public meetings and newspaper agitations will be likely to do much credit either to themselves or the profession, and we trust the authorities of Cork College will realise the fact that, if they yield to this sort of turbulent dictation, the hope of maintaining future discipline may be abandoned.

SIR WILLIAM GULL, M.D., presided on Thursday last at the thirty-second anniversary dinner of the Hospital for Sick Children, supported by the medical staff and one or two members of the nobility. The income of the hospital for the past year was stated to be £11,107. A special appeal was made for funds to meet the extensive building and drainage alterations in process, and £1,700 was subscribed in the room.

THE deaths registered last week in the principal large towns of the United Kingdom corresponded to an annual rate of 22.1 per 1,000 of their aggregate population. The death-rates in the several towns were:—Plymouth 15; Hull 17; Edinburgh, Birkenhead 18; Bradford, Leicester, Bristol, Sunderland 19; London, Bolton, Salford, Brighton, Norwich 20; Sheffield, Cardiff, Huddersfield, Birmingham 21; Derby 22; Blackburn, Newcastle-on-Tyne, Nottingham 23; Wolverhampton 24; Glasgow, Halifax 25; Portsmouth 26; Dublin, Liverpool, Manchester 27; Leeds 28; Oldham 30; Preston 31.

Scotland.

[FROM OUR NORTHERN CORRESPONDENTS.]

TERCENTENARY HONOURS.—The following is a list of those members of the profession who are to receive the honorary degree of LL.D. at the coming tercentenary of the University of Edinburgh:—Fordyce Barker, M.D.; Sir William Bowman, Bart., M.D., D.C.L., F.R.S.; Sir Andrew Clark, Bart., M.D.; Professor Cremona, Rome; Professor Ernst Curtius, Berlin; Professor Donders, F.R.S.E., Utrecht; Professor J. Eric Erichsen, F.R.S.; Professor Dr. L. Goldschmidt, University, Berlin; Principal Greenwood, Owens College, Manchester; Professor David Bierens de

Haan, Leyden; Dr. E. Haeckel, Professor of Zoology, University, Jena; D. Rutherford Haldane, M.D., F.R.S.E.; Rev. Samuel Haughton, M.D., F.R.S.; Professor Hermite, Académie des Sciences, Paris; Professor H. von Helmholtz, F.R.S.E., Berlin; Sir Wm. Jenner, Bart., K.C.B., F.R.S.; Thomas Keith, M.D., F.R.C.S.; John Marshall, F.R.S.; Professor F. Martens, St. Petersburg; H. Maudsley, M.D.; Sir W. Muir, K.C.S.I.; Professor Ollier, Lyons, France; Sir James Paget, Bart.; Professor von Pettenkofer, Munich; Professor Dr. O. Schmiedeberg, Strasburg; Professor B. J. Stokvis, Amsterdam; Professor Virchow, M.D., Berlin; Professor Villari, Paequale, Florence, Italy; Patrick Heron Watson, M.D.; Dr. George Wm. Balfour; Dr. John S. Billings, Washington; Dr. John Syer Bristowe; John Wm. Dawson, LL.D., Montreal; Prof. W. H. Flower, F.R.S.; M. Louis Pasteur, Paris; Ed. Henry Sieveking, M.D.; Rudolph Virchow, M.D., Berlin; Professor Frankland, and Professor Saxtorph, Copenhagen.

A LITTLE COMMON-SENSE ADVICE.—The winter session of Anderson's College, Glasgow, closed on the 27th ult., when a meeting was held in the Anatomy class-room, under the presidency of Dr. Marshall Lang. Among the gentlemen present were "Professors" (we are particular in the use of this term, as the teachers of this excellent, but originally very radical, school will insist on their titles, and much remind us, in this respect, of the *democracy* of our Transatlantic cousins, of which Mark Twain remarked that in throwing a stone at a bird a boy missed the intended object but hit four generals and several "professors") Morton, Dunlop, A. M. Buchanan, Dittmar, Gemmell, Christie, and Drs. Wolfe and Pirie. In the course of an interesting address to the students Dr. Marshall Lang said:—"Some of them might recollect what Goethe put into the mouth of Mephistopheles when in conversation with the medical student—how he represented Mephistopheles as looking at him and saying, 'In person you are tolerably made, in assurance you are not wanting—(loud laughter)—you are likely to grow in self-confidence—(hear, hear)—and the world will probably assume you proficient.' (Laughter.) For the rest, he represented the sapient doctor as knowing a thousand R's and O's. (Laughter.) That was a Mephistophelean view of the medical profession. It was not the world which he desired to set before students. Whatever they might be, let him recommend them to avoid all the savour of the quack. Let them not have life pills and all kinds of nostrums for curing every manner of ill; let them not be charlatans; and let them not live in an air of solemn professional importance. They should not be always speaking about the profession, and let them not stand upon little punctilios or mere matters of professional etiquette. The less a professional man brought his profession to the front, the more he acted like a man inspired by the high character of his profession and a true gentleman, the better for himself, the better for society, and the more would he be esteemed as a doctor."

GLASGOW.—SUSPECTED CASE OF ACCIDENTAL POISONING.—On the 24th ult., a man 44 years of age was found dead in his house in the East-end of the City. From inquiries made by the police it appears that the deceased got out of bed, and swallowed by mistake out of a gill bottle a quantity of hydrochloric acid. A friend who happened to call saw that the deceased was ill, and went out and got an emetic, which was administered, and the sufferer afterwards appeared to be getting better. The day following, however, he was found dead in bed, no other person being in the house.

HEALTH OF EDINBURGH.—The mortality in Edinburgh for the week ending with Saturday, the 22nd ult., was 82, and the death-rate 17 per 1,000. There were 21 deaths under 1 year, and 15 above 60, of which 3 were above 80 years of age. Diseases of the chest accounted for 45 deaths, and zymotic causes for 10, of which 1 was due to fever, 2 to diphtheria, 1 to scarlatina, and 1 to measles, the intimations of these diseases for the week being 15, 6, 31, and 79.

MORTALITY IN GLASGOW.—The deaths in Glasgow for the week ending with Saturday, the 22nd ult., were at the rate of 26 per 1,000 per annum of the population, as compared with 23 in the previous week, and 36, 25, and 28 in the corresponding periods of 1883, 1882, and 1881.

CURIOUS DEATH OF A DOCTOR.—We regret to announce the death of Dr. M'Donald, of North Uist, Inverness, under the following peculiar circumstances:—About a month ago a woman died there under suspicious circumstances, and was shortly afterwards buried. The authorities having been led to suspect that the death of the woman was somewhat mysterious, arranged for a post-mortem examination, and proceeded to the graveyard to have the body exhumed. A crowd of people assembled and prevented them, for which three ringleaders, sons of the deceased woman, were apprehended and imprisoned. Thereafter the authorities succeeded in raising the coffin without molestation. While attempting to open the lid, the coffin burst with a loud noise, one of the boards striking Police Inspector Mackenzie, and knocking him down. Dr. M'Donald, medical officer in attendance, fainted, and remained in an unconscious state for some time, but such was the effect of the shock upon his system, that, although able to carry out the examination later on, he died last week. The doctor was about 30 years of age. We have been informed that "professional jealousy" and ill-feeling lie at the bottom of this case. In that event the occurrence is a scandalous one, as only the most urgent circumstances would justify the exhumation of the body. Three sons of the deceased woman are at present in custody for endeavouring to prevent what they very naturally regarded as a sacrilege of their parent's tomb. Legally they may have been wrong, but morally, it will be generally admitted, if the reports which have reached us be true, that their conduct was entirely natural and praiseworthy.

PROFESSOR HAMILTON, of Aberdeen, is a candidate for the Chair of Pathology at Cambridge. The love of Scotch professors for English appointments is unabated. The professor would not gain in a pecuniary point of view, but then the position is so much better than that in Aberdeen. Scotch Universities are good stepping-stones to English ones, and the air of the south is so free and balmy!

TERCENTENARY GOSSIP.

IN another column we publish a list of the gentlemen who are to receive the honorary degree of LL.D. at the coming tercentenary. Some palpable omissions will be doubtless noticed, and it will be remarked that, while the President of the College of Physicians of Edinburgh is to be honoured with the degree, the President of the College of Surgeons of Edinburgh is left out in the cold. In thus ignoring the College of Surgeons the University is acting as a very ungrateful child, for the College can boast that it gave to the University its first professors. In fact, before the University had a medical faculty, the College professors gave all the medical education that Edinburgh had to give.

IN Edinburgh, where success depends so much on the sect

one belongs to, and on the ease in which the bodies of the vertebræ can be made to glide ball-and-socket fashion on one another, it is interesting to see a man passed over; not that he loved the University less, but that he loved his College more, and is anxious to defend its liberties from encroachment.

It is a pity that the tercentenary was not held during the session. Our German and French guests would have then had an opportunity of seeing our professors pretending to teach a class of six hundred students science. They would have been enabled to solve the mystery why home-grown science is nothing till touched by the hand of some German professor in some out-of-the-way German university. Why do students who want the doctorate in science of the London University go to Würzburg for botany and Munich for chemistry? Why does everyone who wishes to push himself in his own country boast that he *has* studied abroad?

YET, with all that can be said against some of the faults of the University, it cannot be denied that its success has greatly tended to magnify its faults and give them an undue prominence. This success is all the more gratifying in the fact that it has never fluctuated, but has been continuous and upward; and if the University ever falls off in its numbers, the cause must be sought, not in a deterioration in its teaching powers, but that its full growth has been attained.

AMID all this tercentenary rejoicing, nothing is heard of the Extra-Mural School—that School in which the medical greatness of the University had its birth, and from which the University still draws much of its inspiration and vigour. Where is the Extra Medical School? Disbanded and scattered about the town by an interminable struggle, in which private animosities take the place of strong union under broad principles.

"WHERE is the Extra-Mural School which I see stated on an advertisement bill?" asks a distinguished guest. "Where is your School?" "We have none." "Then you are a *vox et præterea nihil*?" "Just so!"

SURELY the Extra-Mural School might use this tercentenary celebration to unite, and the different members determine to pull more together.

THE University is apparently not rich in poets. The University offered the munificent gift of £10 for the best tercentenary poem or song for the occasion. Sixty candidates for the poetic laurel rushed into the field. Only three compositions were considered of any merit, and these were not deemed worthy of any further honour than the transitory amusement of the Senatus, who listened to them with, we are informed, much enjoyment. A volume of the rejected poems is, we learn, to be published, and then we shall have the opportunity of judging for ourselves as to their respective merits.

BUT because the undergraduates have failed to strike the quivering lyre, are we to have no song, no poem? Where is the author of "The Battle of Glen Tilt," or "Plain Cold Water?" Where is the topical poet of the College of Surgeons's annual dinner? Where is his jovial competitor on the same occasion? Where is the author of the "Tri Murti?" Surely we *are* to have a song? No song, no supper.

It has just been intimated that Lord Rayleigh is to represent the Royal Society of London on the occasion, and

the Earl of Stair, the Earl of Rosebery, the Earl of Galloway, and Sir Peter Coates have likewise announced their intention of being present.

Correspondence.

DR. CLIFFORD ALLBUTT AND GYNÆCOLOGY.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—It would be amusing, if it were not lamentable, to find one in such a position as Dr. Clifford Allbutt gravely, in his lectures before such an audience as the Royal College of Physicians affords, accusing gynæcologists of one-sided, or no-sided, pathology, and of working on blindly in ignorance of the fact that, many so-called uterine symptoms are neurotic. None are more alive than we are to the necessity of general treatment of sexual (I use the word as embracing all affections of the uterine organs) maladies. But when Dr. Allbutt taunts gynæcologists with being ignorant, or what is worse dishonest, in the practice of their own speciality, he only accentuates his own remark that, "no man limited by the bounds of human intelligence can have a fine knowledge of medicine, surgery and obstetrics," and though he says that "the speculum and uterine sound were invented as much for my benefit as for other people," yet he seems to stand in need, if he wishes to propound gynæcological dicta *ex cathedra*, of some course of clinical instruction in that speciality he sneers at. So far from "snubbing" our professional brethren, we, that are gynæcological physicians and teachers, are ever most ready to do all in our power to bring about a more wholesome and scientific appreciation of the various maladies that are constantly before our eyes. We are daily in a position to deplore the grave neglect of this most important branch of medicine and the healing art; receiving certificates of cases to be admitted into our hospitals either vague, as "uterine disease," or flagrantly in error. If the teachers of our speciality in the large hospitals would only take a little more pains to instruct their pupils, and, for this purpose, have greater facilities afforded them in their clinique, we should see in time a body of practitioners turned out who would make fewer mistakes in diagnosis, and who, by recognising uterine disease in its earlier stages, would do much to lessen the misery that is so rife; would retain patients that now drift into our hands, or by knowing when to call in a gynæcologist in consultation, would still retain their patient's confidence as well as their cases.

I am, Sir, yours, &c.,

GYNÆCOLOGIST.

London, March 27th.

Novelties.

SOLIDIFIED LINIMENTS.

We have received from Messrs. Savory and Moore one of the most ingenious and useful improvements in pharmacy to which our attention has been called for some time, consisting in what the inventors term solidified liniments. Struck by the annoyance caused by the use of liniments in their usual form, Messrs. Savory and Moore have devised this improvement on them, and by combining the active principle with a solid cerate base, they are enabled to produce an easily liquefied mass, which can be readily spread as required over the affected surface of the body, the natural warmth of which suffices to melt them. The liniments are put up in metal boxes, out of which they can be protruded by pressing on a movable bottom, and from trials of them we can speak most confidently as well of the comfort and cleanliness associated with their use as of the efficient action they exert in a therapeutic sense. Preparations in this solidified form have been made of cantharides, mustard, croton, aconite, belladonna, camphor, chloral, &c.

MALTO-PEPSINE.

THE undoubted advantages of malted preparations as articles of food have been so universally demonstrated that each candidate for professional favour, if carefully compounded, is wel-

comed as a useful addition to the physician's resources. In this connection a Canadian chemist, Mr. Hazen Morse, has produced a compound of pepsin and dry extract of malt, which combines the needed qualities of efficiency as a digestive agent and nutritive value as a food; and which, taken in doses of ten grains before meals, acts as a most beneficial and certain promoter of rapid digestion, and so ensures complete assimilation. In those forms of diarrhoea due to undigested food in the intestinal canal, from which young children are especially prone to suffer, this preparation acts almost as a specific; and regarded as a useful therapeutical aid to health, we can confidently recommend it for general use.

AN IMPROVED INHALING APPARATUS.

A NEW, economical, and effective form of vapour inhaler has been designed by Dr. George Stoker, of London.

The invention consists of a flexible cover (A), fitted with glass mouthpiece (B) and air tube (C), to carry the air through the medicated fluid. The ease with which it can be attached to various household vessels, such as a cup, jug, or jar, obviates the necessity of purchasing the reservoir used with most inhalers. Its portability and cheapness (being sold at the small price of 2s.), are, however, its principal recommendations, and by these it will doubtless achieve a very extensive popularity. The manufacturer's address is 36 Exeter Street, Strand, London, and the instrument can be had of chemists and druggists generally.

Medico-Parliamentary.

HOUSE OF LORDS.—MONDAY, MARCH 31.

MEDICAL ACT AMENDMENT BILL.

ON the order for considering the report of amendments in this Bill,

LORD CARLINGFORD said he was anxious that the Bill should reach the other House of Parliament before the Easter holidays, and he proposed that its third reading should be taken on Thursday. He had an amendment which he would move on Thursday relating to the constitution of the Medical Board in Ireland. Having added a representative to the Board from the medical colleges and corporations in Ireland, he had proposed at the same time to give an additional member to be elected conjointly by the Irish Universities; and he had had, as he thought, reason to think that that proposal would be acceptable. Since the last stage of the Bill he understood, on the contrary, that the proposal was extremely unacceptable, and he found it necessary to give it up. He would put an amendment on the paper that evening which would have the effect of giving an additional representative on the Board to each of those Universities.

THE DUKE OF RICHMOND could not conceive how there should be any such haste in proceeding with the Bill, because, even if it went down to the other House before Easter, was there any chance of that House proceeding with the measure for a very long time to come? During the last stage of the Bill now before their lordships, the noble lord had come to an understanding with Lord Cairns, and agreed to introduce a clause in reference to the representa-

tion of the Universities and medical corporations on the Board, and added that if the noble lord proposed to insert on the third reading a clause that would have the effect of giving four members to each University, and three to each Corporation, that was an alteration to which he should not object.

LORD CARLINGFORD said that was precisely the effect of his amendment, which would give four members on the Board to each of the Universities and three to each of the Corporations.

The report of amendments was then agreed to.

Pass Lists.

King and Queen's College of Physicians.—At the March examinations the following candidates obtained the licences in Medicine and Midwifery of the College:—

Medicine.

Beatty, Henry Bullen.	Kelly, Christopher Peter.
Craig, John.	Morice, Margaret.
Cuppaldie, Godfrey Oldfield.	Todd, Henry Ross.
Hickson, Robert.	Williams, George Robert.
Johnston, Benjamin Rigby.	Wills, Samuel Richard.

Midwifery.

Beatty, Henry Bullen.	Morice, Margaret.
Cuppaldie, Godfrey Oldfield.	Neary, Patrick.
Henry, Robert.	Williams, George Robert.
Hickson, Robert.	Wills, Samuel Richard.
Johnston, Benjamin Rigby.	

The undermentioned have been admitted Members:—

Christal, John.	Grant, Charles Scovell.
-----------------	-------------------------

Royal College of Surgeons in Ireland.—At meetings of the Court of Examiners, held on March 18th and 19th, the undermentioned was admitted a Fellow of the College:—

Cochrane, Robert Strangman.

Medical News.

A Cartwright Prize Medal.—We learn that the Association of Surgeons practising Dental Surgery has just instituted a Cartwright Medal or Prize for the best essay on Dental Surgery, and to be awarded either biennially or triennially, in honour of its President, Mr. Cartwright. The competition is open to all registrable medical practitioners, and Messrs. Imlach, S. H. Cartwright, and J. H. Craigie have been duly appointed trustees of the fund. We feel sure there are many who may feel disposed to subscribe, knowing the high esteem in which Mr. Samuel Cartwright, F.R.C.S., is held by the profession at large. Subscriptions or donations will be received and duly acknowledged by Mr. Hamilton Craigie, 13 Savile Row, London, W.

A New Association for the Study of Inebriety.—On the 25th ult., at a meeting of medical men held in London, a new association, entitled "The Society for the Study and Cure of Inebriety," was formed to investigate, from a scientific standpoint, the various causes of inebriety, and to educate the professional and public mind to a knowledge of these causes, and a recognition of the physical aspect of habitual intemperance. The officers for the first year are:—*President*—Dr. Norman Kerr. *Vice-Presidents*—Sir Geo. Burrows, Bart.; Sir Spencer Wells, Bart.; Sir Wm. Miller, Londonderry; Sir George H. Porter, Dublin; Sir Edwin Saunders; Dr. W. B. Carpenter, F.R.S.; Dr. Cameron, M.P.; Dr. Farquharson, M.P.; Professor MacLagan, Edinburgh; Dr. J. S. Bristowe, F.R.S.; Professor Macalister, F.R.S., Cambridge; Prof. McKendrick, Glasgow; Dr. C. J. Hare; and Dr. B. W. Richardson, F.R.S. *Treasurer*—Dr. C. R. Drysdale. *Secretary*—Dr. J. M. Caw. *Council*—Dr. Alfred Carpenter, J.P.; Dr. Jos. Eastwood, J.P.; Dr. Balding, Royston, Surgeon-General Francis, Surgeon-Major Evatt, Surgeon-Major Poole, Dr. Hart Vinen, Dr. Danford Thomas, Dr. Haynes, Malvern, Dr. Wickham Barnes, Dr. Sibley Hicks, Liverpool, J. B. Hevory, M.B., Dr. Geo. Robertson, Joseph Smith, M.R.C.S., Rickmansworth, Dr. Bridgewater, Harrow, Harrison Branthwaite, F.R.C.S., Willenden, Dr. Murray Lindsay, Derby, Dr. Alex. Peddie, Edinburgh.

DR. ALEXANDER P. DRUMMOND, lately assistant to Dr. Badger, Penicuik, has been appointed Medical Officer for the parish of Prestons, in succession to Dr. Jas. F. Cunningham, who is going abroad.

Notices to Correspondents.

THE BOYCOTTING OF MEDICAL ASSISTANTS.

To the Editor of the MEDICAL PRESS AND CIRCULAR.

SIR,—The wide circulation of your journal will no doubt ensure a pretty general perusal, by members of the medical profession in England, of Dr. J. Barter Langley's letter in your last issue. If his opinion be correct, and if, as he assumes, there exists at present in England a dislike to employ Irish qualified assistants, it is hardly probable his statement will meet with anything but silent assent. As this state of feeling, if it exist, may, therefore, escape comment, I, as an Irish qualified medical assistant and one of the many hundreds likely to be seriously affected by it, beg to draw the attention of the profession to the question, in order that such of the profession in England as do not share in what Dr. Langley supposes to be a general sentiment there, may repudiate the very narrow and bigoted views with which he, on what I consider very slender testimony, so generally accredits them. In the meantime, prompted by the idea that the enlightening influences of a medical education cannot have been altogether thrown away on the majority of English general practitioners, and having personally had agreeable experience to the contrary in more than one instance, I desire to say why I do not think Dr. Langley warranted, on the evidence he has adduced, in casting such a sweeping assertion on the English members of an essentially liberal profession. In the first place, Dr. Langley gives only one instance of bigotry, to support his gigantic hypothesis, and in the second, discloses the fact that the expression he quotes did not emanate from a medical practitioner at all, but from the said practitioner's wife, who, for all we know, may be a hysterical invalid or a person of unsound mind. So much for the evidence Dr. Langley offers with regard to the existence of a prejudice he laments; and now for the remedy he suggests, which is such a peculiar one that I am almost inclined to doubt Dr. Langley's seriousness in advancing it. Forsooth, he can only recommend "patience;" in fact he thinks the only way out of the matter is for the horse to wait till the grass grows. I think Irish assistants would be *asses* if they did. I will allow the expression of Dr. Langley's sympathy for Irishmen to pass unchallenged, and will also give him credit for the utility of keeping so many of them as his clients, but I certainly question the fact of his being singular in the latitude or justice of his views. There are ruffians belonging to every nation, not even excepting the English, but ruffians do not often obtain admission to the ranks of an honourable profession; Dr. Lamson and Palmer were hanged for murder, but that is no reason why the world should regard English doctors as a body of assassins.

Yours, &c.,

Rathmines, March 26.

AN IRISH ASSISTANT.

DR. SPENCER (Dublin).—Thanks. Your paper on "The Comparative Mortality from Phthisis in London and Dublin" shall appear as soon as space permits.

MR. E. WHITE WALLIS (London).—The report came to hand as we were at press—too late for present number.

MR. O. EGERTON JENNINGS (Newcastle).—See reply to Mr. Wallis.

WORKHOUSE INQUESTS.

ALIQUIS puts the following case: A tramp is admitted for the night into the "probation" ward by the Master of a workhouse, and dies suddenly during the night. An inquest is held, and the medical officer—who never saw the man alive—is examined by the coroner. Can the medical man obtain his fee? If not, would the same ruling hold good for the same reason if the clerk or guardian had dropped dead in the boardroom instead of the tramp in the ward? Is this the *spirit* of the law?

[The law bearing on this question is the 32nd section of the 9th and 10th Vic., cap. 87, which is as follows: "When any inquest shall be holden on the body of any person who has died in any public hospital or infirmary, or in any building or place belonging thereto, or used for the reception of patients thereof, or who has died in any county or other lunatic asylum, or in any public infirmary or other public medical institution, whether the same be supported by endowments or by voluntary subscriptions, then and in such case nothing herein contained shall be construed to entitle the medical officer whose duty it may have been to attend the deceased person as a medical officer of such institution as aforesaid to the fees of remuneration herein provided." We are of opinion that the "probation" ward of a workhouse comes within the clause, and that "Aliquis" cannot claim a fee. If the coroner had summoned a medical witness not attached to the workhouse the fee should be paid. Evidence as to death of a clerk or guardian would not come within the same category, as it would not be the medical officer's duty to attend them.—ED.]

DR. RUSSELL (Lincoln) will please receive our best thanks.

DR. S. D. T. (London).—Your suggestion has been anticipated. Dr. Routh's case, at the Medical Society of London, of "Sporadic Crétinism," was an exceedingly interesting one, and we hope to publish it in full so soon as the present pressure on our space is lessened and the engraving received from the engraver.

OPHTHALMOLOGIST.—The work of De Wecker and Landolt, referred to in Dr. Jacob's lectures, is not yet complete; the last volume (Vol. III.) is announced, but not ready; the subjects being Refraction and Accommodation.

VALEDICTORY ADVERTISING.

To the Editor of the MEDICAL PRESS AND CIRCULAR.

SIR,—Whatever may be your opinion on the nature of the private letter addressed by me to my patients on transferring my private practice to another medical gentleman (who, by-the-by, was not aware of the contents of that letter, but who certainly deserves the highest recommendation I could offer him), neither you nor the person whose

you a copy of it can, in justice, taunt me, as you seek to do, with having circulated it amongst other people's patients. Such an accusation, so plainly implied in your remarks, founded no doubt on information received, is unmerited and unjust. My letter (lithographed for convenience) was circulated exclusively amongst my own patients, and I took the precaution of marking it "private," so that it might not be given to non-patients to read. In writing out a list from my ledgers I carefully excluded those who might not be considered *bona-fide* patients of mine, and I forwarded my letter to the remainder only. I have that list by me at present, amounting to over 540 persons, most of them heads of families, and it represents to the fullest extent those, and those only, whose family physician or individual physician I believed myself to have been up to the time of my departure. It is, of course, just possible—though of this I have no evidence—that, unknown to me, two or three patients (certainly not more) may have gone over to the medical man who now launches in a covert manner, this formidable indictment against me, for I learned accidentally that this occurred to a very limited extent in the case of another, to whom I immediately wrote an explanatory letter, offering to correct the mistake, and receive, in return, a most gentlemanly and courteous reply. The complaining party has had ample time to collect his formidable list of examples. Let him, therefore, straightforwardly produce it, and I promise to afford him every satisfaction. Did I wish to enroach on him, or other medical men, would I have despatched my letter to one or two isolated patients of theirs, and have left the many unsolicited? I freely admit that many of the recipients of my letter were once patients of *certain* other medical men, but, of their own free will, came over to me, and continued to the last under my professional guidance. But, all these things considered, I cannot other characterize the implied accusation, in the broad sense in which it has been made, than as unwarrantable and unjustifiable; nor can I regard the attempt to use you, Mr. Editor, as instrument to blacken my professional reputation, as otherwise than the act of somebody too ready to grasp at any means, fair or foul, to injure a supposed opponent.

Admitting your right as a medical journalist to pronounce on matters relating to professional ethics, it is quite another thing, and a serious thing too, when broad insinuations, incapable of proof, and calculated to damage one's good name, are circulated in your journal throughout the medical world. The mere finding a letter of mine in the house of one who had ceased to be my patient is no proof that I was aware of the fact; it is certainly not proof of my having circulated it broadcast amongst other people's patients, or amongst a fractional portion of them. To accuse me of this circulating it (for your remarks in plain English are tantamount to this) is unjust and untenable. I defy the person who sent you my letter to sustain the implied accusation.

Regarding the recommendatory nature of my letter, it appears to me that if, in transferring one's practice, it be legitimate to speak flatteringly of one's substitute in private to one's patients, it should be equally legitimate to write flatteringly a private letter in his regard to one's patients. To hope to transfer a practice by a mere notification of the fact is a delusion. Patients must know whether they can place confidence in the man recommended; and should a verbal representation of his competency be impossible, a written one is called for, else the transfer is a mere sham. The extent of the recommendation would appear the only question. I believe (but in this matter I should, if otherwise convinced, stoop to your better judgment) that whatever can be conscientiously stated or written of him in this manner, may be without impropriety, provided that no comparison be instituted between him and others. However, I shall waive the consideration of this point, merely remarking that should any such letter be despatched indiscriminately, the transaction assumes another aspect; it then, and then only, ceases to be of a private nature, is tantamount to advertising, and should be regarded as highly unprofessional. That I have not stooped by word or act, directly or indirectly, to this latter I can attest before any tribunal. To accuse me of it, by implication or otherwise, is to do me a wrong which demands ample reparation. My professional character is dear to me beyond measure. It has never yet been tarnished; and, though leaving for a strange land, I would still jealously (indeed, all the more jealously) guard that reputation against unmerited reproach.

Woodside, Vernon Avenue, Clontarf,
March 27, 1884.

CHARLES MACCARTHY.

[We object to valedictory eulogies on principle, and we by no means agree that a physician who recommends to his patients, in private conversation, his successor in practice is equally at liberty to advertise the gentleman by 540 lithographed circulars. Patients should be left to judge for themselves as to the merits of their adviser, and, if they are aware that a recommendation by the outgoing practitioner is part of the consideration for which money is paid by the person recommended, they will probably pay little heed to the eulogium. We are certain that Dr. MacCarthy limited the issue of his circulars to those whom he regarded as his own patients, but equally certain that many of these 540 documents had reached persons who had passed into the hands of other practitioners without his knowledge. Unpleasantness of this sort is best avoided by refraining from circularising altogether.—Ed.]

THE GRIEVANCES OF THE BIRMINGHAM STUDENTS.

To the Editor of the MEDICAL PRESS and CIRCULAR.

SIR,—The dissatisfaction now rife amongst us is due not only to the appointment mentioned in your issue of the 29th, but it is intensified and aggravated by the circumstances of a simultaneous election to the Obstetric House-Surgery at the same hospital. For this post there were four candidates, viz., a M.R.C.S., L.R.C.P. Lond., a M.R.C.S., L.S.A. (*bona fide* alumnus) of the Birmingham School, a M.B., C.M. Edin., who had received a great part of his training here, and an *unqualified* student. This latter, a Cantab. alumnus (*sine* its degree), through the influence of powerful friends, obtained a pledge of support (in any event) from a number of electors, if he could manage to procure a qualification of any kind in the interval; this he did, obtaining the L.S.A. two days before the date of application, and he was elected over the heads of the other three candidates, though his seniors in

curriculum and knowledge. And this result would appear to be still more disappointing and extraordinary when you know that the selective power lies with the medical committee. Yet with us rumour has it that a committee so constituted is more "workable" and more open to malign influences than one composed of lay-members.

We students cannot but feel pleased to find that our long-pent-up grievances have at last been made public and found expression in your columns. I, personally, am sorry to be able to bear witness to such a statement but we have many, far too many, abuses in our midst, but none, I think, has excited so much discussion and angry comment amongst ourselves as the disgusting lack of interest in us and our welfare displayed by the great majority of our teachers and lecturers; the very men who are paid, and that handsomely, to give us means and opportunities for professional education.

But what do we see? Why, our efforts to raise the tone of the school and to do credit to the College and ourselves rendered abortive, owing to the marked disfavour with which those of our men who show anything amounting to average merit and intelligence are treated. Especially is this shown in the management of our hospital practice, where the case under notice is *only one* and a recent instance of the manner in which the posts which were constituted for, and intended to be filled by the most deserving students of our own school, are given up to other candidates, refugees from various centres of medical education, who chance to have friends on the elective committee or have taken the precaution of gaining votes by mercenary leverage or family influence.

Yours, &c.,

A (*BONA FIDE*) BIRMINGHAM STUDENT.

Queen's College.

DR. H. R. S.—The subject was referred to by Dr. Drummond Mac Donald in his paper on "Position in Labour," published in the *Medical Press*, August 22nd, 1883.

DR. J. L. (Liverpool), MR. SOAMES (Bradford), S. E. R. (Maldstone), A TEMPERANCE ADVOCATE (Dublin), and MR. WILSON (Glasgow).—See reply to Mr. Harrington.

Meetings of the Societies.

WEDNESDAY, APRIL 2ND.

ROYAL COLLEGE OF PHYSICIANS OF LONDON.—At 5 p.m., Luncheon Lecture: Dr. James Andrew, Etiology of Phthisis.

OBSTETRICAL SOCIETY OF LONDON.—At 8 p.m., Specimens will be shown by Dr. Godson and others.—Mr. Alban Doran, On the Relation of Prolapse of the Vagina to Hernia, illustrated by two Pedigrees.—Dr. Kilner, Upon the benefits derived from the Induced Current during Parturition.—Dr. Arthur Mitchell, On Strong Mental Emotion affecting Pregnant Women as a cause of Idiocy in the Offspring.

THURSDAY, APRIL 3RD.

ROYAL INSTITUTION.—At 8 p.m., Professor Tyndall, On the Older Electricity.

HARVIAN SOCIETY.—At 8.30 p.m., Mr. H. Cripps Lawrence will open a Discussion on Scarlet Fever—(1) Etiology, (2) Surgical, (3) Puerperal, (4) Differential Diagnosis.

FRIDAY, APRIL 4TH.

ROYAL COLLEGE OF PHYSICIANS OF LONDON.—At 5 p.m., Luncheon Lecture: Dr. James Andrew, Etiology of Phthisis.

ROYAL INSTITUTION.—At 8 p.m., Professor T. G. Bonney, The Building of the Alps.

ACADEMY OF MEDICINE IN IRELAND (Surgical Section).—At 8 p.m., Living Specimens by Dr. Hayes, Mr. Croly, and Mr. Lambert H. Ormsby.—Specimens exhibited by Card by the President, Dr. Hayes, Mr. Lambert H. Ormsby, and Dr. Jacob.—Papers: The President, Pharyngotomy.—Dr. McArdle, Notes on Stricture of the Rectum.—Dr. Lentaigne, Treatment of Compound Fracture.

MONDAY, APRIL 7TH.

ODONTOLOGICAL SOCIETY OF GREAT BRITAIN.—At 8 p.m., Casual Communications by Messrs. Storor Bennett, J. H. Munro, F. N. Pedley, and E. Lloyd Williams.—Mr. A. S. Underwood, On the Influence of Micro-organisms in the Production of Caries.

Births.

ATTHILL.—March 26, at The Laurels, Great Bentley, Essex, the wife of E. C. Atthill, L.E.C.P. Ed., of a son.

AYLING.—March 26, at The Oaklands, Upper Clapton, the wife of Charles T. Aveling, M.S., M.D. Lond., of a daughter.

CORLEY.—March 20, at 80 Lower Baggot Street, Dublin, the wife of Anthony H. Corley, M.D., F.R.C.S.I., of a daughter.

KIDD.—March 27, at 13 Montpelier Row, Blackheath, the wife of Walter A. Kidd, M.D. Lond., of a son.

Deaths.

BROWN.—March 21, at Brixton Road, after two days' illness, Robert Gibson Brown, M.R.C.S., L.S.A. Lond., aged 52.

COR.—March 26, at his residence, 74 Guildhall Street, Bury St. Edmunds, Thomas Coe, F.R.C.S., aged 68.

HARDING.—March 19, at 54 Lancaster Road, John Harding, M.B. Dub., late of Westbourne Park, aged 75.

HICKMAN.—February 19, suddenly, at Jhansi, India (Rifle Brigade), the result of an accident at polo, Arthur Hickman, M.D., L.E.C.S., L.E.C.P., A.M.D., of Dublin, aged 30.

HITCHMAN.—March 24, at Fairford, Mary Ann Hitchman, the beloved wife of Dr. Hitchman, F.R.C.P.L., late Superintendent Physician of the Derby County Asylum, aged 66.

NICHOLSON.—March 21, at Grove Road, St. John's Wood, John Nicholson, M.D., formerly of Lincoln, aged 69.

SCHULHOFF.—March 27, suddenly, at 46 Brook Street, London, W., Maurice Schulhof, M.D., of Vienna, aged 68.

RECENT ADVANCES IN PELVIC SURGERY. (a)

By LAWSON TAIT, F.R.C.S.,

Surgeon to the Birmingham and Midland Hospital for Women; Consulting Surgeon to the West Bromwich Hospital, &c.

IN obedience to the invitation of your secretary, I have very great pleasure in addressing this distinguished society as a slight recognition of the honour conferred upon me by admission to its membership.

I do not know that the physician by whose name this Society has marked itself, did anything which either directly or indirectly contributed to the advance of pelvic surgery, as we may surely conclude that pelvic surgery, save within the narrow limits of lithotomy and operations for piles, is a growth entirely of this century. It is true, at least, I believe I have established the fact, that the first ovarian tumour operated upon was removed in Renfrewshire, by Dr. Houston in 1701, but such an operation as that known as ovariectomy may really be considered as abdominal rather than pelvic, and even that dates its establishment within our own century.

From the fact that my own practice is confined to the diseases peculiar to women, so completely that I do not suppose I see on an average one male patient a year, and then he comes for abdominal and not pelvic surgery, I am wholly unable to speak of the recent advances in the treatment of the pelvic diseases of men. What I have to say is of work in a wider and more varied field, the pelvic diseases of women, and this field practically remained closed till the year 1878. The light of progress did not shine till we awoke to the fact that, Keith by giving up the clamp had brought his ovariectomy mortality down from 20 per cent. to 5, so

that all done since then is, in a large measure, to be credited to that distinguished surgeon. With such results our fear of the abdomen and its subordinate cavity, the pelvis, vanished and numerous advances have been made.

I have already written and published so much on the marked success now obtained in the primary results of abdominal and pelvic surgery, that I am almost tired of saying any more about it, and I fear that I should weary this audience if I resumed the thrice-told tale. What I desire to do to-night is to say something in detail of the secondary results of these advances, of the ultimate success and failures, for it is by these and by these alone that the whole of our work must be judged. The whole profession, every branch of it, has been guilty far too much of rushing into print with new operations and new drugs, announcing, nevertheless, results long before time had made it possible to judge of their permanence and real value. In the case of operations it has been only of late that we have estimated their value by any statistical method at all, and even now our best statistical methods are faulty. We are still too easily contented with seeing our patient safely out of bed, or out of our hands, and then publishing the results as satisfactory. But the results are not satisfactory unless we can say of the operations, or at least of many of them, that years after the events both patients and surgeons were glad that the operations had been done. I fear there is no field of operative surgery from which examples might not be taken of the enthusiastic adoption of new proceedings, followed by their extensive application and final abandonment. The curious feature about the latter process is, that it seems to be generally arrived at by common consent and not by any distinctly rendered professional judgment. It is, in fact, true of operations in a more tangible way and to a more limited extent, as is true of new remedies in the hands of the physician—they come and most of them go without leaving any real good behind them. These latter form no real advance; they

(a) Read Before the Harveian Society at London, March 6th, 1884.

are the preliminary experiments which prove failures, but which are essential in every line of human research previous to the establishment of an ultimate success. To those who criticise our art on account of its slow progress and its many imperfections, I would answer that they ought to read Mr. Darwin's statement of the probable experiments made for the mere result of arriving at our present vegetable food supply, and they will cease to wonder that medicine and surgery are still amongst the arts less than they are among the sciences.

When, therefore, it is claimed for any new departure that it is an advance, it must be established that the secondary results are as satisfactory as those obtained primarily, and that they are permanent. During the last six years several innovations have been at least established, in all of which I have had a considerable, if not a chief share, and for most of these to-night I mean to claim that they are real advances, in so far that their primary results are such as justify them, and their secondary results are satisfactory and permanent.

The first of these is the more frequency of the operation of abdominal section as an aid in diagnosis, and by this I do not so much mean the diagnosis of individual cases as of diagnosis in a general application. Let me give an example: Many years ago I was taught, and then believed, a variety of differential diagnostic signs in pelvic troubles, and by one of the greatest masters of his art. I read then, and I have read since many lectures on parametritis and perimetritis, and I believed I was competent to discriminate between the two and between them and many other conditions. It was only after I had accomplished a large number of abdominal sections for pelvic troubles that I understood how ignorant we had been and still are; and now I peruse lectures on these subjects by distinguished physicians who have never had their finger in the pelvis from above, and marvel that they can talk so fluently on mere guess work. Given a pelvis with a uterus fixed by inflammatory or other effusion, with a mass in front or behind, on one side or both, I say it is absolutely impossible for any man to give more than a guess at the real state of matters inside from a vaginal examination. As to whether it may be advisable to make an accurate diagnosis in another way must be determined by the conditions of each case, but the discussion of this question must be approached only on the understanding that, by the very means upon which alone an accurate diagnosis depends, can there be, in the great majority of cases, anything like an avenue opened up for successful treatment.

Let me give an example of this in detail. The wife of a doctor of medicine was sent to me from a long distance suffering from what had been variously diagnosed as parametritis, perimetritis, pelvic cellulitis, and abscess. She was under treatment elsewhere for many months; had an aspirator passed more than once into the pelvic cavity from the vagina, bringing away serum, pus, and detritus, but she got no better. The whole trouble began in a miscarriage, and from a long detailed history given to me by the letters of her husband, I was of opinion that the case would probably prove to be one of pyosalpinx. But, even after I saw her, I would not and could not give any precise opinion without an abdominal section, for in that way only could an accurate diagnosis be made, and, at the same time, a successful treatment of the case might probably be accomplished. I found the patient worn out with suffering and in constant pain, taking several grains of morphia under the skin every twenty-four hours. The whole contents of the pelvis were matted together, and the uterus quite immovable.

The patient's husband at once accepted my proposal to open the abdomen and deal with matters as I best could. I operated and found above as I found below, the whole pelvic contents, including several coils of intestine, all glued together and completely fixed. After much careful manipulation I succeeded in isolating a mass which

proved to be the right ovary enlarged and riddled with abscesses, originating in the follicles. The patient made a somewhat tedious recovery, yet considering her condition before the operation, it proceeded at a satisfactory rate. Exactly one month and a day from the operation her husband wrote to me, "I was delighted beyond measure when I saw my wife walking down the station platform to meet me, and telling me also how she had borne her journey (a very long one) without fatigue." Her illness had extended over a year, and yet she was cured in a month. The condition found was such that it is a matter of no surprise that all previous treatment had failed. Nothing but the proceeding I adopted could have established the diagnosis, and even before the diagnosis was completed the treatment was accomplished; that is to say, as I did not know, and could not possibly have discovered, that I was dealing with a case of abscess of the ovary till the operation was over, it is absolute nonsense to talk of waiting in such a case till the diagnosis is made before operative proceedings are discussed. The whole merit of this proceeding, which I claim to be a distinct surgical advance, is that the completion of the diagnosis and the completion of the treatment are coincident, both having been alike imperfect and impracticable on previous lines.

I am here met constantly with the objection evident to every one that the indiscriminate employment of abdominal section would be disastrous, and I at once reply that my proposal is not for its indiscriminate employment. As in every other department of our art, each case must be judged on its own merits. I appeal at the outset of the discussion of this point to my primary results, which show that a mere exploratory incision may be made with hardly any risk at all, and that the results of completed operations of this kind have a mortality of less than 3 per cent. The real difficulty lies in the operations which are not limited to mere exploratory incisions, and which are not completed, for these are very fatal, and a large number of those in a list must always mean bad work. In my early practice they were far more numerous than they are now, in fact, amongst the class of cases of which I am now speaking—inflammatory disease of the pelvis, I have not had an incomplete operation, nor a mere exploratory incision for about three years and a half. I speak, of course, in the case of the exploratory incision subject to the correction that I may have mistaken cases truly of this character for malignant disease, but I do not think this very likely. At least, I have heard of none such yet.

Here I must mention what seems to me the great difficulty about the general acceptance and extension of this kind of work. It differs, so far as I can see, from every other kind of surgical work in that it cannot be taught in any kind of way. Any surgeon of average intelligence and manipulative skill, after seeing a few operations for the removal of ovarian tumours may begin to operate with a fair chance of success. At least he can learn a very great deal by watching others operate. But in the removal of a small suppurating ovary, densely adherent to surrounding organs, and covered by adherent intestines, the difficulties and how they are overcome can be seen by no one, not even by the surgeon himself. I cannot in the least describe how it is that I can discriminate by my finger tips between a piece of intestine and the bladder, or a distended tube; between the fundus uteri and an enlarged and adherent ovary. I have felt dreadfully certain, on many occasions, that at last I must have torn a hole in something which would be fatal, and yet the accident has never happened.

The difficulty about teaching is, however, a serious one, for it would seem as if each one who follows me in this work must begin absolutely in ignorance. All that can be seen in my operations is my fore and middle fingers buried in the pelvis, and, after much scratching about, fishing up a purulent tube or a suppurating ovary. Many of my visitors go away grievously disappointed, and I know not how to obviate this difficulty.

Before we discuss the ultimate results of this kind of practice something must be said in answer to several objections which have been urged against it. It has been said that such operations as that I have instanced, and some others, are objectionable because they unsex and sterilise the patient.

The fallacy of the first objection has been so repeatedly exposed that I need not further allude to it. Nor need I take up much time by showing at length how completely sterilised a patient must be in whom the pelvic organs are matted together. The loss of one or both ovaries in her case will make no difference. A woman with an abscess in her ovary or in a Fallopian tube, can no more bear sexual intercourse than a man can read small print who has chronic retinitis. The woman is therefore both unsexed and sterilised by the diseased organs. Their removal restores her sexual powers, and makes no difference in her sterility.

A further and more tangible objection to such operation is made by a recent critic, who says, that some less severe measure than abdominal section should be found for dealing with them. I would answer this by detail, as in the case I have quoted. How could multiple follicular abscesses of the ovary be treated save by removal of the gland? The aspirator was tried and failed. It is impossible to deal with an abscess when it can never be known with certainty that there is an abscess, nor in what organ it is, nor where that organ is, save by abdominal section. In fact the answer is that the diagnosis and treatment are practically concurrent; it is impossible to substitute any other means. I have punctured with the aspirator at the most likely spots and got nothing out, yet I have removed afterwards from the same patient a large pyosalpinx. And even if we were successful enough to hit the abscess, we are all sufficiently alive to the fact that the aspiration of an abscess seldom prevents its subsequent filling; that opening and drainage form the only alternative. I confess that knowing as I do the difficulties of dealing with these cases from above, I could not contemplate with any confidence a proposal for groping at them from below. I cannot see, therefore, how any proceeding at present known to us is likely to supersede that of abdominal section.

We come finally, then, to the question of ultimate success. How have the patients got on for a somewhat prolonged period after their operations? To answer this question I propose to give in prominent detail a series of fifty cases from the work done from 1879 to 1881, in consecutive order as they were originally published, so that any one who has sufficient interest or curiosity may easily identify them. The series includes cases of

Removal of extra-uterine pregnancy	...	1
Abscess of ovary	...	1
Removal of uterine appendages for menstrual epilepsy	...	2
Renewal of uterine appendages for pyosalpinx	...	2
"	" hydrosalpinx	6
"	" menorrhagia	2
"	" myoma	13
"	" chronic ovaritis	14
Opening and draining of pelvic abscesses	...	9
		50

I take fifty cases as a series because it is a sufficiently large number from which to form conclusions, and as the first case was done on March 30th, 1879, and the last upon June 13th, 1881, a sufficiently long interval has elapsed in all of them to justify me in making statements as to the permanency of the results. During the time embraced by this group three deaths occurred, two in cases of removal of the appendages for myoma, the patients having been reduced to the last stage of anæmia by hæmorrhage. The third death was after removal of the appendages for chronic ovaritis, the fatal issues being due, I believe, to scarlet fever poisoning, producing septic peritonitis, which a vigorous employment of the details of Lister's carbolicism was wholly powerless to prevent. This mortality, under six per

cent., was, save in the third case, I believe altogether inevitable, as I shall explain by-and-by.

The first case need not occupy us very long, as it has already been published in detail. It was one of extra uterine pregnancy where the fœtus had died, apparently about the fifth month, and constituted a truly pelvic tumour, which gave rise to very distressing pain. No exact diagnosis was possible, and I began the operation without the slightest idea that the case would turn out one of extra-uterine pregnancy. The patient is now in perfect health.

The single case in the second group is one in which a patient was for years the victim of incessant pain in the pelvis from some cause which she could not determine. Her health was breaking down, and Dr. Lyeott, of Wolverhampton, under whose care she was, placed her under my care for surgical treatment. I found an abscess in the left ovary and removed it. I saw her on the 11th of May last in perfect health and free from pain, an interval of three years after her operation.

The third group consists of two cases in which the uterine appendages were removed for menstrual epilepsy, that is for epilepsy centring round and apparently being produced by the period. The first case had all her life been an imbecile. When menstruation began fits came on, and they gradually increased in severity till she became a furious and unmanageable maniac, requiring the constant care of two attendants.

The Gulstonian Lectures

ON

NEUROSES OF THE VISCERA.

Delivered at the Royal College of Physicians, March 14th, 1884.

By T. CLIFFORD ALLBUTT, M.A., M.D. Cantab., F.R.S., F.R.C.P.,

Senior Physician to the Leeds General Infirmary; Consulting Physician to the Leeds Hospital for Women and Children; and Lecturer on Medicine at the Leeds School of Medicine.

LECTURE III.

GENTLEMEN.—Enteralgia is, perhaps, the most racking torture contained in the curse of mankind; so bitter, so searching is the agony, that more than one sufferer has said to me, calmly regarding his bygone pains, that surely the sting of death had been more welcome. That this malady is one of singular character and marked identity, I had thought it my duty to show at greater length, until I turned but as yesterday to a description of it in Reynolds's "System of Medicine," by Dr. Wardell. In the famous and masterly handbooks of medicine which have been given to the profession of late years, this malady has received so scanty and indistinct recognition, it has been so often confounded with common gripes on the one hand, or contemptuously tossed over to the limbo of hysteria on the other, that Dr. Wardell's clear account of it is eminently valuable.

Before reading this essay, I had also noticed that the two chief points of onset are the umbilicus and the right iliac fossa, or, as I should put it, the umbilical region and the right flank. The central attacks are not strictly umbilical, but arise at a point usually about two inches to the side, generally the right side, of that mark; and the lateral attacks are generally a little higher than the iliac fossa, being nearer the level of the crest of the ilium itself. Another correction I offer is that "females" are not more prone to the disease than "males." My own experience is, of course, inadequate to overthrow an assertion which Dr. Wardell says is "beyond dispute;" for, happily, the disease, if not actually rare, is by very far less common than gastralgia. Gastralgia, I have said, is commoner in women by two to one; but of fifteen marked cases of enteralgia, I find that eight

occurred in men and seven in women. I should add that, out of a far larger number, I have selected the fifteen as severe cases uncomplicated with any intestinal derangement, or with any concurrent troubles elsewhere. The four most grievous instances were all in men of ages between 22 and 48. Cases of mere tormina consequent upon irritation of the bowels or constipation, and cases of lead-poisoning, I have excluded, not because they have no element of visceral neurosis in them, as indeed they have, but because I desired to study the malady in its purest form. In this way, we may hereafter carry our judgment more clearly to secondary or mixed cases.

The greater relative frequency of enteralgia in men than of gastralgia may be explained in part by its being more directly allied to gout than is gastralgia, in part by its dependence on the weightier stress of the affairs of men. From my own cases I gather that a family history of gout, in its heavier and wider operations, is characteristic of enteralgics rather than of gastralgics. Enteralgia, like sciatica, may be a "pure neurosis," but is, like it, not rarely of gouty nature. I gather, also, that enteralgia is aroused rather by the strife of public life than by the teasing of homely worries.

I will cite a few illustrative cases. The Rev. — (No. 54, 1883) is a minister of religion. He has the bright impetuous manner of a neurotic person, and has expended his energies lavishly in his work. He has suffered from no trace of melancholia nor of hypochondriasis; his knee-jerks and other reflexes are normal. (a) For twelve months he has been subject to attacks of pain in the right flank, which are like the stabs and hacking of a knife. The agony is so frightful that he almost longs for his life to be taken. The collapse and subsequent prostration are very serious. Otherwise his health is good, and physical examination fails to discover any disease of parts, or any morbid state of function. Dr. Daly, of Hull, had seen him and had pronounced the case to be one of neuralgia.

Another case of nearly equal severity was also in a clergyman, who made out for me a very graphic story of his malady. In him the seizure began, and the abiding centre of the pain was fixed throughout all attacks, a little to the right of the navel. Intermittently, however, the pain would strike him "in a semicircular course, and settle in the kidney;" or again, would dash from the centre "right through the liver and lodge under the right shoulder-blade." In these seizures occurred then pains obviously spinal, associating themselves with the enteralgia, as pains of the thoracic nerves may ally themselves with gastralgia. There was always incontinence of urine to a painful degree. "The liver and kidney tracks of pain rarely occurred simultaneously. The character of the pain at the centre was as though a spearhead was trying to force itself out from within." The attacks, in this case, have become rarer and slighter in the years 1879-83 than they were in 1876-78. The patient is a man of stirring life and of a lively and genial temperament. After endless medication for "duodenal dyspepsia," he improved on arsenic and on quinine with belladonna. One day, acting under some irresponsible advice, he took an over-dose of "Mother Siegel's syrup," which floored him for a day or two; but after that event he had a long immunity from pain. There are adequate grounds for the belief of all his many advisers that he suffers from undeveloped gout. I may add that, in the earlier years of the pains, they were at times associated with ordinary gastralgia in the severe form.

In the case of Mrs. —, a lady, past the menopause, often sent over to me by Mr. Ball, of York, severe enteralgia has accompanied, or of late succeeded uterine neuralgia of a violent and intractable kind. All the parts of the pelvis and their functions have been normal. She has shown signs of indistinct gout for the greater part of her adult life. Her enteralgic pains were of a

drawing or tightening character, but presented none of the ordinary symptoms of common colic. Sleeplessness and diarrhoea likewise afflicted her, and seemed to spring from the same diathetic cause.

Again, a medical friend writes to me of his own case, that pain in the right flank attacked him during sleep five years ago. It was not very severe, and was relieved by friction and a cordial. Since that time the attacks have been more frequent, more severe, and more prolonged. Indeed, of late, he has never been free from some sense of pain about the same part, and like a woman with a neuralgic uterus he suffers especially if jolted in riding, or in driving over a rough road. Of all remedial means hypodermic morphia alone relieves him. He has suffered from lithic acid in the urine in past years, but not of late; the regulation of diet and use of alkalies having averted that disorder. There is no sign of any local disease.

In the case of a lady under the care of Miss Ker, of Leeds, enteralgic pains set in with a rough periodicity towards the early night. They were preceded by low spirits, irritability, and a distressed expression of face. After times of ease the attacks have been recalled by fatigue or by exposure to cold. They may only return nightly for a week or more, and then disappear for a while; perhaps for nine months little pain would be felt. Bed and hypodermic morphia alone gave her relief. She is much thinner than she used to be. This lady was under my care for gastralgia some years ago. Enteralgia is rarely associated with vomiting, as in gastralgia; but the latter symptom is very prominent in a nurse whom I saw with Mr. Jessop a few weeks ago. It is doubtful, however, whether her case may not be of ovarian origin. Her catamenia are regular and normal, excepting some deficiency in quantity. Her bowels are quite regular, nor do I find constipation more common in enteralgia than we find it to be in many or most cases of atonic disorder.

In Case 320, 1875, the enteralgia was closely periodic, recurring about 3 a.m. during sleep. The patient was a gouty man. Gout also was a marked feature of the family history of a man, set. 53, whose number is 371, 1875. Number 30, 1877, a man, set. 22, was like the last case, but he had suffered from the age of 15 from alternations of gastralgia with definite umbilical enteralgia. Mrs. —, set. 56 (No. 269, 1877), became the subject of like enteralgia after the cessation of migraine, which passed away about the age of 45. The pain in her case was very severe. In another brother and sister, of whom I have seen a great deal, enteralgia in a definite and violent form is the inheritance of the former, and a gastralgia of equal violence and definition, attacks the latter. Both subjects are pure neurotics without gouty history. Miss — (No. 508, 1881), was seen first by Dr. William Roberts, and by him her attacks were called neuralgic, as no doubt they were. The attacks were "like a corkscrew going into her flank (side not noted), and transfixing her." The pain often is so sudden in onset, that she "stands like a statue, flushes, and then turns white, but has no loss of consciousness." Afterwards, "she writhes in fearful pain." There is no periodicity. Her hands and feet, as is usual in visceral neuralgia, are very cold, especially near the attacks. Her appetite, digestion, and bowels are normal, as are all the functions of life. Her lips and gums are well coloured. She presents all the qualities of a neurotic, and her family history is markedly neurotic. Physical examination revealed no defects. This young lady, two years later, thanked me very sweetly for curing her. I find, on turning to my books, that she had a course of bromides and arsenic with pills of quinine and belladonna at intervals. After her recovery, she had married, and continued well. Miss —, set. 46 (No. 618, 1881), had enteralgia arising near the navel. She is a neurotic person, otherwise healthy, and she lost her attacks by transference. She

(a) It is better to state also that I have discussed no case of visceral neurosis in which the knee-jerk was absent.

welcomed indeed a series of violent attacks of right supra-orbital pain with muscæ volitantes, which took the place of the abdominal seizures. The attacks of Mrs. B. (No. 639, 1881), were of the enteralgia type, but were followed by slackened bowels with a little mucus occasionally, though rarely. It is curious that in so many of my cases diarrhoea has been associated with gastralgia, and in so few with enteralgia. On the other hand, as I have said, I rarely find in the latter the constipation, the disordered alvine secretions, the flatulent colic, which is described by other writers, I believe, on grounds of probability rather than of direct observation. Flatulent colic is a wholly different affair; and, as a matter of speculation, I hesitate to place the seat of enteralgia, in the bowel at all. In Mrs. S., æt. 43 (No. 106, 1881), during attacks which correspond to the enteralgia of the other patients, the abdomen is said to become swollen and hard, the aorta throbs, and the heart palpitates; so that some general storm in the sympathetic accompanies the enteralgia, and the flatulence is probably due to that variation. As the attack ceases the abdomen falls, and it was quite soft and normal when I examined. She was cured or relieved by bromides, belladonna and quinine. The case of Miss B., sent to me by Mr. Knaggs, of Huddersfield (No. 274, 1883), presents a good example of the gouty element. Her family history is gouty, and she had podagra at the age of 7. She was subject for many years to facial neuralgia; this left her for twelve months. Then came, and has often returned since, violent neuralgia in the sub-hepatic region. The attacks last three or four hours; and in her, by the way, some vomiting occurs, with little ejection. The attacks are brought on by fatigue, excitement or worry. She never had the faintest trace of jaundice. Rest and change relieve her. She suffers at times from gouty dyspepsia, but in no connection with the attacks. The pulse-tension is normal, the urine of specific gravity 1022; and all organs and functions were normal. Another very similar case was seen by me in the same year; gouty phenomena, migraine, and facial neuralgia having preceded enteralgia. In a young man sent to me by Mr. H. Wright, of Halifax, violent enteralgia was associated with epilepsy, or rather preceded by it. The enteralgia showed a very remarkable periodicity in this case. A curious series appeared after great mental strain and anxiety in a patient whom I saw for enteralgic seizures with Mr. Holmes, of Leeds. First came cervico-occipital neuralgia, with intense hyperæsthesia of the scalp, loss of sleep and appetite, and great debility; then a strange sensibility to cold upon the skin, so that the lightest draught of air distressed him, even the turning of the leaves of his ledger; then periodic coryzas, as intense as if dilute ammonia had been poured over the mucous surface, an abundant fluxion being followed by general prostration; this developed into frequent asthmatic seizures, called forth by cold drinks or by the least change of temperature in his room, but cut short at once by coffee. These symptoms had been relieved by sea-water baths before my visit. I must not linger over these cases, however, many of which do but repeat the symptoms already described. I shall, however, refer to four of them hereafter, which are associated with symptoms on the skin.

Not included in the list now discussed, but naturally following it, comes a series from which I need not quote largely, if at all; but I may indicate, as not uncommon visitors, certain patients who complain of a pain in the region of the hepatic flexure of the colon; I will go further, and say that I believe it to be seated in that place. It is not severe, nor periodic; it is rather wearisome and abiding. It is found in the melancholic rather than in the brisk neurotic; but, like enteralgia, seems clearly associated with gout. Although not connected with obvious disorder of the bowels, yet a course of blue pill and Carlsbad water generally relieves it—a course which would drive an enteralgic subject to a frenzy.

The pain of lead-colic, though probably of immediate nervous causation, is nevertheless not difficult to diagnose from the preceding forms. It has no limited *lieux d'élection*. It is more diffused than enteralgia, and more extended than the pain of melancholia just described. It is periodic, doubtless; but it is rarely an excruciating, rarely a slashing pain; it is rather of a grinding or fretful character. The parallel constipation and other circumstances will, I believe, always serve to distinguish it in those few persons who, suffering from lead-poisoning, have no blue line.

On turning to consider the neuralgias of other viscera, we are met by the difficulty, as yet insuperable, of proving definitely in what nerves the pain may lie. We know that all essays to localise abdominal pains in the splanchnic nerves and their paths to the sensorium, in the sensory fibres around the large arteries, or in the deeper connections of the spinal nerves, are mere gymnastics, barren exercises which may stimulate the fancy, but which as yet can neither be proved nor disproved. We can only find our way through those obscure gates and alleys of the body by patient clinical watchings, by grouping and contrasting our cases, and by noting the curious warps of disease. Are there such affections, for instance, as hepatalgia, nephralgia, and so forth? Careful clinical observers, such as Anstie and Spender, say there are such affections; and with them I am disposed to agree. I have careful notes of three cases in which neuralgia seemed to me to be seated in or near the liver, so far as I could judge by the situation of the pain.

Mr. W. A., æt. 32 (No. 656, 1881), whose health is habitually good, whose habits are temperate, and who presents no obvious disorder of function, has called upon me at intervals for three years. Four months before his first visit, he was taken with a pain which he precisely refers to the seat and extent of the liver. This pain has often recurred, observing no period of recurrence, save that it always attacks him in bed at night. It is a "miserable pain;" he rises, and paces the floor for hours. He maps out the liver, of whose seat he was previously ignorant, with curious exactness. He has had no jaundice, nor does he suffer from constipation. The pain does not stab nor radiate, as spinal pains would do. On bromides and arsenic he recovered, and was well for twelve months, when worry and overwork recalled the attacks. The family history points to rheumatism. I have about five cases in my books similar to this, all agreeing with Dr. Spender's description of typical cases of hepatic neuralgia, in which the patient suffers from severe pain of the neuralgic type, deep in the region of the liver, with no inflammatory symptoms, and with intermissions of perfect ease. In some cases, a characteristic shoulder-pain is present also. Hydrochlorate of ammonia, he says, will cure it ("Relief of Pain," p. 125). Anstie's words are to the same effect, if a little less confident; and he also marks as characteristic a peculiar mental depression which accompanies the pain. Now, I wish especially to point out that the case which Anstie quotes is of a girl, æt. 18, who suffered from repeated attacks of the kind, and that, after one of them, a jaundiced tint appeared, and rapidly disappeared. Subsequently, the pains appeared again without the colour ("Neuralgia," p. 62).

Let me parallel this with the following. Miss — (No. 14, 1882), æt. 22, consulted me for severe pain in the hepatic region, passing towards the stomach. I was disposed to regard the attacks as gastro-duodenal neuralgia. There was decided evidence of neurotic tendencies in the family history, and in her own a liability to nervous diarrhoea. She presented no signs of disordered function. Her complexion was as clear and pretty as her features deserved, and she showed no marks of anæmia. I fear I did her but little good, the attacks recurred, and she sought other aid. But here comes the point of the case; namely, that on some later date she passed a gall-stone with the usual symptoms,

and shortly afterwards she passed a second. Beyond this point, her history is unknown to me. These facts I had from her own medical man. Little as one could dream of gall-stones in a young and clear-skinned girl; in one, too, whose alvine disorders tended rather to looseness than to constipation, and whose habits were alert and active; yet there they were. Again, I saw some months ago, with Mr. Field, of Dudley Hill, a woman of later middle age, whose sufferings were hepatalgic. She had never shown any trace of jaundice, the pains were of a neuralgic type, and she was of the neurotic constitution. Yet, on deep and close manual exploration, both Mr. Field and myself became convinced that there were gall-stones palpably in the gall-bladder. Another case I saw with an old pupil and friend, in which like unaccountable hepatalgic pains recurred, and greatly distressed the patient, also a middle-aged woman. She died some weeks later, of peritonitis due to the perforation of a gall-stone, which was extracted after death. Dr. Anstie evidently took the jaundice in this case to be neurotic; but, put with my own, does not the group of them prove, or strongly suggest, that hepatalgia is, in many cases at least, a sub-hepatic pain arising in the gall-bladder and the ducts thereof, and due either to the irritation of gall-stones or to some vicious quality of the bile? In this way I have explained other cases I have come across, and which at one time puzzled me—cases in which pains of hepatic and epigastric origin recur frequently and violently at times between attacks which are obviously due to the travelling of gall-stones. At present, then, I regard hepatalgia as a pain aroused by the coincidence of an impressionable or neurotic habit with the presence of gall-stones at rest in the gall-bladder. That pain may not arise in these tubes independently of such or similar irritations, I will not, of course assert.

The same reflections occur to me when I pass on to consider nephralgia. Anstie suspects that many cases of so-called nephralgia have been cases of pain lying more outwardly. In such a sceptical spirit, I minutely searched into the following case. A lady, æt. 41 (No. 528, 1881), was sent to me by Dr. Charles Smith, of Halifax. Two months previously, after great harass, she woke at 5 a.m. with intense pain in the loins, chiefly on the right side. It was dreadful pain; her aspect became death-like, her finger-nails black, and her lips ashen. Thus she suffered for three mortal hours. The pain also ran round the front of the abdomen on the same side and down the groin into the thick of the thigh. Her micturition was frequent for some hours, and it then fell away to scantiness and rarity. The same series of pains recurred every morning at the same time, though happily with less severity, and slight degrees of it were felt occasionally at other times. Both Dr. Smith and myself sought in vain for any gross cause for such attacks; the only discovery made was of some grey sandy matter of an indefinite kind in the urine. Dr. Smith says: "I never could satisfy myself that there was a calculus in her kidney. When she gets below par, she still has returns of the renal pains, with the same flow and ebb of the urine." "I suppose," he adds, "a visceral is like a facial neuralgia, which, when due mostly to a condition of nerve, is called a pure neuralgia, when mostly due to a condition of tooth is called tooth-ache, but in a large mass of cases is caused by a condition of nerve not bad enough to show itself if not irritated by a condition of tooth. In this category comes no doubt Mrs. —'s case—a nephralgia due not entirely to nerve, but coming partly from the kidney having to perform abnormal work. I wonder whether a neuralgia of the kidney could produce swelling of the testicle, not the epididymis. I have seen a case which I could only interpret thus." I have quoted Dr. Smith's remarks in full, as they apply so well to the mixed cases of gastric and other neuralgias I have tried to interpret on like principles. That in Mrs. —'s case, the conditions of nerve predominated seems probable, because she

was a highly nervous woman, and had suffered from other forms of neuralgia, because the attacks showed periodicity, and because no other considerable cause was found.

The small quantity of fine gritty matter seen occasionally in the urine seemed, however, in some of the attacks to be the *causa efficiens*.

Another case is No. 384, 1883. Mr. —, æt. 27, has suffered at times for three or four years from pain in the region of the right kidney, and at times very severely. The pain is then a continuous ache, with exacerbations; it runs, when more acute, down the track of the ureter to, or nearly to, the bladder. At times, its severity causes cramps of the limbs and collapse. There was never a trace of blood, and the differential diagnosis from calculus was carefully considered, and decided against calculus. The urine was wholly negative, not even unduly acid. He improved upon quinine and belladonna.

No. 394, 1882, was a commercial traveller, æt. 39. He suffered precisely as No. 384; and the two cases received much attention from me, as they came within a few days of each other. This patient had also neuralgia of the left orbit and cervico-occipital neuralgia with Valleix' points. There was no syphilis, by the way, in any of these cases.

Before dismissing the subject of the kidney, I may remark, that, in chronic renal disease, in granular kidney especially, gastralgia may appear with its craving appetite, sensations of want and so forth, as in the uncomplicated form. I think this has been spoken of by previous writers, and so also has the concurrence of gastralgia with aortic regurgitation. This coincidence I had failed to verify until recently, when three well marked instances came under my observation.

(To be continued.)

NEW SURGICAL NEEDLE AND THREAD.

By JOHN WARD COUSINS, M.D. Lond., F.R.C.S.,
Surgeon to the Royal Portsmouth Hospital.

A VERY simple innovation, in which the ordinary steel needle is superseded by converting the end of the wire into a needle. The wire is cut into equal lengths, and each piece is separately reduced by drawing, with the exception of an inch or two at one extremity. The end is then converted into a convenient needle by pointing and burnishing.

This little invention offers several advantages in many surgical applications. The needle is always new and clean, and it can be used only for a limited number of sutures. It requires no preparation or threading, and the continuity of the needle and the ligature prevents the delay in introduction which often occurs with the ordinary needle from kinking or twisting at the eye. The point is always perfect, so that the pain of penetration is considerably reduced. Damaged needles are instruments of torture; and even in these days of antiseptic surgery I have found them carefully preserved in pocket cases ready for any emergency! The chief purpose of this little invention is to prevent unnecessary pain, and to provide a needle with a perfect point, which can be used only in the introduction of eight or ten sutures, and then thrown away for ever. It is, moreover,

especially adapted for the immediate surgery of the field of battle.

In my hands nicked steel wire has proved an excellent metallic thread for closing skin wounds, and in consequence of its peculiar rigidity it requires only one turn of the ligature to secure the edges in perfect apposition. It admits also of very easy removal, and this is a great advantage, for the "taking out" of the thread is often a more painful operation than its introduction. The single turn of the wire should be made on one side of the wound, over the point of penetration, and the ends evenly bent down. For the painless removal of the suture, the loop should be first unfastened, then, while holding with the left hand one end of the wire, the other end should be straightened out and cut short; the thread now can be easily withdrawn.

The surgical needle and thread is manufactured by Messrs. Maw, Son, and Thompson in several convenient sizes from nickel steel and silver wire. The steel needles are made both straight and curved; the silver needles are tipped with steel and flexible, so that they can be bent to any shape, and are thus especially adapted for many plastic operations. To protect the point from accidental injury, each needle is supplied with a shield of fine straw.

Clinical Records.

IMPERFORATE ANUS—OPERATION—DEATH.

Under the care of Dr. G. DE GORREQUER GRIFFITH,
Late Senior Physician to the Hospital for Women and Children.

Reported by Miss EGER.

Mrs. —, æt. 20, was married October 1882. Became pregnant May 1883; and in the following month was deserted by her husband, in consequence of which she has been in great mental distress during the whole of her pregnancy. In October last she came up to London to be with her sister during her confinement, on the journey she received a shock from the falling of beams of wood close to her. Labour began February 2nd, 1884, 12 p.m.

February 3rd, 10 a.m.—She was attended by two of the pupils, Miss K. Bose and Miss A. W. Eger. At 12.15 p.m. was delivered of a full grown, well nourished child. Patient appeared to be in a very melancholy state, the expression of her face was anxious and distressed; she could not be roused or interested even after the birth of the child. Child was born with snuffles, and a discharge of mucus from the nostrils which quite prevented suction; ordered to be fed by spoon with one part of milk in two of water.

4th, 10 a.m.—Snuffles very bad, great dyspnoea, food had regurgitated through nostrils. No urine or meconium had been passed, so was put into a warm bath which induced a flow of urine but no meconium. On close examination found imperforate anus, there being no bulging whatever in the perineum, nor any appearance whatever of anus. The child was seen in the evening by Dr. Griffith and Dr. A. Routh; both concurred that more than a membrane covered anus, but that it would be advisable, unless symptoms became urgent, to wait, guided by circumstances, in order to give time for a bulging of the intestine at the usual site of anus, if such were possible to take place.

5th, 9 a.m.—Found child suffering from great dyspnoea, abdomen tympanitic, and scrotum cedematous; the urine which was passed was very deep coloured; meconium had been vomited through mouth and nostrils during the night, no food could be retained, the lower extremities were blue and cold, no bulging at perineum. As the mother was willing, and the child was in such evident distress, Dr. Griffith thought it advisable to operate at once.—10 a.m. Chloroform was administered which the child bore well. Dr. Griffith first made a perineal incision at the usual site of the anus sufficiently large to admit the tip of forefinger, and carefully dissected upwards with the handle of knife, and nail of little finger, taking as his guide the curve of the sacrum, till he came into the pelvic cavity and beyond the brim; not finding any trace of the rectum, and meeting with nothing that seemed like the bowel, considering that nothing would be gained by venturing further, he decided to open the intestine through the abdominal wall, and therefore placed an oil plug in the perineal wound to arrest the slight hæmorrhage which resulted from the cut he

had made. He then performed lumbar colotomy, or Amussat's operation, the incision being made below the twelfth rib on the left side where there was a bulging of apparently distended intestines; the gut was fixed to abdominal walls by silver sutures, and an opening made into it, through which flatus and meconium passed freely, the opening being large enough to admit tip of little finger. The wound was covered with lint, and the child placed on its back.—12.30 p.m. Breathing greatly relieved, did not appear to be in pain, meconium still passing through artificial anus; vomiting continued when fed, probably partly due to the administration of chloroform during operation. The lumbar wound was cleansed thoroughly with warm water, no urine had been passed.—3.30 p.m. Wound again cleansed; as vomiting continued, was ordered to be fed every twenty minutes with one teaspoonful of milk and water in same proportions as before.—6.30 p.m. Very little meconium had passed since last visit, and a small piece of mucous membrane of gut protruded into the opening, —ekversion of the mucous membrane—at outer or posterior extremity of incision. Dyspnoea and snuffles not noticeable; had not vomited for two hours, has been fed every twenty minutes. Temperature 97° F.; wound redressed.—9.30 p.m. Seen by Dr. Griffith, who considered the case progressing favourably, no urine passed yet per urethram. Wound redressed with vaseline.

6th, 8 a.m.—Had passed urine plentifully of a dark colour, slight convulsions during the night, no vomiting, small quantities of food being given at a time, and frequently repeated, as above ordered. Around the lumbar wound is a slight ring of adhesive inflammation, the opening is partially closed by the protrusion of mucous membrane as before named, but the bowel seemed to have become adherent all round the abdominal opening, very little meconium had passed during the night; breathing easier. Bathed wound, and applied water dressing. Tried to remove plug from perineum, but it had become firmly fixed.—10.30 a.m. Dr. Griffith ordered linseed poultices to both wounds to relieve the tumefaction of intestine, to keep the artificial anus from being blocked, and to soften plug in perineum; laid the child on the left side.—12.15 p.m. Child seen by Dr. Griffith, who said he would enlarge the lumbar opening at 4 p.m. if the swollen mucous membrane still projected, and ordered the poultices to be continued; the child was in every respect doing well.—4 p.m. Child in state of collapse had been convulsed during the afternoon, appeared to be dying. Dr. Griffith did not think it advisable to do anything further.—6 p.m. The child died.

Post-mortem.—Found the lumbar opening had been made into descending colon which terminated in a cloaca, that was common to the bladder and to the bowel; the cloaca —being the common receptacle for the faeces and urine—was pear-shaped, the narrow tapering extremity being at the pubis, the broader being above, where the bowel was continuous with it; this common viscus lay above and in front of the perineal wound.

The whole of the intestines were cut out and sent to Mr. Cooke for further and more minute examination.

The General Medical Council.

THIRTY-FIFTH SESSION, 1884.

President, Dr. AGLAND, F.R.S., in the chair.

SIXTH DAY.—MONDAY, MARCH 31st.

THE SCOTCH CONJOINT SCHEME.

THE Council resumed consideration of the motion of Dr. Haldane approving the proposed co-operation between the Colleges of Physicians and Surgeons of Edinburgh and the Faculty of Physicians and Surgeons of Glasgow.

Dr. HAUGHTON said he had at the previous meeting of the Council moved the adjournment of the debate because he had not felt himself sufficiently master of the scheme to be able to say whether he approved of it; but since reading it carefully, he approved of the first two clauses embodying the principles of the proposed combination. The great defect in the old Scotch scheme was that only two bodies were engaged in it, and that those bodies reserved the power of giving certain diplomas. Under the present scheme three corporations com-

bined instead of two, and all of them surrendered the power of giving single diplomas. He objected to the clause enabling either of the contracting parties after five years to give notice of withdrawal from partnership. That he thought to be a blot on the scheme, and that the same defect characterised the English scheme. He would propose the insertion of some additional words, to the effect that before any proposition was made to dissolve the partnership the case should be submitted for the opinion of the General Medical Council.

Dr. QUAIN advocated postponing consideration of the scheme pending Parliamentary action. The Council having expressed an opinion in its favour, it was hardly right to bring forward a proposal of a new kind, which suggested that the Council did not believe that there was any possibility of the Bill being passed. It would be inconsistent for the Council to sanction, under present circumstances, separate schemes like those proposed.

Sir H. PITMAN moved as an amendment, "That the question of approving the scheme of conjoint examinations proposed by the three Scotch corporations be not considered in the present session of the Council." As a Bill was at present before Parliament, he submitted that in sanctioning any individual scheme the Council would be placing itself in an attitude of opposition to the Government, and he thought it would be sufficient if the proposed schemes were entered upon the minutes.

Dr. HUMPHREY, in seconding the amendment, said he did not express any opinion as to the merits of the Bill before Parliament or of the schemes submitted to the Council. His reason for seconding the amendment was that the scheme would be entirely invalid if the Bill passed, and they could only enter upon its consideration on the supposition that the Bill would not pass. If the Bill should not pass, it would then be the duty of the Council to reassemble and take into consideration any proposals that might be brought before it in the required direction.

Dr. DUNCAN thought the Council ought to sanction the scheme without reference to any Bill before Parliament. He protested against the unholy alliance between the corporations and the universities, which in their history and in their objects were entirely different bodies. The universities were established for the purpose of promoting religion, morals, and learning, and they had nothing to do with the medical profession as such. The corporations were formed simply to look after medicine, with which the universities had nothing to do. If the Bill passed, he should be for the first time ashamed of his profession. The great object to be desired was that no one should get upon the Register without a complete qualification, and that would be secured by the Scotch scheme proposed by Dr. Haldane.

Dr. HAUGHTON said he had suggested to Dr. Haldane that he should modify his motion by prefixing to it the words "subject to the future directions of the General Medical Council," and that Dr. Haldane had acceded to that suggestion.

Dr. STRUTHERS protested against an abrupt termination of the discussion after it had been commenced, as proposed by Sir Henry Pitman.

Mr. MACNAMARA thought the Council would be guilty of a dereliction of duty if it did not take the system into consideration. He hoped that Dr. Pitman's proposal would be negated, and that the Council would express its views of the scheme one way or another.

Dr. STRUTHERS thought Sir Henry Pitman's amendment was a high-handed proposal to stop an important discussion. In his long experience he did not know any more important proposal that had been submitted to the Council; and whether the Council approved the scheme or not, it ought to be thoroughly discussed. No important purpose could be served by suppressing discussion, and the Council would place itself in an awkward position by its refusal to consider the question. He desired to express no opinion on the subject of the Bill, but he maintained that it was the business of the Council to do its duty, irrespective of any proposal which might be brought forward by the Government. It was stated that the scheme, if approved, might interfere with the Medical Bill. That was an admission that the scheme was so good that if it had the approval of the Council there would be no occasion for medical legislation as far as Scotland was concerned. He was surprised to hear the statement that the Bill would supersede the proposed scheme. He did not know a word in the Bill that was incompatible with the scheme, and he denied any such incompatibility.

Mr. TRALE thought it would be better to have a special meeting to consider the English and Scotch schemes.

Dr. P. HERON WATSON thought that the Council ought to consider any well-conceived scheme brought before it for the amalgamation of any of the bodies. He hoped that the scheme would be sanctioned and come into operation immediately. The Colleges had no *arrière-pensée*; they had burnt their ships, and had no intention of going back upon the single qualification. The Council ought to sit as long as was necessary to inquire into the details of the scheme, and not allow their own private convenience to interfere with the performance of duties imposed upon them by Act of Parliament. They had heard from a very distinguished Fellow of the College of Surgeons why the English scheme of 1877 had not come into operation, and if the Council now refused to consider the question after what had occurred, it would be believed that the representatives of the English bodies had declined to discuss it for reasons of a similar kind.

Dr. BANKS believed that the scheme was in the right direction, and had no doubt that Ireland would follow the example that had been set.

Dr. SCOTT ORR said he could not support Sir Henry Pitman's amendment. The Scotch authorities had again and again endeavoured to formulate a conjoint scheme, but they had found it impossible to unite the universities with the corporations, and he believed the same difficulty would always exist. He was delighted to hear that there was a possibility of amalgamation between the universities, and he hoped that the scheme of the corporations would meet with the approval of the Council.

Sir HENRY PITMAN, in reply, said he adhered to his amendment, believing that that was not the right time for the consideration of a conjoint scheme whatever bodies might bring it forward. He was surprised to hear the statement of Dr. Struthers that the Government Bill would make no difference in the Scotch scheme. According to the scheme there were to be three examinations, but if the Bill passed that arrangement would be upset. He thought it would be far more prudent to postpone the consideration of the subject to another meeting of the Council.

The amendment was then put and rejected; 8 voting in its favour and 11 against.

On the original motion being put from the chair,

Dr. WATSON explained that Clause 15 of the Scotch scheme, providing that either of the parties to the arrangement should be at liberty after five years to give notice to terminate it, had been inserted on legal grounds, and that but for its insertion either of the parties could at any time appeal to a judge in court to have the whole concern broken up. If the scheme worked for five years, there was every prospect of its future continuance, especially as everything would be under the direction of the Council.

Dr. STORRAR asked whether the scheme included any plan for conducting systematic preliminary examinations in arts.

Dr. WATSON said it was intended to carry out loyally the instructions of the Council in preliminary examination.

Mr. SIMON said he could not support the motion while a Bill was before Parliament proposing what he believed to be a far better scheme than that submitted by the Scotch bodies. The scheme of the Bill was in principle the scheme of the Council—the scheme for combining all the authorities in each division of the kingdom. It would be deplorable in the interests of medical education if the universities did not take part with the corporations in providing a single security for the qualification of the licentiates. He was not content with a scheme that combined only three corporations. The Council had voted again and again on the subject, and it was now for Parliament to decide what should be done.

The motion was put and carried by a considerable majority.

The Council then adjourned.

SEVENTH DAY.—TUESDAY, APRIL 1ST.

THE MEDICAL BILL.

Mr. MACNAMARA moved, "That this Council do resolve itself into a Committee of the whole Council for the consideration of the provisions (other than those directed to the reconstruction of the General Medical Council) contained in the Medical Acts Amendment Bill, as amended in Committee of the House of Lords in the present session of Parliament."

He thought it would be unworthy of the Council to discuss any question involving its own existence or non-existence, and hence the words in his resolution, excepting questions concerning the reconstruction of the Council. He had no intention to put himself into a position of antagonism to the Government, which indeed he desired to strengthen in its efforts to pass the Bill, with some few modifications. The Council had been the subject of constant abuse, and its powers of "moral suasion" had been ridiculed, but it was through those very powers that the examinations of the various bodies (he alluded especially to Scotland) had been improved. With reference to direct representation the most distinguished members of the Council had already expressed themselves against it, and when he remembered the important duties of the Council in regard to education, he could not conceive that a country practitioner would be a better representative than any of the distinguished members who now composed that body. The agitation was but a journalistic one, got up by parties who sought by direct representation to get access to the Council chamber. He protested against the charge of self-interest which had been made against the medical bodies in the attitude they had taken. The body which he represented had no such motive. All its efforts had been in the direction of medical education and it had done noble work in that direction; and he believed the same might be said of the other Colleges. He thought that an amendment should be introduced into the Government Bill by which the receipts of the three Branch Councils should be thrown into a common fund and then divided *pro rata*. By the existing arrangement the English Branch Council received a large amount for the registration of students, whose qualifications were Irish and Scotch. On the subject of affiliation, he thought that it should take place not at the end, but at the commencement of medical study. Such a mode of affiliation had not been discussed by the Royal Commission. He believed that the existence of his own College was in peril in consequence of the present Bill. The new licentiates would be contented with the bread-winning qualification (as was the case with the large majority of the present practitioners) and would not seek the Fellowship of the Colleges. It had been suggested that the Colleges could recoup themselves by their primary examinations; but he begged the Council to remember that those examinations were at present conducted by the Royal University at the charge of a guinea only for each student.

Mr. COLLINS, in seconding the motion, protested against the exclusion from the divisional board of the Society of Apothecaries of London and the Apothecaries' Hall of Ireland. He also expressed a belief that the Bill would lower the status of all the bodies and would interfere considerably with their income.

Dr. STRUTHERS said the Bill was often brought forward as being "on the lines of the Royal Commission," but he reminded the Council that the Commission was not unanimous, and that there was a minority report, which he thought might satisfy the profession better than the majority report. He could not reconcile himself to the sweeping away of all the existing and time-honoured degrees in the country. All that was wanted for the public was a complete education and examination; and by the proposed system of coadjutor examiners, say from the divisional board, that object would be fully attained without disestablishing existing qualifications. The principle of the Bill would not be affected by such a method. He did not think that the Government had been well advised. It was giving offence all round, and threatening a general revolution among the bodies. He did not believe that the combination of universities and colleges would work practically. In the great English scheme of 1877 there was no university co-operation. The examining board was limited to the corporations. That could not be tolerated in Scotland, where the universities were large, active medical schools, which would not abdicate their functions, and would not tolerate the imposition of an additional examination on their students. He then proposed the following amendment:—"That the Council take into consideration the question whether the object of the Medical Acts Amendment Bill now before Parliament, in so far as completeness and sufficiency of examination and admission to the Medical Register are concerned, can be obtained with less disturbance of existing arrangements than will be occasioned by the method proposed in the Bill."

Dr. PETTIGREW seconded the amendment.

Dr. QUAIN said that the conjoint schemes originated in

the fact that there were nineteen licensing bodies giving between fifty and sixty different qualifications, and that students rejected by one of those bodies often went and obtained the licence of another. In the English conjoint scheme the universities as well as the corporation joined, their only desire being to benefit the public; but it was not persisted in simply because the Scotch and Irish bodies had not followed the example. Legislation was an absolute necessity. He had been a strong advocate for a conjoint scheme to keep out Government control, but Government control was really required under present circumstances to prevent the gross scandals which existed, and which the chairman of the Royal Commission had said could not be allowed to continue. The Irish and Scotch bodies had been the source of all their trouble. If they did not accept the Bill, there would be a board of examiners like that for the army and navy; the Government would have a special board, and would wash its hands entirely of the corporations and the universities.

Dr. HAUGHTON opposed Dr. Struthers' amendment, believing that it was now too late to refuse to accept the principle of the Government Bill.

Dr. HUMPHRY said he did not think that the English universities would look with favour upon coadjutor examiners appointed by other boards. They would regard such a measure as an indignity. The universities did not regard their degrees as mere licensing qualifications. Nor would the universities be willing to accept the conjoint examination as qualifying for their degrees.

Dr. WATSON maintained that the Council would be justified in taking up the consideration of the Government Bill. He thought that the Government had shown but scant courtesy to the Council in not sending the Bill to it for its opinion; and he regretted that there should be any attempt to burke discussion on the subject. He denied the existence of "gross scandals" such as to justify the Government measure. The agitation for it had originated entirely with the London medical journals. The only opportunity which the members of the Council had of gaining the ear of the profession was that afforded them at the meetings of the Council, and even then they were exposed to the possibility of what they said not being reported in the journals, which only reported as much as suited their own purpose. He should propose on a future occasion the publication of an official report of the character of "Hansard," in order that they might not be dependent on the journals. He supported Mr. Macnamara's motion.

Dr. PETTIGREW thought that the Scotch universities should be encouraged to combine, and thus do away with the necessity of legislation.

Dr. STRUTHERS asked permission to withdraw his amendment, which was granted, and it was accordingly withdrawn.

Mr. MACNAMARA's motion was then put, and it was carried by a majority of 11 to 9.

THE REGISTRATION FEES.

Mr. MACNAMARA (the Council being in committee) again called attention to the large sums received by the English Branch Council for the registration of practitioners holding only Irish and Scotch qualifications, and proposed that the surplus funds should be divided *pro rata* between the three divisions of the kingdom. The sums received for fees should be capitalised and handed over to the Medical Council, as contemplated in the Bill, according to which the surplus funds were to be devoted to "the general purposes of the profession." A clause should be introduced into the Bill providing that the surplus fund should be apportioned to the divisional boards of each division of the kingdom, by whom they could be applied to the general purposes of the profession. The divisional board in each division of the kingdom would know more of the requirements of that division than the Medical Council could know, and would be better able to apply the surplus funds judiciously. The Royal University in Ireland had declared that it would not ask for any share of the surplus; but in repeated conferences between the Colleges of Physicians and Surgeons it had been proposed to divide the surplus funds of the conjoint examination into eighths, giving five-eighths to the College of Surgeons and three-eighths to the College of Physicians. He should be surprised if the proposal he had made met with any opposition, as it was based on the principle of fair play to the three divisions of the kingdom.

Mr. SIMON said he had not voted against going into committee on the subject (although he had a very strong objection to the proposal), as he desired that Mr. Macnamara should have an opportunity of making his statement as to what he regarded as objectionable in the Bill. His proposal seemed a reasonable one. He (Mr. Simon) thought that the money clause referred to was a bungling one and capable of improvement. The matter, however, was not one for the formal consideration of the Council, and he would suggest that Mr. Macnamara's best course would be to associate himself informally with one or two business members of the Council who could come to an agreement as to the right course to be adopted, and there would be no difficulty in getting their views communicated to the Government.

Dr. QUAIN thought that registration was no fit test of the proportions in which the funds should be divided, but that the proper test would be the number of practitioners.

Mr. MACNAMARA said he had no objection to refer the matter to a committee; and after a short conversation this course was agreed to, the committee consisting of Dr. Haughton, Mr. Macnamara, Dr. Haldane, Dr. Watson, Mr. Marshall, and Dr. Humphry.

The Council then adjourned.

EIGHTH DAY.—WEDNESDAY, APRIL 2ND.

THE MEDICAL BILL.

The adjourned consideration of the provisions of the Medical Acts Amendment Bill was resumed, and a report was presented by the committee appointed, on the motion of Mr. Macnamara, with reference to the money clauses of the Bill. It recommended "That any surplus appearing on such accounts to be remaining after leaving a sufficient balance for the payment of current expenses shall be disposed of by the medical board for the maintenance of the above-mentioned medical authorities."

Mr. MACNAMARA moved the adoption of the report.

Dr. HAUGHTON seconded the motion and contended that the proposal to hand the surplus funds over to the Medical Council, as proposed by the Bill, was inequitable. Dr. Haughton added, in answer to an inquiry by Dr. Struthers, that "the above-mentioned bodies" referred to in the report were bodies that supported libraries and museums out of their examination fees.

Dr. STRUTHERS opposed the motion.

Mr. MACNAMARA said that the universities (who were entitled to have their pupils examined on the payment of fees) would have contributed no money to the fund, and would, therefore, have no claim upon it.

Dr. STRUTHERS, after some further discussion, moved an amendment that for the word "Council," in line 17, p. 21, of the Bill, the word "board" be substituted.

Dr. PETTIGREW seconded the amendment.

Dr. HUMPHRY maintained that the question concerned all the universities in the kingdom, not the Scotch universities only. The universities did not contribute to the fund, and therefore had no claim upon it. He hoped that the Council would adopt the recommendation contained in the report.

Dr. LYONS thought that the Council would be placing itself in an awkward position by adopting the report, because it would be naturally supposed that it approved the rest of the Bill. He would suggest that the subject be referred back to the committee, who should be requested to report again upon it at the next meeting of the Council.

The amendment of Dr. Struthers was put and negatived.

Dr. LYONS moved another amendment, that the question as to the adoption of the report be taken into consideration that day six months.

Dr. STORRER seconded the motion, which was supported by Dr. CHAMBERS and opposed by Dr. HAUGHTON.

Mr. SIMON proposed that the Council should express its approval of the report, and its opinion that the corporation might with advantage address Her Majesty on the subject.

The amendment of Dr. LYONS having been put and negatived, Mr. MACNAMARA expressed his willingness to accept Mr. Simon's proposal, which was put from the chair and adopted.

Mr. MACNAMARA then proposed that the Council should again go into committee on the subject of the Government Bill.

The motion was seconded by Dr. WATSON, but was negatived by the Council.

Dr. HALDANE moved "That it be remitted to the Executive Committee to consider whether the experience of the General Medical Council during the last twenty-five years suggests any details which might be introduced with advantage into the Medical Acts Amendment Bill, and that they be authorised to communicate with the Council Office on any such suggestions."

The motion was seconded by Dr. DUNCAN, and agreed to.

Dr. STORRER moved, "That in Clause 9 of Chapter IX. of the General Council's standing Orders, the following changes be made:—Instead of 'the General Council shall pay one-fourth, the English Branch Council shall pay one-fourth, the Dental Fund shall pay one-fourth,' the following be substituted:—The General Council shall pay three-sixths, the English Branch Council shall pay two-sixths, the Dental Fund shall pay one-sixth."

Dr. AQUILLA SMITH seconded the motion, which was supported by Dr. QUAIN, and carried.

Dr. QUAIN moved, "That the Executive Committee be empowered to take such steps as they may be advised to adopt, with a view to improve the structural arrangements of the Council-room."

A discussion followed with reference to the defective ventilation of the Council-room, and ultimately it was referred to the Executive Committee to consider the subject and report to the Council.

THE TIME LIMIT IN EXAMINATIONS.

Dr. CHAMBERS moved, "That it is expedient that any candidate at his final oral examination for a diploma should be rejected unless he shall have been examined orally for at least half an hour by the examiner, or by each of the examiners, on whose authority he has been deemed deficient in requisite knowledge or skill." He alluded to the complaint of the public of the insufficient number of medical men, and to the belief that many candidates were rejected who ought to have been passed. Great complaints, he said, have been made that students who had been considered intelligent and industrious ran a great risk of being plucked at the Pass Examinations. It was hardly a matter of surprise to him that under such circumstances the public should think that there was something wrong in connection with the examinations. At the Royal Colleges of Physicians and Surgeons of Edinburgh the percentage of rejections was 41, and at the College of Surgeons, England, 37; the percentage decreasing with the other bodies down to as low as 22. The greatest number of rejections took place where the examiners were most limited in point of time. He maintained that an examiner ought not to be strictly limited, but should be able to pass a candidate as soon as he had satisfied himself as to his competency, but ought only to be allowed to reject him after a complete examination for the full period. There had been a great change in the character of examinations in recent times with regard both to the quantity and quality of the knowledge required. At the College of Surgeons of England 5 per cent. of the candidates were rejected at the written examinations, which were conducted in a leisurely way, and 33·7 per cent. at the oral examinations, which were very rapid. Some change was absolutely required in conducting the examinations.

Mr. TEALE seconded the motion.

Dr. DUNCAN said he was strongly opposed to the proposition and disagreed entirely with the remarks of Dr. Chambers. It was not generally the nervous man who was rejected, but rather the bold, brazen-faced man. The nervous man was always dealt with as such, and the consideration he received sometimes led students to pretend to be nervous in order that additional favour might be shown to them. The difficulty with examiners was not with the good or the bad candidates, as to whom a decision could easily be arrived at, but with the students of the middle class. He protested against anything like an injudicious interference with the liberty of the boards, which would be the result of passing Dr. Chambers' motion. The best judges were the universities and corporations, who might not unreasonably tell the Council to mind its own business, and decline to carry out such a recommendation.

Mr. TEALE thought that the present was an opportune moment for raising the question. The heavy lists of rejections showed that the various bodies throughout the kingdom were doing their duty in not competing downwards against one another; but the question had another side. It was important to ascertain whether the large number of rejections that took place was absolutely necessary, and whether it indicated a great amount of unpreparedness on the part of the students. Mr. Teale called special attention to a resolution

passed by the Council recommending in oral examinations, notwithstanding any general rule providing a limit of ten minutes or a quarter of an hour, that there should be a margin of additional time for satisfying the examiners in doubtful cases.

Dr. SCOTT ORR said it was rather the middle-class man than either the good or the bad man that required the time. He thought there should be no limitation of time for the examination of candidates; there was no such limitation in Glasgow.

Dr. HAUGHTON said that the proposed rule would greatly surprise the University of Dublin; it applied to a method of examination which was unheard of amongst them. He thought the resolution an impracticable one.

Mr. SIMON said the motion was, in his opinion, highly objectionable. He did not consider that ten minutes was in all cases necessary to satisfy an examiner absolutely that a man was unable to pass. It was doubtful cases that required the time, which might extend to half an hour, or even an hour. A hard-and-fast rule that at least half an hour must be given would be just as faulty as the rule of the College of Surgeons that the examination should be ten minutes.

Mr. MARSHALL said that at the Royal College of Surgeons of England they contended that the decisions of their examiners did not contain an element of doubt. If every candidate were to have half an hour, the rejections would be much about the same; and then there would be a demand for a half, or perhaps even an whole hour. He trusted that the Council would not pass the resolution, but would content itself with what was a really good resolution passed two years ago. The Council must rely on the honesty of the examiners, whose task was a difficult one.

Dr. LYONS thought that the discussion had accomplished a very useful purpose, but as there might be a question as to the expediency of passing the resolution, rather than it should be negatived he would suggest its withdrawal.

Mr. MACNAMARA said the Council was effecting a complete change of front. Formerly its efforts were directed to securing the rejection of incompetent candidates, but now it seemed to be going in the opposite direction.

Dr. WATSON said it was not correct to say that the final examination of the Scotch bodies were for ten minutes each. In surgery and surgical anatomy they were forty minutes; in medicine, forty minutes; midwifery and medical jurisprudence, twenty minutes each; while in clinical surgery and medicine the periods were practically unlimited. It was also the custom whenever there was the slightest feeling of doubt on the part of the board of examiners, to send the candidate back to be re-examined by fresh examiners who might be supposed to deal with the case impartially.

Dr. CHAMBERS then, by leave of the Council, withdrew his motion.

UNQUALIFIED ASSISTANTS.

It was resolved, on the motion of Dr. Chambers, "That the Executive Committee be requested to communicate afresh with the Lord President of the Privy Council and the Registrar-General, with a view to the enacting such provisions as were suggested by the Council in its last session to prevent the delegation by registered practitioners to unqualified persons of duties strictly professional, and to prevent also the signing of misleading certificates of causes of death by unqualified assistants."

Sir HENRY PITMAN then moved the following resolution: "With reference to the fact, adverted to from the chair at the opening of the present session of the Council, that Dr. Acland's term of office as President will expire on the 18th of July next, the Council requests Dr. Acland that, if the Council shall not be sitting at the time when his term of office expires, he will favour the Council by remaining in office as President till the Council shall next afterwards assemble."

Dr. HAUGHTON seconded the resolution, which was unanimously agreed to.

The PRESIDENT, in responding, said, it would be desirable in the event of the Medical Bill not passing that the Council, with its new President, should meet in the autumn, in order to undertake the serious duty of deciding what it was to do after five bills had been passed through one branch of the Legislature and withdrawn in the other. If, on the other hand, the Bill should pass, we would then confer with his colleagues on the Executive Committee as to what course should be pursued in order to carry out the provisions of the new Act.

On the motion of Sir HENRY PITMAN, a communication from the College of Preceptors was entered on the minutes. The communication, dated March 27th, stated that at the recent preliminary examination for medical students and others the number of candidates was 230, of whom 55 obtained certificates qualifying for registration as medical students. The results were stated to be very unsatisfactory, only about a fourth of the candidates having satisfied the requirements of the Medical Council.

This concluded the business of the Council, and after the usual complimentary resolutions had been passed, the session was brought to a close.

Transactions of Societies.

CLINICAL SOCIETY OF LONDON.

FRIDAY, MARCH 28TH, 1884.

The President, Sir ANDREW CLARK, Bart., M.D., LL.D., in the chair.

CASES OF ENTERIC FEVER ASSOCIATED WITH RHEUMATISM.

Dr. FINLAY read notes of five cases, the first of which may be taken as a type of the whole. The patient was a man, æt. 24, a porter by occupation, admitted under his care into the Middlesex Hospital for acute rheumatism on October 1st, 1883. There was a strong family history of rheumatism, and the man himself had had one severe and several slight previous attacks. For a week before admission he had complained of pain, redness and swelling in the ankles, knees, and hips, the ankles being still affected. On admission, his pulse was then 88; temp. 101.4 deg.; tongue slightly coated, and there was a systolic murmur audible over the præcordia. The evening temperature on the day of admission was 103.4 deg. Treatment consisted of salicylate of soda in 15-grain doses, with cotton-wool to the painful joints, under which he rapidly improved. His temperature became normal on October 5th, when he was also free from pain; and he appeared quite convalescent and was allowed to get up on the 13th. He continued to improve till the 19th, when he complained of stiffness in the back, and headache, and his evening temperature was found to be 102.6 deg. Next evening it was 104.2 deg., and from this time onwards the case presented the usual features of one of enteric fever. Rose-coloured spots were observed on the 25th and following days; diarrhoea set in on the 28th; and on the 29th perforation took place; and he died on the 31st. At the post-mortem there was found general peritonitis, the result of a perforation through the lower part of the ileum. Two principal ulcers were found in the small intestine, the one that had perforated, free from slough and with undermined edges; the other, with clean granulating base, to which the edges were adherent, clearly of more remote formation than the former. In order to establish the diagnosis of rheumatism attention was drawn to the redness, swelling, and pain in the joints, the sour sweating, the endocardial murmur, and the history of previous attacks. As to the enteric fever, it appeared probable that it and the rheumatic attacks were co-existent on the man's admission to the hospital, the former being so slight as to be completely overshadowed by the rheumatic manifestations. The fatal attack was therefore a relapse; and this was attested by the different ages of the ulcers in the ileum and by the course of the temperature. Of the four other cases, one, which was fatal, presented very similar features, the fatal result here being also due to perforation of the bowel, which occurred during a relapse. The remaining three presented no special features except the fact of enteric fever following upon an attack of rheumatism. Notwithstanding the fact that no mention was made, even in recent writings, of the occasional association of these two diseases, such association did not seem to be very infrequent. In connection with this view, it was a point of some interest that of seven patients in whom enteric fever became developed in the wards of the Middlesex Hospital over a series of years, five were admitted for rheumatism. Such cases as those recorded suggested the inquiry whether there existed a more than casual connection between rheumatism and enteric fever—an attack of one predisposing to an attack of the other. As regarded the fatal cases, the question arose whether the allowance of solid food after the rheumatic attack passed off was in any degree responsible for the death by perforation. Two practical points seemed to be deducible

from such cases: First, that as solid food might increase the danger of perforation in enteric fever, cases of rheumatism occurring in the course of an epidemic of enteric fever deserved a more than usually narrow scrutiny lest they should turn out to be something more than rheumatism merely; and, second, that if any close connection between the two diseases, such as that hinted at, should be found to exist, rheumatic cases should not be placed in close proximity to cases of enteric fever. Although the facts were insufficient to prove a predisposition, they at least suggested a case for further inquiry.

THE PRESIDENT asked if the two fevers co-existed in these cases, or were sequential to one another.

Dr. FINLAY replied that in one they were concurrent, in the others sequential.

Dr. DOUGLAS POWELL remarked that the cases were both important and interesting, and that he had been about to make the same inquiry as the President concerning the co-existence of the fevers. He had seen three cases bearing on the subject in hand. (1) That of a lady seen on the fifteenth day of illness, and supposed to be suffering from acute rheumatism. She was forty years old, and had previously had attacks of rheumatism. The temperature was 103° - 104° , tongue furred, abdomen tumid, pulse rapid and feeble, and generally she exhibited the symptoms of the prodromal stage of typhoid fever. The temperature subsequently subsided, but rose again slightly on the thirtieth day of illness, on the forty-second day hæmorrhage occurred from the bowels, which had previously been loose; but the temperature had fallen on the fifty-second day, on the fifty-fourth day convalescence was established; a relapse, however, took place, but finally, recovery was complete. (2) Was that of a lady seen in consultation with Dr. Ralfe, in July, 1883, and who had been exposed to sewer gas in a house where typhoid fever had previously been present. This occurred on June 20th, on July 7th there was effusion into both knees; on the 13th temperature was 102° ·5, and there was slight albuminuria; on the 15th diarrhoea, with slightly bloody motions, no sweating, patient much depressed, and exhibiting decided typhoid symptoms. Death took place on July 21, and in the opinion of Sir William Jenner, who had been called to see it, the case was one of genuine enteric fever. (3) The patient, in this case, was admitted to Middlesex Hospital on February 24, this date being the fourteenth day of an attack, said to be rheumatic fever. On admission, however, typhoid symptoms were present. The following day a temperature of 105° was registered, and loose light coloured motions were passed. Thenceforward the temperature steadily fell, fluctuating, however, for some time between 101° and 104° , and convalescence was so far established, that the patient was on the point of going away to the country at the time of speaking. Dr. Powell observed that in these cases the symptoms of two fevers blended together, and that he considered the rheumatic symptoms were developed during the prodromal stage of typhoid. The phenomena were so striking that it could hardly be conceived they would have escaped previous observation if existent, and it would thus seem to be that a new manifestation of disease had been witnessed in this connection.

Dr. DE HAVILLAND HALL said he saw a similar case about eighteen months ago. It was that of a girl with marked presystolic murmur, there was later, a diarrhoea, with typhoid stools, and very evident symptoms of enteric fever, which diagnosis of the disease the further history confirmed. Such cases differed from those in which rheumatic fever and scarlatina were associated, in that in the former class the enteric symptoms were sequential to the rheumatic.

Dr. B. O'CONNOR said that cases of typhoid, which in their early stages presented rheumatic symptoms were common, and were of usual occurrence in sanitary houses.

Dr. HADDEN instanced a case at St. Thomas's Hospital, in which tonsillitis was followed by an attack of acute rheumatism.

Dr. B. ROTH considered that the question to be answered was whether typhoid was induced by the rheumatism?

Sir ANDREW CLARK said he believed the prodromal stage of typhoid fever might last for six weeks, and it was desirable to have an accurate idea, both of its duration and character. During this stage many manifestations of different kinds might be observed. As to the concurrence of the two diseases, he had seen many cases of rheumatism following typhoid fever; and he agreed with Dr. Powell that the facts under

discussion deserved to rank among new complications of disease.

Dr. FINLAY found it difficult to accept the prodromal theory because of the complete break in some cases between the two diseases; and unless the prodromal stage might occupy an indefinite period, no explanation of this kind would suffice. In all but one of his own cases enteric was secondary to rheumatism.

Mr. N. DAVIES-COLLEY on a

CASE OF DISLOCATION BACKWARDS OF THE FIRST LUMBAR VERTEBRA WHICH WAS SUCCESSFULLY REDUCED UNDER ETHER.

A shipwright, æt. 55, was stooping at his work when a mass of iron, weighing 7 cwt., fell upon the small of his back. He was at once admitted into Guy's Hospital. He was collapsed, but quite sensible. The spine of the first lumbar was $\frac{3}{4}$ to 1 inch behind that of the last dorsal vertebra. The adjacent spines were even and formed a continuous series, those above at a level considerably anterior to those below. There was no motility nor crepitus to be detected upon gentle manipulation. He could move his legs, but the right somewhat less than the left. There was impairment of sensation on the outer side of the right leg, and complete loss upon the dorsum of the right foot. Soon after admission, extension was applied under ether. Mr. Davies-Colley kept his hand upon the prominence while three assistants made traction upon the legs. The projection was thus gradually reduced without any jerk; at the same time some crepitus and motility could be felt in the last dorsal spine. A plaster-of-paris jacket, similar to the laminated form recommended by Mr. Furneaux Jordan was applied in the horizontal position, while traction was still being made upon his legs. When he recovered consciousness he was quite comfortable. A more careful examination, two days later, showed that the right musculo-cutaneous nerve was completely paralysed, and there was some loss of sensation between the first and second toes, where they are supplied by the anterior tibial nerve. For ten days he was unable to micturate, and some small bedsores formed over the sacrum, although, within two days of the accident he could turn over in bed and lie upon his side. On the thirty-fourth day after the accident the splint was removed. The line of the spine was then quite even. There was no deformity, and little, if any, tenderness. In less than two months after the accident he was able to walk, but he was still unable to evert his right foot. With the help of Faradisation he gradually recovered power and sensation, and when he was last seen in October, no difference could be detected between the movements of the two legs, and the only abnormality in sensation was a slight numbness in the middle third of the outer side of the right leg.

Mr. BRYANT was of opinion that in the form of fracture described in the paper the value of extension was very imperfectly recognised. Last year a man was admitted at Guy's one hour after meeting with an accident in which he was struck in the nape of the neck by a sack of wheat. Paralysis below the nipple line was fairly complete; and there was a degree of priapism; no loss of sensation, and pain was experienced in the right side of the body. At the third dorsal spine a marked projection could be made out; there was considerable effusion, also, and a fracture of the sternum had been sustained. The diagnosis was fracture and displacement of the third dorsal vertebra. Chloroform was administered and extension applied, when, with a distinct click, the deformity was removed, while on recovering consciousness the patient declared himself free from pain. Next day improvement of the symptoms was present, but anaesthesia of the body surface had come on; and subsequently the patient died from broncho-pneumonia. Post-mortem examination confirmed the diagnosis of the injury, and proved the justifiability of employing extension in such cases. Had the patient been younger, a more favourable result would doubtless have been recorded.

Mr. H. MARSH narrated particulars of a case under Mr. Willett at St. Bartholomew's Hospital some years ago. In this one of the lower dorsal vertebrae was dislocated, and reposition was effected by extension. Death, however, occurred, and post mortem, a fracture was found to divide the body of the bone, proving at the same time the value of the treatment adopted.

Mr. DURHAM congratulated Mr. Colley on the successful result in his case, which he (Mr. Durham) had had an opportunity of seeing when in Guy's Hospital. His own experience of such cases led him to regard them as less hopeless than they

used to be considered. It had early occurred to him that they were likely to be appropriate cases for treatment by plaster-of-paris jackets, but he feared that under such a method there might be danger of injuring the sensory and trophic nerves going to the parts submitted to compression, especially since, in such cases, bed sores or bladder troubles usually led to death. The bladder might be treated easily, but not so bed sores in circumstances of this nature. Under the jacket they were likely to persist unrecognised, so that he would hesitate to apply the apparatus until four or six weeks after the occurrence of the injury. He had recently seen a case of fractured spine recover under Mr. Golding Bird's care. In his opinion treatment should consist at first in support on a water bed, with sand bags on either side; and subsequent application of plaster-of-paris jacket.

Mr. DAVIS COLLEY said he should not employ the jacket when complete loss of sensation below the umbilicus was set up. In his own case sensation was present, and the advantage of the plan of treatment proposed was found in the fact that while bed sores were present over projections uncovered by the jacket, none were produced where the latter enveloped the body.

Mr. ARTHUR E. DURHAM on a

CASE OF SO-CALLED FRONTAL OR SUPRA-ORBITAL NEURALGIA FOLLOWING INJURY, SUCCESSFULLY TREATED BY TREPHINING AFTER FAILURE OF OTHER METHODS OF TREATMENT.

The patient, a man, *æt.* 33, was admitted into Guy's Hospital in October, 1882. A year previously he had been knocked down and kicked on the forehead by a horse. An external wound was produced, extending from about an inch and a-quarter to two inches or rather more above the left external angular process. The wound soon healed. Two or three months afterwards he was thrown out of a cart, and fell upon his head. He walked home a distance of four miles. Soon after getting into bed he began to suffer from intense pain, extending from about the seat of the cicatrix of the old wound towards the top of his head. This pain remained more or less persistent, distracting exacerbations occurring from time to time. His condition became most pitiable; he was altogether incapacitated from attending to his business, and his general health began to suffer. He tried in succession an immense number of medicines and external applications, but without benefit. On the 23rd October Mr. Durham excised about half-an-inch of the external branch of the supra-orbital nerve, and forcibly pulled both the proximal and distal portions. It seemed that the pain occupied the area supplied by this nerve. No relief followed this operation. On the 17th November Mr. Durham again operated, and dissected out and excised portions of other branches of the supra-orbital nerve, and some plexiform filaments of communication between these nerves and the auriculo temporal. The pain remained as severe as ever, though the area over which it spread was more limited. The patient was now sure that the pain started from a spot in the bone very nearly beneath the cicatrix of the original wound. He was ready and anxious to submit to any operation, even at the risk of his life, to be relieved from his agony. Under these circumstances, Mr. Durham trephined the frontal bone at the spot indicated. The portion of bone removed was about an inch in diameter. From the time of this operation to the present he had been entirely free from his old pain. The portion of bone removed was apparently healthy in every respect. It was not obviously thickened, nor indurated. It showed no signs of fracture, nor were there indications of suppuration old or recent beneath it. On subsequent examination, a small depression was found on the internal surface, close to the margin, but this was believed to be only one of those little pits or depressions commonly met with on the internal surface of the adult skull. It was possible, however, that there might have been some small papillary or other outgrowth from the dura mater, involving some highly sensitive nerve filaments, and hence the pain. But there was no evidence of this to be obtained. There was a little bleeding from the dura mater, which was easily arrested, and the dura mater then presented a normal, healthy appearance. The wound was dressed, and subsequently treated in the ordinary way. No bad symptoms of any kind supervened. The wound filled up by granulation, and the patient steadily recovered. He left the hospital on the 28th Feb., speedily regained health and strength, and was soon able to resume his ordinary avocations. He was last heard of two

days ago (some fifteen months after the operation), and reported himself as quite well and entirely free from all pain. Though the result of the treatment was so successful, Mr. Durham considered it would have been more satisfactory if the cause of the pain could have been discovered, and definitely ascertained. He thought the case was allied to those well-recognised cases classed together under the designation *osteitis neuralgica*. Although in almost all of such cases it was one or other of the long bones affected, and, as a rule, there was marked thickening and induration of the bone, Mr. Durham further thought that his case might be taken as illustrative of the comparative immunity with which the skull might be trephined in cases in which there was a prospect of benefit resulting from such operation—an operation the dangers of which he believed to be very much over-estimated. He had brought the case forward, not with the idea of advocating for one moment the adoption of any such severe measures in ordinary cases of supra-orbital neuralgia, but rather to illustrate the good that might be effected by well-directed surgical interference in certain cases in which medicines internally and applications externally proved altogether useless.

Mr. WALSHAM said that Mr. Langton had trephined in the case of a carman, *æt.* 22, who suffered severe pain following on an old compound fracture. The operation completely removed the pain. Mr. Walsham had collected records of seven hundred cases of trephining, thirty of which were for the relief of neuralgic pain. Half of them were due to infliction of blows; in the others no cause could be assigned. Results were good; death occurred in five instances; and in two-thirds pain did not return. In the five fatal cases other causes than the operation were to blame for the result. Two cases at St. Bartholomew's Hospital illustrated the difficulty experienced in deciding where the trephine should be applied. In one a small exostosis existed, but it was impossible to say whether this or hysteria could be assigned as cause of pain. In the other a blow had been received on the head, and constant occipital pain was present in it, but in no point so definitely as to determine exactly where trephining ought to be performed.

Mr. DURHAM briefly replied.

ACADEMY OF MEDICINE IN IRELAND.

PATHOLOGICAL SECTION.

A MEETING of the Pathological Section was held on Friday evening, February 29, at the College of Surgeons, Dr. CORLEY, Sectional President, in the Chair.

STRICTURE OF RECTUM.

Mr. MCARDLE exhibited a specimen of stricture of the rectum taken from a patient, who died of peritonitis. The stricture was situated at the junction of the middle and lower third of the bowel, and extended downwards to within two inches of the verge of the anus. The intestine below the seat of disease was smooth and dilated. The stricture with difficulty admitted a No. 9 gum-elastic catheter. The upper opening of the strictured part was surrounded by a large ulcer, which perforated the anterior wall of bowel, which at this point was attached by bands of adhesion to the recto-vesical fold of the peritoneum. He believed that traction by this fold on the margin of the very sensitive ulcer produced the severe pain, which in this case occurred before micturition. The stricture was of the malignant variety.

CONNECTION OF ACUTE DIABETES WITH PANCREATIC DISEASE.

Dr. DUFFEY reported a case of diabetes occurring in a farm labourer, 24 years of age, the duration of which from the first recognition of the characteristic symptoms of the disease until his death was two months. There was a sudden onset of abdominal pain, vomiting and diarrhoea a week before death, the mode of which was, as is usual in acute cases, by coma. Nothing remarkable was observed by the naked eye at the post-mortem examination with the exception of the condition of the pancreas. This gland was hypertrophied, and felt extremely indurated, the hardness being due (as the microscopic sections made by Mr. Abraham showed) to carcinomatous infiltration. It was well known and remarkable that a diseased state of the pancreas should so frequently be found associated with diabetes. He quoted several authorities showing that the frequency of such association was 50 per cent., and that in

most of these cases the disease was rapid, and the termination quickly fatal. The results following experimental obliteration of the pancreatic canal in animals was referred to as throwing some light on the peculiar type of the disease. In these cases of diabetes the pancreas seemed to be more frequently atrophied than hypertrophied. This difference in the condition of the gland in different cases of the same disease might be explained by the duration of the case. In very acute forms of the disease there might not be sufficient time before the death for the atrophic change which generally followed the primary inflammatory enlargement of the gland to occur. The author admitted that there were on the other hand numerous records to show that the pancreas may be diseased apart from any glycosuria. At the same time there was evidence to show a connection between certain morbid lesions of the pancreas and diabetes constituting a particular type of that disease. He discussed the views of Klebs and Lauder Brunton in explanation of the assumed co-existence, and referred briefly to the subject of carcinoma of the pancreas. It was not unreasonable to infer that there is a peculiar form of diabetes which runs an acute course, is most common in young subjects, and in which the initial symptoms come on with marked brusqueness; that the fatal coma characteristic of these cases is ushered in by suddenly occurring abdominal symptoms and that in this form of the disease especially are morbid lesions of the pancreas.

INTESTINAL CONCRETIONS.

Dr. CHARLES B. BALL showed a number of calculi from the intestines of a horse. Two of these were fine examples of the oat-hair concretion. One was rough and tuberculated on the surface, and a section was found to be composed of concentric layers of vegetable hairs, with a considerable quantity of phosphatic matter and portions of the husk of the oat. The second was smooth and uniform, both in surface and in section, and was composed almost entirely of oat-hairs closely felted together. Microscopic slides of both these calculi, with the hair of the oat seed for comparison, were exhibited. The author also brought forward a collection of fourteen concretions, composed chiefly of ammonia magnesium phosphate, the nuclei of which were very various, including iron nails, small stones, vegetable matter, a piece of leather, &c. Some were much faceted, and illustrated distinctly the two ways in which this appearance is produced. The one which was of prismatic shape and section showed that the concentric layers were continuous all round, but it was evident that the layers were much thicker in the direction of least resistance, namely, at the angles of section, while they were thinned off at the portions corresponding with the facets. In others it was evident that the faceting was due to the rubbing of one stone against others, as the layers were cut through at the facets. One of the concretions was of a peculiar shape, being concavo-convex, and sections showed that this was evidently a portion of a calculus which had undergone spontaneous fracture within the animal. Additional evidence of this was to be found in the extreme brittleness of its structure. Microscopic sections of these calculi were exhibited, which showed well the tubular structures found abundantly in intestinal, as well as in urinary concretions, and supposed to be coniferæ. Dr. Ball showed several beautiful examples of argagropiles and bezoars from the museums of Trinity College and the Royal College of Surgeons.

On the motion of Dr. Bennett, seconded by Mr. Stokes, leave was given to Mr. Valentine Ball, who was not a member, to address the Section.

Mr. BALL said he had, at his brother's request, brought the specimen, the first impression having been that it might be a fossil calculus belonging to some extinct animal; but he had obtained information which showed that, within the last year, a number of rounded masses of triassic phosphate had been introduced into the country for the manufacture of manure. Six months ago he received two specimens, and he had the sections made which were now exhibited. He noted the absence of concentric rings, but it occurred to him that they might have been obliterated by crystallisation. Having exhibited the specimens to the Geological Society, he learned that masses of the kind were abundant in Podolia and Bessarabia, but unaccompanied by any fossil mammalian bones. They resembled specimens of calculi in the museum of the College of Surgeons, and he had heard that twelve or thirteen years ago similar specimens were described in the "Transactions of the Geological Society of Vienna" as coming from

Silurian rocks, thus excluding the hypothesis of any connection with the mammalia. They might have been derived from original spherical masses of carbonate of lime, and some of the analyses showed that they contained carbonate of lime. They might represent sponges or spherical masses of coral in which the carbonate of lime had been replaced by triassic phosphates; or they might be spherical conglomerations of iron pyrites. When obtained from the mother the rock specimens were rough, but when they had been rolled in rivers they presented a polished surface.

Dr. MOORE said he had some years ago got possession of the remains of a crocodile eleven feet long, and on examination he found pendant from the exterior of the intestines and encapsuled, stones and other refuse which the reptile had evidently swallowed, and which instead of having been passed out in the ordinary way had been extruded through the lining membrane of the bowel, lying between it and the peritoneum apparently without having caused any irritation.

Dr. FRASER remarked that, several years ago, he attended an old woman, a cook, for a tumour in the cæcum the size of his two hands. From time to time she passed what he thought were the joints of a tapeworm, but on examination they were found to be portions of the ligamentum mûchæ of a calf which had collected forming the tumour, and which was got rid of by doses of castor oil. Some years afterwards he attended another female for a tumour in the same region, and purgatives produced a ball about the size of a walnut. She had been in the habit of eating her own hair, and the ball was proved to consist of rolled-up hair. Afterwards he attended a young man employed in a shop, who had been in the habit every time he tied a parcel of eating a bit of twine. He got the tumour away, and it proved to consist of pieces of twine. Concretions found in cattle were most common in this country. These concretions were the result of the animal licking its own skin. Calves did so more than cows, and unless they vomited the concretion so formed, they grew emaciated and died. In the old National History Society Archbishop Whateley read a paper on the licking of bones by cows, in which he stated that perfectly healthy cows did not lick bones. In the old days when Scotchmen ate a great deal of strabout the formation of intestinal concretions made of the oatmeal husk was much more common than now. He had seen numerous specimens of these concretions in the old Hunterian Museum. The nearest approach he had ever seen in this country to the bezoar stone of the East was taken from the body of a lunatic who had been employed French polishing, and imbibed habitually methylated spirits containing shellac which formed a concretion in the stomach. Straw was sometimes swallowed by lunatics and formed concretions. As to the curious phosphatic masses mentioned by Mr. Ball, he had himself obtained specimens from a large manure manufacturer, and came to the conclusion that they were metamorphosed tissue of some kind or other, but the curious thing about them was that they were phosphatic.

Dr. BENNETT observed that the essential difference between the concretions which were of animal origin and those which arose under geological influences, and which they had good authority for believing to be the result of chemical or mineralogical action was that the latter did not present the concentric arrangements that were observed in the former.

Dr. BENSON mentioned that he saw in the Whitworth Hospital a ball, the size of a pill-box, which was taken from the stomach of a girl, ten years old, and which proved to consist of the pickings of blankets she had eaten.

FATAL MENINGITIS AFTER ENUCLEATION.

Mr. ARTHUR BENSON showed the brain and read the notes of a case of meningitis which had occurred in a girl, æt. 17, after enucleation of a shrunken eyeball, the result of second purulent inflammation excited in an old blind staphylococcus eye. Headache, vomiting, &c., began on the day after the operation. On the fourth day a bright erysipelato-like blush occurred on the eyelids, nose, and both cheeks, which disappeared in thirty-six hours. There was no discharge from the socket of the eye which had been removed, but on the day that the red blush was first seen there was slight secondary hæmorrhage from the wound. The case presented some points of difficulty about the diagnosis. Many of the symptoms pointed to suppressed scarlatina, others simulated erysipelas, while meningitis was also strongly indicated. Death by coma occurred on the eighth day, and the autopsy confirmed the diagnosis of meningitis, the whole surface of the pia mater everywhere being covered with lymph and pus. A résumé of nine other

cases, all that the author could find record of, was given, and of the nine only two were known to have occurred after enucleation of the eyeballs in a state of purulent panophthalmitis, while four were known not to have been purulent, and in three the condition of the eye was not stated. It was thus shown that purulent disease of the eye at the time of enucleation was by no means a necessary condition for the production of consequent purulent meningitis. It was suggested that an atrophied and shrunken nerve with a loose sheath offered favourable conditions for the conduct of infection from the socket of the meninges of the brain, and that condition was present in four of the eight cases.

Mr. P. S. ABRAHAM, who had made sections of the optic nerve and surrounding tissue, taken at a distance of about 1 c.m. from the foramen, stated the result. The nerve was profoundly altered. No distinct fibres could be made out, but the pericranium and the interfibrillar prolongations were greatly hypertrophied. The spaces which the latter enclose were occupied by a continuous granular material freely interspersed with nuclei. The connective tissue of the framework was itself filled with proliferating cells, which were massed together in some places. The sheath of the nerve was thickened, and towards the outer boundary the fibrous bundles were separated by spaces containing numerous small cells and nuclei, and further out still these were sufficiently abundant to be looked upon as purulent deposits. Some of the sections were treated with methyl blue, and by this means he thought he could detect micro-organisms among the pus cells and between the fibrous bundles. A complete examination, however, had not yet been made. Sections of the kidney showed marked hyperæmia, the vessels being largely distended with blood and bulged in places. No extravasations had been seen. The urinary tubules were quite occluded by the swollen and granular epithelial cells, which had lost their marginal boundary or contour. The materia was studded with collections of inflammatory cell-growth.

The PRESIDENT asked, was erysipelas present in the hospital at the time.

Dr. BENNETT said the evidence of erysipelas in the case depended largely on the appearance of the patient's face, which prevailed one evening and disappeared next morning without any desquamation following. His opinion was that the affection was an erythema, but not an erysipelatous erythema. The rash on the face was due probably to nerve disturbance. He did not think there was any other case of erysipelas in the hospital.

Dr. STONEY agreed that there was no erysipelas in the case; nor had he thought so at first, until the enormous red swelling and blood appeared after the occurrence of the blood-clot. After the rash disappeared he came to the conclusion that the case was one of meningitis without erysipelas. Dr. Stoney, of Abbeyleix, had stated there were some cases of scarlatina in a building next door to where this case had been, and that made him think this case was the commencement of scarlatina; but that hypothesis was disproved. When the girl came to the hospital she was dull and stupid, and she put her hand to her head complaining of headache, so that it was possible there might have been cerebral affection independent of the operation altogether. The case was remarkable, there being so few instances of affection of the brain occurring after enucleation of the eye. The operation was a perfectly safe one. He never saw but one case of trouble after it.

Dr. J. W. MOORE said he saw the patient two days after the operation, and he was struck by the strange combination of symptoms presented, an exceedingly high temperature and a pulse of only 80. He at once suggested meningeal trouble, a view borne out by repeated vomiting and violent cardiac action. The throat was œdematous. It was livid rather than red, and was covered with an exudation, and very like the throat of a person suffering from malignant scarlet fever. The tongue also resembled that of a scarlatina patient; but on the other hand, the slowness of the pulse was a symptom opposed to the supposition of scarlatina. Again, the respiration was such as to prove there was nothing whatever wrong with the lungs. On all these symptoms he expressed the opinion that the case was probably one of meningitis, and that any moment the rate of the pulse might double. Subsequently the pulse rose from 155 to 160. He could understand the probability of the girl from the time she came to town suffering from the initial

stage of meningitis. There was a good deal of erysipelas in Dublin at present, but when he saw the girl she had no trace of erysipelatous swelling, and he thought the meningeal symptoms sufficient to exclude the idea of erysipelas.

DIABETES MELLITUS—MICROSCOPIC SECTIONS.

Mr. P. S. ABRAHAM gave a demonstration of sections from two cases of diabetes mellitus.

Special Articles.

MR. WATSON CHEYNE ON BACTERIA.

A VERY distinguished company assembled at the Parkes Museum on Thursday evening, March 27th, to witness Mr. Watson Cheyne's demonstration of pathogenic micro-organisms. The chair was taken by Sir Joseph Lister, Bart. After stating that the great group commonly called Bacteria might most conveniently be sub-divided into four classes—1. Micro-cocci (round bodies); 2. Bacteria (small oval or rod-shaped bodies); 3. Bacilli (large rod-shaped bodies); and 4. Spirochætic and Spirilla (rods spirally twisted); and dwelling on the great variety as well as importance of the various parts played by this great group in the economy of nature, Mr. Watson Cheyne demonstrated numerous micro-photographs taken by Dr. Robert Koch as well as some drawings, by means of a lime-light apparatus. He observed that great difference existed among the various bacteria in their behaviour towards the human body, some could be injected without causing any injury, others could not grow in the living body, but could develop in dead portions of tissue, and the secretions of wounds, giving rise to poisonous products. The true pathogenic organisms were able to attack the living body and multiply in it; they included the organisms which found entrance through some wound giving rise to the traumatic infective diseases, and others which could obtain entrance without observable wound. Further certain organisms such as the *b. anthracis* were capable of growing outside the body in dead organic substance, while others such as the *b. tuberculosis* were apparently only capable of developing in the living organism or under artificial conditions which reproduced, to some degree, those existing in the tissues of warm-blooded animals, though capable of long retaining their vitality in the dry state. With regard to the traumatic infective diseases he thought that the most absolute proof had been furnished, that the bacteria found in them, and nothing else, were the causes of these diseases, to establish such a proposition it was necessary that an organism of a definite form and with definite characteristics should always be found in the blood or in the affected part. The blood or the affected part when inoculated into another animal of the same species produced the same disease. When the blood or the affected part was inoculated on a suitable soil outside the body the micro-organisms grew and must be indefinitely propagated on similar soil. When in this manner the organisms had been separated from the remains of the materials in which they were embedded, their inoculation in an animal must produce again the same disease, the same organisms being found in the diseased parts. These conditions had now been fulfilled with regard to anthrax, septicæmia of the mouse, erysipelas, tuberculosis, glanders, and acute pneumonia. With regard to typhoid fever, relapsing fever, cholera, and ague, the evidence was very strong, but not conclusive. Mr. Watson Cheyne concluded by dwelling on the importance of surrounding circumstances, chiefly summed up in the phrase un-hygienic conditions, as concomitant causes of disease

by preparing the body for the attacks of these micro-organisms.

The Chairman, Sir Joseph Lister, dwelt upon the important fact that the organisms which produced particular diseases were only able to develop under very special conditions, instancing the bacillus, which caused septicæmia in the house-mouse, but which was unable to produce any deleterious effect on the field-mouse. He thought this fact, which showed that the very slight difference in the blood of these two animals was sufficient to alter the conditions favourable to the development of the bacteria, might prove of very great interest, as it was possible to conceive that by the administration of some medicines sufficient alteration might be produced in the blood of the human system to kill off or to prevent the development of any special bacteria on the first appearance of the symptoms of the disease in the patient. Sir Joseph Lister concluded by referring at some length on the importance of Pasteur's researches on modified virus. Prof. Humphry paid an eloquent tribute to the great work which Sir Joseph Lister had already achieved, and looked forward with a large hope to the future of Medicine.

France.

[FROM OUR SPECIAL CORRESPONDENT.]

FRENCH OPHTHALMOLOGICAL SOCIETY.—This Society held its first meeting for the session 1884 on the 8th January, and three following days, under the presidency of M. Javal. Professor Panas congratulated the Society on its success during the past year, its numbers having now increased to 104 members. M. Masselon read a paper on "Vitreous Inflammation of the Retina and Papilla," caused by the penetration into these organs of warty productions, which are sometimes developed on the vitreous lamina of the choroid, more especially in that of old people. Next followed an important discussion on Jequirity, which was brought forward by M. Coppey (Brussels). The results obtained by the use of this medicine are the following:—Of 164 patients, 140 were attacked with complicated granulations of the inveterate pannus, and were treated by lotions of five to ten per cent., once or twice daily. In one and a-half or two months the most obstinate warts were cured. In the same way jequirity is much superior to blennorrhagic inoculation; this is a remedy which can never be used when only one eye is affected without danger to the other. In any case, the disease has never been aggravated by it. M. Menacho treated 300 cases of jequiritic ophthalmia in M. Wecker's *clinique*, and he came to the conclusion that this substance may be used with great advantage in the torpid forms of ulcers of the cornea, in facietted cicers, and especially of interstitial keratitis; in scrofulous pannus, and the symptoms following parenchymatose keratitis, infiltration, and sclerosis. M. Vallez, of Tournay, who practises in a country where granulations of the conjunctiva are very frequent, stated that he has effected some cures which might be considered almost marvellous. There were fifteen patients, seven of which were admitted to a hospital for the blind as incurables. He only failed in six cases, and none of the accidents were of a serious nature; but, contrary to M. Coppey, he noticed the propagation of the jequiritic ophthalmia from one eye to the other. M. Abadie considers that jequirity may be used in inveterate conjunctivitis. He has done so successfully himself, but, in cases of slight conjunctivitis, he prefers sulphate of copper or salts of lead. Perhaps the parasites of jequirity exercise antagonistic pro-

perties to those of the microbe of granulated ophthalmia, but one may modify the conditions of the system in which the disease is developed, and therefore requires a general therapeutic treatment as well as the local remedy. At M. Nicot's request he described the different actions of this remedy at three different periods—1st. In the beginning or acute stage jequirity is more injurious than useful; in the 2nd or ulcerous period it sometimes produces beneficial results, but this is exceptional; while in the 3rd or fungus condition it is of very great service. M. Dor, of Lyons, and M. Galezowski spoke against the new medicine, while MM. Terson, Vachey, and others were greatly in favour of it. M. Parinaud mentioned that perhaps the difference between the results of M. Coppey and M. Gaget was caused by the fact that one operated on adults, the other on children, while MM. Grand and Chimbret attributed it to geographical relations. It was also stated that jequirity is useful in cornean alterations, but is quite useless in lesions of the conjunctiva. The discussion was here adjourned to the next meeting. Further communications, which we regret we are not able to analyse, were read. They were M. Motais on "The Muscles of the Eye and the Capsule of Tenon in Man and Animals." M. Dehenne on "A Case of Suppuration following the Extraction of Cataract in a Man suffering from Affection of the Liver." M. Stoeber on "The Theory of Central Optical Systems." "On a New Mode of Incision of the Cornea," by M. Pamard. "On a Case of Absolute Glaucoma of the Left, with Iritis of the Right Eye, cured by Iridectomy of the Right Eye," by M. Coursserant; and finally, "On the Absorption of Actinic Radiations by Crystalline."

THE deaths registered last week in the principal large towns of the United Kingdom corresponded to an annual rate of 20·8 per 1,000 of their aggregate population. The death-rates in the several towns were:—Derby 12; Brighton 13; Bristol 14; Bradford 15; Huddersfield, Birkenhead 17; Plymouth, Leicester 18; Sunderland, Bolton, Sheffield 19; Wolverhampton, Nottingham, London, Birmingham 20; Salford, Leeds, Cardiff, Hull, Edinburgh 21; Liverpool, Portsmouth 22; Norwich 23; Newcastle-on-Tyne 24; Blackburn 25; Dublin, Glasgow, Manchester, Oldham, Preston 27; Halifax 30.

THE highest annual death-rates from diseases of the zymotic class in the large towns last week were—From measles, 5·1 both in Portsmouth and Oldham, and 2·2 in Birmingham; from whooping-cough, 1·9 in Bolton, 1·6 in Salford, and 1·5 in London; from scarlet fever, 2·8 in Sheffield, and 1·6 in Leeds; and from "fever," 1·1 in Birkenhead. The 30 deaths from diphtheria included 11 in London, 6 in Glasgow, 4 in Edinburgh, and 2 in Salford. Small-pox caused 11 deaths in London, 2 in Liverpool, 2 in Sunderland, 1 in Birmingham, and 1 in Newcastle-upon-Tyne.

IN reply to a question by Mr. Corbet in the House of Commons, on Friday last, as to the existence of British subjects in insane asylums abroad, the Home Secretary replied that the Lunacy Commissioners had informed him that there were no facts which could be got to enable him to answer the question of the hon. member.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, APRIL 9, 1884.

THE FUTURE OF THE ROYAL COLLEGE OF SURGEONS OF ENGLAND.—I.

At the present time the affairs of the English Royal College of Surgeons are fraught with a degree of interest and importance which, as far as the general profession at least is concerned, they have never before possessed; for in place of being henceforth what it has hitherto been in the past, a close corporation, the College is destined to become a living centre of universal concern to all the numerous body of practitioners whose professional avocations are carried on beneath the cover of its licence. We say *is* destined to become, because we are convinced that the desire for reform has been most effectually kindled already, and needs only to be constantly and judiciously fanned to result in the gaining of all those advantages and improvements, the justice of which has been practically demonstrated by the unanimous voice of the meeting of Fellows and Members recently held at the College. Under these circumstances it is necessary that every one connected with the institution should be in a position to judge accurately for himself on what grounds, and for what reasons, the changes contemplated by the majority should be carried out; and with the object of affording this information, we purpose in this and two or three subsequent articles to devote attention to the subject in the various aspects it presents.

It may be at once admitted that the resolution of highest importance affirmed at the meeting referred to above, was that proposed by Mr. Forrest, and which provided

for three essential modifications of existing rules—viz. (1) that Fellows and Members shall be invested with some share of the management of the College to which they are attached; (2) that an annual meeting of such Fellows and Members shall be held for the purpose of receiving an account of their stewardship from the Council of the College; and (3) that the first officer of the College shall be elected at such meeting by a majority of Fellows voting at it.

Those who were present at the meeting on March 24th could not fail to have been at once impressed and amused by the anxiety exhibited on the part of the chairman to declare that nothing that might be done on that occasion could be supposed to have any binding effect on the Council, the members of which, he affirmed, would regard any resolution transmitted to them from the meeting as merely *recommendatory* in character, and as suggestions for their consideration. This excessive precaution was so far a satisfactory sign that the ruling powers had already become uneasily conscious of the insecurity of their position; but it ought not in any way to influence the pre-determination of reformers to carry out to the uttermost the programme of salutary reforms they have agreed upon. For a time, even, we may be called upon to witness the spectacle of rejection, counter-rejection, and insistence rendered familiar to every student of political history; but, as in national struggles against oligarchical combinations, the cause of right is always ultimately successful, so in this instance we may hopefully anticipate the issue, whatever the immediate attitude of present authority may chance to be towards the popular cry for reform. It would possibly be too much to expect an unconditional surrender by the Council of the power it has so long exercised; but none the less concessions must be made, and at a later stage we propose to point out the manner in which unwilling assent to them can be enforced, should such a mode of obtaining them be necessary.

From the first commencement of the agitation for a reformed management of the affairs of the College we have been actively interested in promoting the movement; and, following the conclusion of the meeting in which this agitation culminated, we made it our especial business to ascertain the light in which the individual members of the Council regard the resolutions which were then adopted by unanimous consent of all present. And here at once it has to be confessed that the outlook is anything other than promising, and that it affords ample occasion for indulgence of pessimist views regarding the prospect of troublous times. A few of the Council, constituting a by no means large minority of that body, are prepared to cede into the hands of Fellows and Members a *limited* voice in the administration; but even these, it is to be inferred, incline to stop a long way short of what is contemplated in the resolution by which their opinion has been influenced. On the other hand, however, the major number of their colleagues are utterly opposed to granting any part of the demand which has been formulated; and if we may accept past experiences as an indication of the unbending fixity of purpose that will characterise their action in the future, there is but little to hope for any change of front as far as they are concerned. Perhaps,

however, it would be premature to anticipate too obstinate an opposition from them, for, dwelling as they now do in a paradise of their own creating, and the barriers of which they presumably think to be impregnable, their resolution to resist is likely to fail before the first clear signs of a breach in their defences. And such a means of attack is, as we shall explain later on, most certainly possessed by those whom the obduracy of the Council will by-and-by drive to extremes.

To different minds, moreover, the idea of "limited power" assumes very varying proportions; we have known instances in which it has been assumed that "power" is given to those who are permitted, and required, to carry out the obligations imposed upon them, and in the formulation of which they have had absolutely no voice whatever. Whether this conception of "limited" power is that of the gentlemen alluded to above, we are unable to say definitely; but that they are prepared to accept the full reading of the demand contained in the resolution of Fellows and Members of the College, may forthwith be decided in the negative.

It is necessary, therefore, to proceed at once to a consideration of the question whether any such delegation of authority is likely to react advantageously to the corporation and to those who make up its licentiates. The obvious reply of placeholders is that the position now held by the College is one of pre-eminence, and that, having attained it under existing regulations, no occasion for altering them has arisen. To this it can be returned that the College is what it is by virtue of possessing exceptional advantages in the past; but that it is called on to compete against rivals of increasing power every year, while in the meantime a spirit of dissatisfaction with it is rapidly increasing among those from the number of whom its importance is derived. So long as the possessor of the College licence was content to regard it as a mere instrument for earning bread, and to look upon the College itself as an emporium for the sale of qualifications, so long the principles of barter and exchange were safely trusted to regulate the transactions between licenser and licensee. Of late, however, the mental calibre of the profession as a whole has undergone improvement in comparison with its former dimensions; and with this increase of intellectual range has arisen also a strong desire to utilise every means that exist for advancing professional influence and excellence. The College of Surgeons occupies a prominent position in this list; and it is naturally desired by those who have allied themselves with its fortunes that the force it exerts shall be wielded to the best advantage. They do not consider that this follows from the action of those who now exercise *all* authority; and they, therefore, seek to reinforce the latter by lending them the combined strength of the whole electorate of the College.

At other institutions where archaic rules do not obtain as they do at the College of Surgeons, vast advantages accrue from general participation in the management of concerns of common interest to all. The Universities derive the principal weight they exert from the fact that every senior graduate is by right a voter on every question of general importance. The College of Physicians of London derives its strength mainly from the voice of its

Executive; and so on throughout the list of great intellectual and educational institutions, until we come to the Royal College of Surgeons of England, which is unique among kindred associations as being ruled and governed by a small band of autocratic and irresponsible men, who consider themselves free to ignore the combined opinions of 18,000 persons.

THE GENERAL MEDICAL COUNCIL AND ITS WORK.

A CALM survey of the labours of the General Medical Council during the session just completed reveals nothing, so far as we can discern, to indicate any necessity for the expenditure of time and money occasioned by the calling together of the Council. Except that one or two names have been removed from, and one or two others restored to, the *Register*, there is really nothing to show for the outlay that will be credited to this meeting, and charged against the accounts for the year. And this is felt to be an unsatisfactory condition of things by a small minority of the Council, who recently, as on a former occasion, sought their best to cut short a meeting which was absolutely uselessly and aimlessly extended. The effort was vain, however, for unfortunately the Council includes a considerable percentage of members who seemingly resolve at any cost to protract the meetings to the utmost limits possible. Their capacity for talking, as distinguished from speech-making, is all but limitless, and the ingenuity they display in inventing excuses for discussion would command admiration if applied to a better cause. As a rule, however, good sense of the Council prevails over any continued obstruction of this nature, although last week it seems not to have been applied with customary success. Any way, the Council pursued the undignified course of accepting a proposal to discuss the clauses of the Medical Bill now before Parliament, and thereby destroyed the good effect produced on the profession last year when it refused assent to Mr. Macnamara's proposal, and which this year it has acceded to. The Council might have been content to continue in the belief it expressed twelve months ago, that, viz., that the Government would have invited its opinion on the Bill if it had been deemed at all valuable or desirable. Now, having declared it unsolicited, the Council is placed in the awkward position of a leap-year lover who proposes unasked, and is met with the scornful silence she so richly merits.

The unprecedented bad taste shown in respect to proposed conjoint examining boards at the very time when the attention of the House of Lords was engaged on a scheme for uniting all examinations in one, is the worst exhibition of the kind ever seen, either in the Medical Council or out of it. Unfortunately, too, the spirit of determination to go on with the discussion was too general among members to admit of any preventive measure being applied; and the result has been that several days and some hundred of pounds have been expended in approving a scheme that bears every sign of being a snare, and that depends for execution on Parliamentary accidents. Being the last session it is likely to hold, it may have occurred to members of Council to make it a memorable one. If this is the case they enjoy the

holy satisfaction of knowing they have succeeded beyond hope.

THE FINANCE OF THE GENERAL MEDICAL COUNCIL.

THE accounts presented last week to the Council show the following comparative figures.

The three Branch Councils began and ended the year 1883 as follows:—

	Began 1883 with	Received in 1884.		Cash balance now in hand.
		Registration fees.	Interest income.	
English...	£2,758	£3,790	£868	£3,571
Scotch...	34	1,661	93	264
Irish ...	327	1,256	54	639

In addition to these cash balances, the Branch Councils have invested funds—

English ...	£30,500
Scotch ...	3,200
Irish ...	1,869

It may reasonably be asked, What is to become of this £40,000 when the Medical Bill passes? It is to be handed over to the new Medical Council, to be disposed of at their absolute discretion, subject to the approval of the Privy Council. The new Council may subsidise teaching bodies with it, or establish lectureships, or appropriate the fund to pay fees to itself, or lay it up to accumulate. In fact, there is hardly any conceivable use—or abuse—to which the fund may not be put if the Privy Council permits, and it therefore seems likely that it will be in the same condition as the Irish Church fund, and that every party which wants money will have a pull at it until it is exhausted.

The General Medical Council in the year 1883 paid into the pockets of its own members over £1,500. This sum represents seven days' sitting of the Council, besides 4 meetings of the Executive Committee and 12 of the various Branch Councils. This means that the preparatory arrangements and the business done (if any) by the Council in 1883 cost the profession £216 per day of the meeting for members' fees alone. The central establishment in London, including the work of the English Branch Council and the printing of minutes, cost £1,800 additional, while the Scotch and Irish Branches cost for establishment £256 and £433 respectively.

Thus it appears that a grand total of nearly £12,000 passed through the hands of the Council in this one year, every penny of it contributed by the medical profession.

We do not ask whether the profession considers that in the year it has had value for its money, but, with such a fact before us, we are aghast at the audacity of those who declare the opinion that the medical profession has no business with the Medical Council or its proceedings, and no right to grumble at its inefficiency or to claim a share in its work.

AN appeal has been lodged in the Queen's Bench in the case of *Page v. Harrison*, on the ground that the verdict was against the weight of evidence. It will be remembered that Dr. Page, of Solihull, near Birmingham, sued the defendant Harrison for damages for slander, the jury finding in his favour with £150 damages and costs.

Notes on Current Topics.

A Biological Association.

A VERY important meeting of scientific and amateur biologists was held last week at the rooms of the Royal Society, Professor Huxley presiding. The object of the gathering, which had been summoned at the instance of Professor Ray Lankester, was to found a society for the biological investigation of the British coasts, and it is hoped and intended that it would work in harmony with another association formed lately, under the auspices of H.R.H. the Prince of Wales, for the purpose of prosecuting the practical study of biology. A resolution, moved by the Duke of Argyll, and seconded by Sir Lyon Playfair, M.P., was carried, whereby it was declared "That in the opinion of this meeting there is an urgent want of one or more laboratories on the British coasts, similar to those existing in France, Austria, Italy, and America, where accurate researches may be carried on, leading to the improvement of zoological and botanical science, and to an increase in our knowledge as regards the food, life, conditions, and habits of British food fishes, and mollusks in particular, and the animal and vegetable resources of the sea in general." A provisional council, with Professor Ray Lankester as secretary, and Mr. Frank Crisp as treasurer, was subsequently appointed to carry out the objects of the meeting; and it is estimated that a sum of from £6,000 to £10,000 will be required to put the project to the test of practice.

Fire at a Gaol in Manchester.

WHAT threatened at one time to be a terrible and disastrous fire broke out a few days ago at the prison situated near the Belle Vue Zoological Gardens, in the outskirts of Manchester. The flames arose first in the stores department, no explanation of their origin having yet been found. Thence they spread, and threatened to engulf the whole gaol, including that portion devoted to the purposes of a hospital. The sick prisoners then in the wards were hurriedly removed, and every precaution taken to prevent injury to life or limb. As was to be expected, there was much trouble experienced in keeping the prisoners, of whom about 1,000 were in the place at the time, in subjection; and nothing but the determined attitude of those in charge of them prevented their taking by force the liberty for which they repeatedly clamoured. Under the peculiar circumstances too high praise cannot be given to the admirable courage and discipline exhibited by the whole prison staff in the trying position they suddenly found themselves in; and especially is this the case in respect to the prompt and thoroughly successful measures taken for preserving the safety of the sick and helpless prisoners unable to extricate themselves from the danger menacing them.

THE new Medical Bill passed the third reading in the House of Lords on Thursday last, and is now down as one of the early Government measures for legislation in the House of Commons.

Diphtheria Spread by a Doll.

A CURIOUS case of diphtheria recently occurred in Amsterdam, New York. A child during its illness from that complaint, says the *Sanitary Engineer* of New York, played with a doll, which was afterwards given to a younger child, as it was supposed to have been properly fumigated with sulphur fumes. This child, shortly after being allowed to play with the doll, also fell ill of diphtheria and died. A third child was also attacked after playing with the doll, but recovered. The Board of Health, finding no bad conditions existing in or about the house sufficient to explain the appearance of the disease, traced its appearance in the family after the death of the first child to the doll.

What Next?

DR. PATRICK HERON WATSON is much distressed in mind at the thought that the utterances of himself and his fellow members of the General Medical Council do not always find *verbatim* repetition in the columns of the medical journals. This shortcoming is, to him, a matter of very serious import; so much so, indeed, that he has given notice of an intention to move a resolution to the effect that the Council shall publish its own reports, on the lines of "Hansard." The date for bringing forward this motion, however, is wisely deferred to a "future occasion;" and in this connection we would respectfully suggest to Dr. Watson that the Greek Kalends will be the most suitable opportunity he could select for the purpose. It cannot be denied that the feelings of an orator who is conscious of having made a strong effort, must be considerably irritated by finding his cherished periods ruthlessly reduced to merely representative sentences, in the reports to which he had fondly looked for a reproduction in type of his spoken eloquence. Unfortunately, however, it is a fact, of which Dr. Watson seems still unaware, that the interest taken by the profession in the proceedings of the Council of which he is so prominent a member is so small that it scarcely justifies the devotion of any space thereto in professional journals. When Dr. Watson's two years' Council experience has extended somewhat, he will probably be less anxious to preserve the records of its deliberations; and certainly should his proposition be acceded to, the accumulation of copies of the new publication will seriously embarrass the officers of the Council whose duty it would be to store them; the number sold will be less than that of contributors. But possibly Dr. Watson will demand gratuitous circulation of the official reports among the whole body of registered practitioners. Only so will he be able to secure that the profession shall be supplied with that which the unfeeling journals now (in mercy) withhold, viz., *verbatim* reports of the Council's proceedings. Even then, however, no assurance that anyone would be the wiser could be given; most probably a very few alone would trouble to read their "Hansard," while the great majority would treat the voluminous record in much the same way as they would any other tiresome effusion, and with as little show of respect. Dr. Watson's ideas are altogether so curiously out of place that he will

probably be convinced of its foolishness long before an occasion can arise for him to challenge a vote upon it.

Fees for Sanitary Prosecutions in Ireland.

AT the Bruff Quarter Sessions, held on the 4th inst., before T. Purcell, Esq., Q.C., County Court Judge, the following case was decided:—Dr. Henry Donovan, of Kilfinane, sued the Kilmallock Board of Guardians for £7 7s. for attending on seven occasions as witness in prosecutions under the above Act. The Guardians were represented by counsel instructed by the solicitor for the Board. Mr. O'Shaughnessy, of Charleville, appeared on behalf of Dr. Donovan.

Dr. Donovan, on being sworn, produced the written orders of the Board for his attendance at the Petty Sessions on the several occasions. The defence made by the Guardians was that it was part of the doctor's duty as Medical Officer of Health to assist at those prosecutions. The learned Chairman, in giving his decision, said that the duty of the medical officer of health consisted in inspecting and reporting on nuisances, and that the additional duty of attending as witness under the Act, when not "included in his salary," should be paid for by the guardians. A decree for the full amount with costs was accordingly given.

Vaginal Injections of Sublimate in Puerperry.

CORROSIVE sublimate is rapidly finding its way to the front as a disinfectant. Amongst others, many others we might say, who are now in favour of it is Dr. Kehrer, of Heidelberg. He dissolves 5 grammes in 200 of distilled water, and of this solution uses a small spoonful (10 c.cm.) to a litre of water. This strength appears to us to be unnecessarily great; one grain to a pint is quite strong enough for almost any purpose. The vagina is swabbed out with this before the first exploration by means of a cotton or other mop, and the vagina is also washed out twice daily after removal of the after-birth, until the discharge ceases. It is not surprising that a solution of this strength roughens the hands and mucous membranes, and that urticaria has appeared on the genitals in consequence. In one case mercurial stomatitis came on, but this was in the case of a syphilitic patient who had been treated by mercury. In the discussion that followed the paper most of the speakers reported favourable results from a similar method of treatment.

Sublimate Solutions in Diphtheria.

DR. RUDOLPH CAESTART, of Uruguay, writes to the *Münchener Intellig. Blatt*, March, 1884, in favour of the treatment of diphtheria by local applications of solution of perchloride of mercury, 1 in 10,000, about gram to the pint. The plan he follows is to sprinkle the floor of the patient's room five or six times a day with a 2½ per cent. solution of carbolic acid, and paint the part affected every hour with the sublimate solution, using a fresh brush or feather each time. For the purpose of quietening the patient after such frequent disturbances, he gives chloral in larger or smaller doses. He has had no fatal doses since adopting this plan of treatment.

The Austrian Army Medical Service.

UP to the present time the number of medical men in the Austrian army has been only 852, a total quite insufficient for any campaign, even if it be a short and unimportant one. In the last expedition to Bosnia the doctors, in spite of all their efforts, could not meet even the necessities of the war. The following reform has been proposed by Inspector Hoor, and is likely to be adopted. Until now recruits have been obtained by young medical men being appointed, after six months' extra study, to the different regiments, but a medical college has been lately established where the curriculum of study lasts five years, and the number of pupils is about 300. The staff of medical men actually in the service has also been increased from 852 to 970, and they will be given the rank of combatant officers. They will have absolute control over the hospitals and all sanitary arrangements, and by not changing them too quickly from one garrison to another they will have every opportunity of getting up a general practice. This method of reform is not without its defects, but we are glad to see some effort has been made to improve the service.

Poor-law Superannuation.

A MIDWIFE of Kilmeague Dispensary, Naas Union, has been obliged to resign from rheumatism contracted during her duties of over eleven years. She had two medical certificates, but there was such opposition shown when a superannuation was mentioned, it was believed to be useless to bring the question to a division; although a midwife had been given an allowance after a shorter service a couple of years before because she had the necessary religious qualification.

Condurango in the Treatment of Cancer.

DR. ISCHENSCHMIDT reports in the *Ärztlichen Intelligenz-Blatt*, September, 1883, that both Professor von Nussbaum, of Munich, and Professor Friedreich, of Heidelberg, have obtained "splendid examples of improvement in cases of cancers of the breast, of the stomach, and other parts, after the administration of condurango." In some cases a decoction of the root is given—30 parts, to water 100—one tablespoonful three times a day; in others the bark is the part employed. Goulard's extract is applied locally. They have not succeeded in effecting a cure, but "considerable improvement" has been brought about, and the patients have been placed in a "tolerable condition." The drug has, however, to be persevered with, not for weeks but for months.

The Queen's College, Cork.

WE understand that the Visitors of the College met at the Lord Chancellor's rooms in Dublin Castle to consider the expediency of a visitation to Cork with reference to the recent insubordinate proceedings in the College. It was eventually decided that the visitation should be granted and should take place on the 15th of May. The visitors are the Lord Chancellor, the Duke of Leinster, and the Presidents of the Colleges of Physicians and Surgeons in Ireland.

Phosphorus in Rickets.

DR. KASSOWITZ, of Vienna, after studying the effects of phosphorus on the bones of growing animals, has been led to administer it to large numbers of rickety children, with results that are apparently exceedingly favourable. He gives the drug in olive or cod-liver oil, 0.01 to 100, or 1 part in 10,000. Of this he gives a teaspoonful daily. The children treated in this way were 560 in number. Craniotabes disappears in from four to eight weeks, laryngeal spasm in cases of cranial rickets becomes less frequent in a few days, and ceases in a few weeks. Rachitic symptoms in the thorax and spinal column take a longer time, but even marked lateral curvatures in the course of a few months can no longer be detected. The most striking effects, however, are shown in the cases of those children who for years have not been able to stand or walk, but have been constantly compelled to lie or sit with their legs drawn up. In the course of one or two months such children have attained the use, whether for support or movement, of their lower extremities. We venture to express the hope that the picture is not too brightly coloured.

Delirium Tremens in a Child.

A REMARKABLE case has recently occurred in Dublin, in which a boy of eight years of age had stolen a considerable quantity of whisky and drunk it, thereby acquiring an attack of delirium tremens which nearly killed him. It appears that there was no mistake in the matter, the child being a veritable dipsomaniac from the time that he was able to imbibe alcohol in any form.

Median Section of an Advanced Pregnancy.

HERR WALDEYER, Professor of Anatomy in the University of Berlin, recently had the opportunity of making a median section of a woman who was expecting her confinement in a week. By thoroughly freezing the body he was enabled to get a beautiful and smooth section of every organ and part in the exact position they occupied during life. The child lay in the first breech position. The attitude was remarkable. The head was inclined to one side, and at the same time rotated on its axis. All the parts lay pressed so closely together that the problem how the human body can be best pressed into the ovoid form was beautifully illustrated. It is to be hoped that photographs of this interesting specimen were taken for the benefit of such as were unable to view the actual.

An Aseptic Suture Material.

DR. PARTSCH, first assistant in the Royal Surgical Klinik, Breslau, recommends ordinary sewing or purse silk rendered aseptic by a simple method devised by himself. The silk is soaked for 48 hours in a solution of iodoform in ether (10 per cent.). It is then taken out placed between layers of clean blotting paper and dried. In using any of the silk thus prepared, every care must be taken to prevent any contact of the part remaining unused with blood or secretions, and with this object in view he has the silk wound on a spool enclosed in a case perforated at the side to allow the thread to be passed through. He claims that silk thus prepared is thoroughly aseptic, and that pus will not form along the suture tracks.

Election of President to the Royal College of Physicians of London.

It affords us much pleasure to announce that Sir William Jenner, Bart., K.C.B., M.D., was unanimously re-elected President of the College, at a meeting of the Fellows on Monday last. It was at one time feared that the heavy and responsible duties connected with Royalty which devolve upon Sir William would preclude his re-acceptance of the presidential honour, and we are the more delighted that one who so ably and consistently supports the dignity of the College will be found at its head during the present crisis.

Death of Mr. Peter Squire.

A ONCE prominent figure before the medical and scientific world has just passed away in the person of Mr. Peter Squire, whose death at the ripe age of 85 occurred at his residence in London on Sunday last. Deceased, though not a member of the medical profession, was probably as widely known therein as any one of its most eminent members, and those who had the pleasure of his personal acquaintance will, by the death of Mr. Squire, mourn the loss of a friend of great scientific attainments, original mind, and nobility of character not often combined. Of his original work in chemistry the profession is already aware, whilst the value and popularity of his writing is attested in his "Companion to the Pharmacopoeia," a work which has attained a greater success than any other medical work in existence, and also his "Pharmacopoeia to the London Hospitals." Mr. Squire was appointed Chemist to the Princess Victoria in 1836, and in 1837 he received the appointment of Chemist in Ordinary to Her Majesty. He was one of the founders of the Pharmaceutical Society of Great Britain, and from its foundation in 1842 was its Examiner in Botany. He was thrice elected President. Mr. Squire took an active part in establishing the College of Chemistry, now incorporated with the Royal School of Mines, and at a time when there were separate Pharmacopoeias for England, Scotland, and Ireland, he earnestly advocated the consolidation of the three into one. In all that he undertook success attended him, and sustained by a vigorous constitution and a mind conscious of its own rectitude, he attained to a ripe old age, and has died full of that true respect and admiration which is ever cheerfully accorded to men of the calibre of Peter Squire.

WE hear that Dr. Tucker Wise is bringing out a new edition of his Alpine climate series, in which the name of the new Alpine establishment on the Maloja Plateau figures very prominently.

A MELANCHOLY suicide was committed by a surgeon—Mr. Wm. Wells, of Cricklade, Wilts—on Monday last. Deceased, who was between 70 and 80 years of age, was a landed proprietor, but had been much depressed of late, owing to agricultural losses. In the afternoon he settled some legal matters at his solicitor's, and then in the office swallowed some cyanide of potassium, from which he shortly died.

SIR JOSEPH LISTER, F.R.S., will take the chair at the twenty-second festival dinner in aid of the Royal Medical Benevolent College on May 7th, at the Langham Hotel.

DEPUTY SURGEON-GENERAL THOMPSON has proceeded from Aldershot to Dublin, having been promoted to the post of Principal Medical Officer of that district. He is succeeded at Aldershot by Deputy Surgeon-General R. Wolseley.

THE Earl of Miltown has given notice in the House of Lords that, on reassembling after the holidays, he will move that "the existing state of the Lunacy Law is eminently unsatisfactory, and constitutes a serious danger to the liberty of the subject."

To the mountain of floral tributes sent for the coffin of H.R.H. Prince Leopold was one from the patients of the Chelsea Hospital for Women, of which institution the Duke of Albany was the patron. The wreath, which was composed of violets and gardenias, was suggested and subscribed for by the patients themselves, and was accompanied by an address of condolence to the Duchess of Albany.

IN the principal foreign cities the rates of mortality per 1,000 of the various populations were, according to the latest official returns, as follow:—Bombay 26, Madras 55, Paris 26, Geneva 45, Brussels 26, Amsterdam 25, Rotterdam 21, The Hague 22, Copenhagen 22, Stockholm 26, Christiania 35, St. Petersburg 44, Berlin 22, Hamburg 26, Dresden 23, Breslau 33, Munich 30, Vienna 30, Prague 39, Trieste 40, Turin 43, Venice 28, Lisbon 34, New York 24, Brooklyn 16, Philadelphia 21, and Baltimore 22.

Scotland.

[FROM OUR NORTHERN CORRESPONDENTS.]

ALARMING FIRE IN GLASGOW ROYAL INFIRMARY.—On Thursday morning last, at about a quarter to four o'clock, a fire of a very alarming nature was discovered by the inside watchman to have broken out in a store in connection with the Royal Infirmary. Alarm was immediately raised, and by the time the engines had arrived the fire was found to have got a good hold, and the efforts of the men were directed to the protection of the buildings on each side of it. In this they were completely successful, but the store was entirely gutted. The destroyed building was used principally for the storage of provisions, and on each side of it were Nos. 1 and 2 wards, which are devoted to medical cases only. When the alarm was raised, many of the patients became panic-stricken, and three of these—two women and a little girl—made their way on to the roof of the front building in Castle Street. In their terror they were about to jump into the street, but, fortunately, a cab was passing at the time, and the driver, seeing the perilous position of the females, drew up his cab on the pavement close to the building, and, with the aid of two passers-by, rescued them from the roof of his cab. Fortunately, no one was injured, and the fire was confined to the spot where it originated.

RICKETS IN GLASGOW.—At a meeting of the Philosophical

Society of Glasgow, held on the 2nd inst., Mr. James Thomson, President of the Biological Section, read a paper on "The Prevalence of Rickets in the City of Glasgow and in the West of Scotland, and the relation of Rickets to the Food and Water used." At the outset he pointed out that the number of deformed children had greatly increased in Glasgow of late years, and stated that some people believed that this circumstance was traceable to the absence of lime in the Loch Katrine water. Another reason assigned was the great change that had taken place in the character of the food supplied to young people. He showed that in recent years the consumption of tea and sugar had largely increased among the working classes, while there had been a great falling off in the quantity of oatmeal used, and hinted that this change had had a good deal to do with the increase of rickety children. He was of opinion that if there was more attention paid to diet, and greater care exercised in the cooking of simple plain food, there would be fewer deformed children in our midst. Mr. Thomson then stated the results of his visits to various localities, which he had been carrying on since the summer of 1881, entering into detail as to the certain kinds of deformity under which the children laboured. Another cause for the prevalence of rickets he attributed to the early weaning of children, for they were seldom seen in localities where children were long nursed, and that stood to reason, for the blood could not yield what it had not got. Another cause was, he believed, the deficiency of lime salts in the water used, and though the effect might be infinitesimal, still it would be better if some remedial measures could be adopted. In the course of the discussion which followed the reading of the paper, Professor M'Kendrick said he had given some attention to this matter, and the impression he had come to was that the number of rickety children was principally owing to the kind of food employed, and not so much owing to the water supply.

INFECTIOUS DISEASES IN EDINBURGH.—At a meeting of the Town Council's Public Health Committee, on the 1st inst., the Medical Officer of Health stated that during the past month 579 cases of infectious disease had been reported—measles, 363; scarlatina, 153; typhoid, 36; diphtheria, 22; typhus, 5. Of the measles 135 occurred in the New Town, 109 in the Old Town, and 119 in the southern suburbs. In the course of the three months ended 31st March there had been 2,375 cases of infectious disease—1,037 in January, 759 in February, and 579 in March. The cases of measles alone during the quarter amounted to 1,709, 706 being in the New Town, 563 in the Old Town, and 440 in the southern suburbs. Of typhoid there were 88 cases, 25 being in the New Town, 54 in the Old Town, and 9 in the southern suburbs. The scarlatina cases numbered 197 in the New Town, 202 in the Old Town, and 119 in the southern suburbs. On the 1st inst. there were 81 cases of infectious disease in the various hospitals in the city, as against 114 a fortnight ago. In the City Hospital there were 23 cases, Old Infirmary 45, and Sick Children's Hospital 13. Of these, 17 were typhus, 13 typhoid, 45 scarlatina, 3 measles, and 5 erysipelas.

THE EDINBURGH UNIVERSITY TERCENTENARY FESTIVAL.—The honorary degree of LL.D. will be conferred upon the following members of the profession, in addition to those reported in our last issue, at the approaching Tercenary Festival:—Sir William W. Gull, Bart., D.C.L.; Dr. Henri Gueneau de Mussy, Académie de Médecine, Paris; Dr. W. O. Priestley, London; Dr. John Smith, F.R.C.S., F.R.S.E., President of the Royal College of Surgeons, Edinburgh; Professor Ussing, Copenhagen.

PRESENCE OF STUDENTS AT THE COMMEMORATION OF THE TERCENTENARY.—The following official notice, by Professor Wilson, secretary to the Senatus, has been posted at the University:—"The numbers of tickets allotted to students for the undermentioned meetings are:—April 15—For the reception by the Lord Provost and the Town Council, 450. April 16—For the service in St. Giles', 250; Volunteer guard, £5; for the conversazione, 250; choir, 60. April 17—For the Tercenary celebration, 250. These tickets will be handed over to the Students' Representative Council for distribution."

PROGRAMME OF THE TERCENTENARY FESTIVAL.

THE following may be taken as the final arrangements for the Tercenary which takes place next week:—

Tuesday, 15th April.—Reception of Guests, Members of the University, and others, by the Lord Provost, Magistrates, and Town Council, in the Museum of Science and Art, from 8 to 10.30 p.m. The Ordinary University Graduation Ceremonial will take place in the United Presbyterian Hall, at 11 a.m. The Address to Graduates will be delivered by Professor Calderwood. Tickets may be obtained from the Secretary of the Senatus. Students' torchlight procession, 11 p.m.

Wednesday, 16th April.—Commemoration service in St. Giles's, at 11 a.m. Luncheon in the University New Buildings, by invitation of the Principal and the Professors of the Faculty of Medicine, at 1 p.m. Dramatic entertainment by the students, in the Theatre Royal, at 3 p.m. Organ recital by Professor Sir Herbert Oakeley, in the music class room, Park Place, at 4 p.m. Conversazione in the hall of the University Library, 8 to 11 p.m. Ball, given by the students in honour of the stranger guests of University, in the Assembly Rooms, George Street, at 10 p.m.

Thursday, 17th April.—The Tercenary Ceremonial, in the United Presbyterian Hall, Castle Terrace, at 10.30 a.m. A. Reception of Delegates from Universities and other learned bodies. B. Honorary Degrees conferred in Divinity and Laws. C. Tercenary Address by the Chancellor of the University. Luncheon by invitation of the President and Fellows of the Royal College of Physicians, at 1.30 p.m. Reception by the Dean and Faculty of Advocates, in the Advocates' Library, at 3 p.m. Reception by the Royal Medical Society, Melbourne Place, at 3 p.m. Tercenary Banquet, Drill Hall, Forrest Road, at 6.30 p.m.

Friday, 18th April.—Breakfast by invitation of the President and Fellows of the Royal College of Surgeons, at 10 a.m. Visits to the Holyrood Palace, the Castle, University Buildings, &c., and excursions. Concert under the auspices of the University Musical Society, in the Music Hall, George Street, at 2.30 p.m. Reception by the President and Council of the Royal Scottish Academy, at 4.30 p.m. Illumination in Princes Street, and fireworks on Castle Esplanade, 9 to 10.30 p.m. Students' Symposium in the Drill Hall, Forrest Road, at 10 p.m.

Literature.

PORRO'S OPERATION. (a)

THE publication by Dr. Clement Godson of his Introduction to a Discussion on Porro's Operation is extremely opportune as an accompaniment to the record of his successful case of a true Porro's operation. This reprint will be very welcome to all who are interested in the progress of abdominal surgery; while those who in the future seek to attempt the saving of maternal and infant lives by this method cannot fail to recognise the immense advantage which must accrue to them from the study of Dr. Godson's communication. The case itself is described fully, and every detail of importance in the operative procedure very lucidly expressed. As an addendum, the operator has, with indefatigable labour and perseverance, compiled an unique amount of statistical information respecting Porro's opera-

(a) "Porro's Operation." Introduction to a Discussion in the Section of Obstetric Medicine. By Clement Godson, M.D. Reprinted for the author from the *British Medical Journal*, January 26th, 1884.

tion, and a report is given of the important and practical debate which followed the delivery of Dr. Godson's introduction to the discussion in the Section of Obstetric Medicine.

Rather more than a hundred years have elapsed between the time when Cavallini, in 1768, published his "Medico-Chirurgical Experiments on the Successful Excision of the Uterus in Certain Animals," and the fulfilment of the hope he then expressed, that they might benefit a "future and more fortunate generation;" for it was not until 1876 that Porro performed the first successful operation on the human subject, the lives of both mother and child being saved thereby.

Dr. Godson rightly pleads that, in order to form a just and fair estimate of the position Porro's operation holds now, and is to occupy hereafter, in the domain of abdominal surgery, statistics must be based upon a thorough appreciation of what a Porro's operation is. It is thus defined:—"Caesarean section, followed by removal of the uterus, together with its appendages, including the ovaries, leaving only the cervical portion of the uterus;" and in order to prevent confusion upon this point in the future, Dr. Godson has prepared three exhaustive tables of statistics, as follows:

1. True Porro's operations.
2. Utero-ovarian amputations performed during pregnancy, but before the fetus was viable.
3. Operations for removal of fetus from abdominal cavity by laparotomy, followed by amputation of ruptured uterus, with ovaries.

The force and significance of clearly differentiating between these varieties of operative procedure will become apparent to the reader if he will carefully study the tables of statistics in the light of Dr. Godson's remarks upon them, and his own successful operation.

A not unimportant feature of the reprint is the record of the discussion which followed upon Dr. Godson's introduction to the debate.

With these remarks we conclude, feeling assured that all who desire the advancement of abdominal surgery will not fail to make themselves acquainted with the details of Porro's operation by reading Dr. Clement Godson's reprint for themselves.

Correspondence.

TRANSFUSION.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—The author of an annotation in your issue of March 26th (p. 291), seems much perturbed in mind that the good work done by Dr. Little, with respect to the intravenous injection of saline fluid, should have received inadequate recognition in my monograph "Transfusion" (Baillière, Tindall and Cox); and regret is also expressed that Dr. Little's merits should have been passed over by a pupil of the very hospital with which he has been so honourably associated.

It is quite true that the name of this eminent physician has been accidentally omitted in the bibliography appended to the book—an error, which, among other shortcomings, will be rectified in the third edition, now in course of preparation.

I am indebted for being told that some of Dr. Little's important contributions will be found in the London Hospital Reports; but the information is superfluous, since this reference, together with the number of the volume (1866), containing the papers, occurs at least twice in my work; wherein and elsewhere, the rationale of Dr. Little's method has, in point of fact, been adduced as one of the chief arguments on which transfusion for hæmorrhage should be based.

Since, also Sir Spencer Wells, in his special preface to my book, writes:—"Dr. Little's trials at the London Hospital encouraged me to follow his example. . . .," the fallacy of the criticism is at once apparent.

I am, yours, &c.,

CHAS. EGERTON JENNINGS.

University of Durham College of Medicine,
March 31st, 1884.

Medico-Parliamentary.

HOUSE OF LORDS.—THURSDAY, APRIL 3.

MEDICAL ACT AMENDMENT BILL.

LORD CARLINGFORD presented a petition from the British Medical Association, praying that this Bill might be passed into law during the present session. The noble lord formally moved the third reading of the Bill.

The Earl of CAMPERDOWN took occasion to remark that this Bill was a compromise between the opinions of those who held that all medical authorities ought to preserve complete liberty in giving their licences and the opinions of those who considered that the licences should be given after the examinations. There were one or two points to which he should like to refer; one in reference to the Scotch universities who had made their statement through Lord Balfour of Burleigh. They had protested; not, however, with the intention of opposing the Bill in another place. He hoped they would realise what would be the effect of their opposition, if it were successful. It went to the root of the whole Bill. If the Scotch universities were to be allowed to retain the power of giving a licence, the English and Irish universities would demand the same privilege. One reason why the medical students had preferred to go to the Scottish corporations, in preference to other bodies, for their licences, had been on account of the excellence of the examinations there; and now that there were to be approximate examinations elsewhere, it was only to be supposed that many students would take the opportunity of going where they could get the best education. For this reason, if not for any other, he believed the Scottish universities were not well advised in raising their objection. He thought the Lord President, in dealing with the claims of the various bodies, had gone to the furthest extent of conciliation. He had given the corporations more representation in proportion to the universities than he had proposed to do in the Bill of last year. They had, for the future, a guarantee in the examinations which were to be conducted by an authority for the whole kingdom, which they had not had hitherto, that the examinations of the Scottish corporations would be good for the future; and even supposing that that were not to be the case, there was a power of revision in the Bill which would enable the Privy Council and the Medical Council together to make changes hereafter in the representation of the various authorities upon the medical boards. Under all these circumstances, he was quite ready to accede to the change which it was proposed to make in the Bill, and he thought the Scottish medical corporations would be very ill-advised indeed if they proposed to force the changes further in the House of Commons. The evidence taken before the Royal Commission showed very distinctly—and the testimony was of the most incontrovertible character, namely, that of the crammers—that hitherto the examinations of some of the Scottish medical corporations had been very inferior to those held at other medical centres in other portions of the United Kingdom. In dealing with the corporations as the Lord President had done, he had taken a very favourable view of the case. There was only one other matter to which he wished to allude. A proposal had been put forward by the Irish medical corporations, in the form of an amendment, which was ultimately not pressed, to the effect that all students shall be compelled, directly or indirectly, either before the time of obtaining their licence or afterwards, to be affiliated to some medical corporation or university. Any claim of that sort, should it be hereafter revived, would, he hoped, not be listened to for a moment. This question of compulsory affiliation had been put forward again and again, and had been considered by the Royal Commission and in their lordships' House, but on no occasion had it been successful, and he wished to remind those who supported this contention of the fact, which very likely had not occurred to them, that an objection was raised to the Bill from an exactly opposite point of view. There was a powerful party who were displeased with the Bill because, although it instituted a board of examination, it did not create any title for those who passed the examinations, and he dared say an attempt will be made to create a new title. Now that point, also, was considered by the Royal Commission, and he was bound to say that he himself cordially concurred in the decision arrived at that it was inexpedient to make any addition to the already existing titles. This Bill, as he had said, was a compromise. It took

away from all the universities and medical corporations the privilege of giving licences, a privilege which they were naturally all very reluctant to give up; but at the same time they had nearly all been so good as to accede to the proposal of the Royal Commission, which was contained in the Bill. There was every reason to believe that the Bill in its present form had the approbation of a very large majority, both of the universities and of the medical corporations. He endorsed the statement of the Duke of Richmond and Gordon, and he hoped the Government would press the Bill forward as much as they possibly could in the House of Commons. He did not himself believe that the opposition would be of a very strenuous character; but at all events the proposals could be discussed in a very short space of time.

LORD CARLINGFORD: I am very glad the noble earl should have given his blessing to this Bill before it leaves your lordships' House to encounter the dangers of another place; and I am very glad that he should have given the weight of his authority and that of the Royal Commission against certain changes which have been much talked of and desired in certain quarters, and which are liable to be debated in that "other place." I am not surprised that the noble lord should have said what he has, because, in the report of the Royal Commission, it appears they most carefully considered the statements and views of the Scottish Universities, and they gave the most cogent reasons why it was absolutely impossible that the Scottish Universities could be treated on an exceptional footing, and be put in possession of a totally exceptional privilege as compared with the other universities of England and Ireland. As to the Bill itself, I am convinced that it runs no danger whatever so far as public opinion or professional opinion is concerned.

The Bill was then read a third time.

Before the question, "That the Bill do pass," was put, **LORD CARLINGFORD** moved an amendment to Clause 9, to give the Royal Irish University four, instead of three, representatives on the Irish Medical Board.

The **Earl of MILLTOWN** declared that the Irish Medical Corporations were by no means satisfied with this amendment.

After a few words from **Earl CAIRNS** in support of the amendment, **LORD CARLINGFORD** defended his proposal. He said there had been a strong feeling on the part of the Irish College of Physicians that they should be put on the same footing as the Irish College of Surgeons; and he was satisfied that it would be better to do that. It was always assumed, and it had his full concurrence, that the Irish Universities should be maintained in their majority on the Board. He had attempted to deal with the matter by giving a member to the two universities, either to be elected conjointly or to be elected alternately, but that plan was thoroughly distasteful to both the universities; and it had only remained for him to settle the matter by proposing to give a member to each. It came to this, that the majority that was to be maintained on the side of the Universities was to be a majority of two instead of one.

The amendment was agreed to, and the Bill then passed.

Pass Lists.

University of Edinburgh.—The following candidates have passed the recent first professional examination:—

Messrs. O. M. Allan, C. A. Anderson, D. H. Anderson, J. J. André, Alexander Asher, Benjamin Barnard, R. H. Beardsley, G. T. Beaton, Walter L. Bell, William Bell, W. W. O. Beveridge, H. L. Blacklaw, M. B. Burton, W. S. Bower, A. D. Fleming, D. A. Fraser, W. M. Gabriel, T. H. Gee, R. W. Gibson, George Hall, C. W. Hayward, Andrew Hestager, Thomas Ireland, H. R. Kenwood, George Knowles, J. R. Lownds, William J. Lewis, John Macdonald, George S. Macgregor, Henry Mackay, Donald M. Macleachlan, A. A. Macleod, H. W. G. Macleod, John M'Naughton, F. A. Holmden, W. Grant Macpherson, W. B. Paterson, W. A. Mackintosh, W. G. Magee, Alfred Mann, Alan Matheson, S. W. Mathias, T. G. Meikle, Thomas Melring, A. van der Merwe, J. G. Moffat, James Moir, H. H. Montgomery, T. L. Morgan, F. H. Morrison, R. H. Morrison, P. R. Morrison, John M'Andrew, M. F. X. Nalletamby, W. S. Nason, A. B. Northcote, G. J. L. O'Neill, William O'Rourke, J. C. Palmer, S. C. Paton, J. A. Perez, A. F. R. Platt, J. F. Priddle, G. M. Rae, Charles Reid, Henry Robinson, A. R. Russell, J. S. E. Russell, G. S. Samuelson, H. C. L. Scofield, Frederick Smith, J. H. Slayter, Charles Stewart, W. R. Taylor, A. D. Varton, A. H. Vassie, Thomas Walcott, O. R. M. Wood, E. D. Wellburn, George Wilson. **Messrs.** J. A. Lawson, and Charles Macleod have passed in botany, zoology, and chemistry for the first B.Sc. examination.

Medical News.

Medical Sickness, Annuity, and Life Assurance Society.—A meeting of the Provisional Executive Committee was held at 38 Wimpole Street, on Thursday, March 27th, when there were present—Mr. Sibley, Dr. Clibborn, Mr. Fredk. Wallace, Mr. Major Greenwood, Mr. J. Brindley James, Mr. Radley (Secretary), Mr. E. Noble Smith (in the chair). The Secretary presented his report, showing a total of 333 members, and receipts of the preliminary entrance fees, &c., to the amount of £228 2s. 6d. A letter was read from Dr. J. D. Plunket, President of the Tennessee State Board of Health, Nashville, U.S., asking for copies of the rules, tables, &c., of the Society, as a model for the formation of a similar society in connection with the Tennessee State Medical Association. The Secretary was requested to forward copies of the documents. A communication was read from Mr. Gilbert Walker, the Editor of the *British Journal of Dental Science*, raising the question whether dental surgeons or dentists, either qualified or unqualified, or both, would be eligible as member of the Society. The question, which was thought to be an important one, was discussed at some length, and the following resolution, proposed by Mr. Sibley, was unanimously passed:—"That any qualified registered dentist holding the diploma of L.D.S. of the Royal College of Surgeons of England, Scotland, or Ireland be eligible as member of the Society." The Secretary was desired to forward a copy of the resolution to Mr. Walker, with a request that he would bring it before the notice of the dental profession through the columns of the *British Journal of Dental Science*. Letters were also read from Mr. J. Bain-Sincock and others, containing suggestions, the consideration of which it was decided to postpone until the general meeting, when full opportunity will be afforded for the discussion of any question the adoption of which would necessitate an amendment of the Rules. The Secretary read the draft copy of a circular drawn up in accordance with a resolution passed at the last meeting, in which the history, objects, and benefits of the Society are clearly laid down, which was approved and ordered to be circulated, as arranged. The consideration of the proposal forms, brought forward for the decision of the Committee, brought the proceedings to a close.

Notices to Correspondents.

MR. HARRINGTON (Manchester).—The prizes are £700 for the first, and £300 for the second; these will be adjudicated on a very practical basis. Each competitor will have to send in a statement of ingredients used in the competing drink, and will have to submit a sample of not less than three gallons of the manufactured article for testing purposes. The greatest difficulty we conceive in complying with the terms of competition will be in keeping the cost of manufacture down to 2s per 100 gallons English measure. Detailed particulars can now be had of the Secretary to the Association, 55 Chancery Lane, London.

APPRECIABLE CONCESSIONS BY AN ASSURANCE COMPANY.

At the recent general meeting of the Railway Passengers' Assurance Company, the Chairman stated that the following important concessions would be made to the holders of General Accident Policies:—"Immediate payment of the sum assured in case of death. Accidents causing loss of sight of both eyes, or of two arms, or of two legs, would be deemed equivalent to a fatal accident. The restriction of the amount assured to £1,000 would be withdrawn as regards Railway Accident Assurance, so that a Journey Insurance Ticket or Policy might be taken at the Railway Station."

The Company find that one Policy in every twelve becomes a claim each year, and they have now paid no less than two millions sterling as compensation; certainly a sad corollary on railway travelling.

DR. LAFFAN.—Your case is marked for early insertion.

A YOUNG PRACTITIONER.—You must attend if summoned, but you can afterwards sue. Will reply more fully in our next.

DR. J. W.—Your letter is unfortunately crowded out of our present number.

THE ROGERS TESTIMONIAL FUND.

We are requested by the Hon. Sec., Dr. Wickham Barnes, to insert the following final list to this fund:—

Dr. Danford Thomas ..	£1 1 0	A Pauper ..	.. £0 2 0
G. Terry, Esq. ..	.. 1 1 0	Dr. Hawksley ..	.. 1 1 0
Dr. G. Barnes ..	.. 0 10 6	Dr. Gourley ..	.. 1 1 0
Thos. Davies, Esq. ..	.. 0 5 0		

The Honorary Secretary requests all subscribers who have not yet sent him their promised donations kindly to do so at their earliest convenience, addressed, Dr. J. Wickham Barnes, Poor-law Medical Officers' Association, 8 Bolt Court, London, E.C.

THE BOYCOTTING OF MEDICAL ASSISTANTS.

To the Editor of the MEDICAL PRESS AND CIRCULAR.

SIR,—In reference to Mr. Baxter Langley's letter in your journal of the 19th ult., "that there is a prejudice in England against the employment of Irishmen as medical assistants," I think it right to state that I believe such a feeling is not general amongst the profession in England.

Some months ago a letter appeared in the *Medical Times and Gazette* inquiring whether there was an agency in Ireland through which *locum tenens* and medical assistants could be secured. To this letter I replied, stating that, as there was no such agency, I should be glad to supply the names of several highly qualified gentlemen willing to undertake such duties without charge to either side for my trouble. To this letter I received several applications from London and from all parts of England from gentlemen in want of assistants, &c. This, together with the knowledge that within the past few months some dozens of Irishmen have been engaged as assistants, and taken as partners to extensive practices in various parts of England, will, I trust, refute the insinuation that such narrow-minded bigotry exists amongst members of the medical profession.

Royal College of Surgeons, Dublin,
April 4, 1884.

Yours, &c.,
G. F. BLAKE.

INQUEST WITNESSES.

G. S. K. says: A patient whom I was attending had weak action of heart, with dyspnea, &c. I informed the friends he was in a dangerous state, and might die suddenly, and his clergyman informed the patient. About ten days after my last visit (but still under my treatment) he was found dead in his bed. The constabulary called, were informed of all the facts, my opinion, &c. They reported to the Coroner (who has since stated to me he directed them to summon all necessary witnesses). I was not summoned or informed by them; and if an inquest was considered necessary in this case, ought not I to have been a witness, being the only one who could give evidence as to the state of the patient, that of the friends being only secondary from my opinion.

[The Coroner is bound to summon a "legally qualified practitioner in actual practice at or near" the place of death. Any witness answering this description may be legally employed, though it is obvious that the intention of the Act was that the practitioner last in attendance on the deceased should be called. On the other hand, if the Coroner summoned a person not answering the description set down in the Act, the fee to be paid to his witness might be traversed before the Judge of Assize, and would probably be disallowed. This is the only remedy available.—ED.]

DR. P. J. MACNAMARA (Bruff).—Thanks for your note of Dr. Donovan's case. We hope to publish it shortly.

DUBLIN.—Your position will not be in any way affected should the Bill pass into law. Thanks for the cases, none of which have as yet been published. The post was delayed.

THE PAUPERISING EFFECTS OF LONDON HOSPITALS.

A "PROVINCIAL SURGEON" thus expresses his views of the outpatient difficulty, to which we referred in a leader last week: It is my full belief that not 2s. 6d. out of every £1 expended in London hospitals goes to any deserving object, that the existing system pauperises the middle-class population, misappropriates the money of the charitable, and robs the profession. Were I worth millions, I would not give a sixpence to one such institution. I have seen, in London hospitals, multitudes of out-patients who have no more right to gratuitous advice, or medicine, or nursing, than any shopkeeper or professional man. If the medical staffs and governors of hospitals cared to put a stop to this sort of thing they could do it readily by refusing hospital aid to all who could not show cause. A printed form, signed by a clergyman, magistrate, medical man, or subscriber to the hospital, stating that they knew the patient to be "incapable of paying for medical advice and medicine," would fix most of the cases. But—in truth—the hospital authorities are not in earnest about it. The whole system is rotten, and will continue rotten as long as so many charitably-minded but misguided people are forthcoming to give their money in this sort of pseudo-charity without inquiring as to its application. The expenditure is extravagant and the recipients commonly undeserving.

MR. RICHARD GERNER (Westbourne).—We shall be happy to look through your paper if you will send it, but scarcely expect to find therein matter which shall ensure its appearance in our columns. It is contrary to our custom to insert contributions from lay readers, as we cannot reasonably conceive their ability to instruct the profession on subjects which are its especial study and concern. We have no knowledge of "the celebrated medical writer" who advised you to send us the MSS.; nor on reference to the official Medical Register can we find his name.

MR. GREEN.—Your application shall be considered, but just now there are several gentlemen who have asked for a similar concession.

MR. WALTERS.—We believe that no other hospital exacts the same objectionable proof of attendance; and probably no other students would tolerate a system which degrades them to the level of journeyman labourers at a factory.

RES CONCEPTA.—Your suggestion to give College lectureships to the most competent men for the posts smacks of Arcadian simplicity. You ought by this to have discovered that these offices are regarded in the light of bread-procurers for needy members of the junior staff: not a few of whom, indeed, would be sorely put to it to make a living were merit to dictate such elections. Your hospital is probably an average sample of the arrangement.

Meetings of the Societies.

WEDNESDAY, APRIL 9TH.

HUNTERIAN SOCIETY.—At 7.30 p.m., Council.—At 8 p.m., Dr.

Stowers, Sequel to a Case of Paget's Disease of the Nipple.—Mr. Rivington: (1) Case of Recent Fracture of the Patella treated by Wire Suture; (2) Case of Wound of Knee-joint.—Dr. Herman, On Prolapse of the Pelvic Floor, without Relative Displacement of the Uterus.

EPIDEMIOLOGICAL SOCIETY OF LONDON.—At 8 p.m., Mr. Bolton G. Corney, On the Behaviour of Certain Epidemic Diseases in Natives of Polynesia, with especial reference to the Fiji Islands.

ROYAL MICROSCOPICAL SOCIETY.—At 8 p.m., Dr. W. B. Carpenter, On Binocular Vision with the Microscope.

Vacancies.

Alton Rural Sanitary Authority.—Medical Officer of Health. Salary £20. Applications by April 23.

Birmingham Midland Eye Hospital.—Dispenser. Salary, £70, with dinner daily. Applications to the Secretary before April 15.

Chatham, St. Bartholomew's Hospital.—Assistant House Surgeon. Salary, £100, with board, &c. Endorsed applications to be sent in by May 1.

Coombe Hospital, Dublin.—Assistant Master. Applications to Master, or at Coombe Hospital.

Durham County Hospital.—House Surgeon. Salary, £100, with furnished rooms, &c. Applications to the Hon. Sec., 10 South Bailey, Durham, by April 15.

Flintshire Dispensary.—House Surgeon. Salary, £100, with furnished house, &c. Applications to the Secretary by April 15.

Oxford, Warneford Hospital.—Assistant Medical Officer. Salary, £100, with board, &c. Applications to the Medical Superintendent by April 12.

Royal Free Hospital.—Junior Resident Medical Officer. Board, but no salary provided. Applications to the Secretary before April 15. (See advt.)

Appointments.

BUXTON, D. W., M.D. B.S., M.R.C.P. Administrator of Anæsthetics at the Hospital for Women, Soho Square.

EVANS, W. A., M.R.C.S., District Surgeon to the Salford and Pendleton Royal Hospital.

GOSTLING, W. A., M.R.C.S., House Surgeon to University College Hospital, London.

HARPER, G., M.B., Assistant Physician to the Chelsea Hospital for Women.

KEBBELL, C., M.R.C.S., Junior House Surgeon to the Sussex County Hospital.

KIRBY, E. D., M.B., C.M. Ed., M.R.C.S., House Surgeon and Secretary to the Bridgenorth Infirmary.

Love, J. H., M.R.C.S., L.S.A. Lond., Medical Officer for the First District of the Wolverhampton Union.

MASON, A., B.A., M.B. Dub., L.R.C.S.I., Assistant Resident Medical Officer to the Chorlton Union Hospitals, Withington.

MOGACHEN, F. W. D., L.F.P.S. Glas., Medical Officer to the No. 5 District of the Newport Pagnell Union.

MOULLIN, C. M., M.D. Oxon., F.R.C.S., Demonstrator of Anatomy to the London Hospital Medical College.

RABBETH, S., M.B. Lond., M.R.C.S., Senior Resident Medical Officer to the Royal Free Hospital, London.

SPOURLE, T. W., L.K.Q.C.P.L., L.R.C.S.I., Medical Officer to the Mirfield District of the Dewsbury Union.

STARTIN, J., M.B. Cantab., Honorary Surgeon and Lecturer to St. John's Hospital for Diseases of the Skin, London, has been appointed Honorary Consulting Surgeon to the Sheffield Public Hospital for Skin Diseases.

STRATHERS, G. N., M.R.C.S., L.R.C.P. Ed., Medical Officer to the Tenth and Eleventh Districts of the Wycombe Union.

TRAVES, F., F.R.C.S. Eng., Lecturer on Anatomy at the London Hospital.

Births.

DILLON-KELLY.—March 23, at 31 Earl Street, Mullingar, the wife of Dr. J. Dillon-Kelly, of a daughter.

MARTIN.—March 3, at 76 Brunswick Street, Sheffield, the wife of John W. Martin, M.D., of a son.

POPE.—April 3, at Norfolk Crescent, South Hayling, the wife of Percy Pope, M.R.C.S., L.R.C.P., of a son.

Marriages.

DENHAM—HOLMES.—April 3, at Rutland Square Church, Dublin, John Knox Denham, L.R.C.S.I., to Celia Mary, eldest daughter of Dr. Holmes, 67 Eccles Street.

NORRY—TOOBY.—April 3, at the parish church, Epsom, William Augustus Norry, M.B., M.R.C.S.E., of Epsom, to Annie Jane, youngest daughter of the late Henry Norton Tooby, Esq.

ROBINSON—RIPPON.—April 2, at the parish church, Stanhope, William Robinson, M.S., M.B., M.R.C.S., to Eleanor, eldest daughter of the late Valentine Rippon, J.P. of Frosterly.

Deaths.

GRANT.—April 2, at his residence, 4 Rehoboth Place, Dublin, John Grant, M.D., F.R.C.S.I., at an advanced age.

LASHMAR.—March 23, at Dover, Charles Michael Lashmar, M.D., formerly of Croydon, aged 80.

McDONALD.—April 1, at Landsore Villas, Teignmouth, Devon, T. W. McDonald, I.G., R.N., F.R.C.S.E., aged 80.

TAYLOR.—March 18, William Taylor, J.P., M.R.C.S. Eng., of Scarborough and Cloughton, aged 66.

THOMAS.—March 25, at Chatham, Edward Temple Thomas, L.R.C.S.I., C.M., aged 86.

RECENT ADVANCES IN PELVIC SURGERY. (a)

By LAWSON TAIT, F.R.C.S.,

Surgeon to the Birmingham and Midland Hospital for Women; Consulting Surgeon to the West Bromwich Hospital, &c.

(Continued from page 323.)

THE third group consists of two cases in which the uterine appendages were removed for menstrual epilepsy, that is for epilepsy centring round and apparently being produced by the period. The first case had all her life been an imbecile. When menstruation began fits came on, and they gradually increased in severity till she became a furious and unmanageable maniac, requiring the constant care of two attendants during the menstrual week. For that period she had constantly recurring fits of the severest kind. Her menstruation was extremely profuse. Removal of the appendages promptly stopped her periods and her fits, and now she has returned to her infantile imbecility, without any mania and without any fits. She chatters away good naturedly, and occasionally drops on the floor with a transient attack of "petit mal," and she has occasional outbreaks of temper. She is, however, an altogether changed being since the operation, nearly four years ago.

In the second case menstruation was quite as effectually stopped, and the fits were completely arrested for about five months, but they came gradually back, and I understand she is now as bad as ever. I am, therefore, under the impression that it is very doubtful if we have made any real advance in this direction. I have now operated on five such cases, and have to confess complete failure in two, partial success in another and satisfactory results in two.

The series includes two cases of pyosalpinx, the first cases of the kind on which I operated, and the details of both are of interest on that account alone, and

may, therefore, be briefly given. In the first case there was a history of sub-involution and retro-flexion, the latter condition having been mistaken, in all probability, by a physician who saw her, for "a tumour behind the womb." This gentleman introduced a sponge tent, and left it in her uterus for nine days. She had an extremely severe illness after that heroic or mistaken treatment. The full details of this history are given in the *British Medical Journal* for May 14th, 1881. On March 6th of that year I removed both Fallopian tubes, occluded and distended with large quantities of pus. The preparations are now in the Museum of the College of Surgeons. She made an easy and rapid recovery, and remains now in perfect health, nearly three years after the operation.

The second case was operated on June 13th, 1881, and the preparations are also in the Hunterian Museum. The trouble began after a miscarriage, about nine years before the operation. I removed all the appendages, and though the operation did not at once arrest menstruation, it completely relieved her severe sufferings. She menstruated irregularly till the following November, since which time it has been arrested, and she is now in perfect health.

In the list there are six cases of hydrosalpinx, and I think it will be sufficient if I give the details of two. The first occurred in an extremely handsome blonde, who was married when she was sixteen, and lived with her husband for three years only, procuring a divorce from him at the end of that time, but not before he had conferred the privileges of gonorrhoea upon her three times. After the second attack she never was free from pain till I removed a hydrosalpinx from her early in 1879. I meet her frequently now, and have the assurance that she is perfectly well—so well, indeed, that she has lately risked the perils of matrimony for the second time.

The second case is peculiar, in so much that it illustrates the dangers of this disease when left to itself, and the obscurity of its origin in many cases. In this patient

(a) Read before the Harvelian Society of London, March 6th, 1884.

no explanation of its origin could be suggested, and the reason of my research into its existence was the recurrence of a mysterious and very serious attacks of acute peritonitis. I found a mass behind the uterus, and somewhat to the right side, and I advised an exploration. In October, 1879, I found this to be the right Fallopian tube occluded and distended with serum. I removed it, and the patient has remained perfectly free from pain and peritonitis ever since.

The other four cases are also in perfect health. The two cases of removal of the uterine appendages for uncontrollable menorrhagia threatening life have already been published. The condition found was merely that the ovaries were studded with numerous small cysts, a state in which they very frequently are in bleeding myoma. I do not pretend to suggest how or why this causes menorrhagia, but the operation promptly arrested the flow in both cases, and has been completely successful.

Of the thirteen cases of myoma, the result has been brilliantly successful and permanent in every case. The menstrual hemorrhage has been completely arrested, and the tumours have lessened in all cases—in a few they have entirely disappeared. One patient has become insane, but as she was always queer, I do not attribute this condition in any way to the operation. I may here mention that after the removal of single ovarian tumours, double ovarian tumours, uterine appendages for myoma and pyosalpinx (in all seven cases), I have seen symptoms of melancholia come on during or very soon after the convalescence. In four the condition was transient, but in three it still remains, and the patients are inmates of asylums. The cases are too few to give any indication of being more than mere coincidences; yet they are sufficiently numerous to insist on attention being drawn to their occurrence. I shall give two cases in detail merely because they are the first two on the list.

One was a widow lady, *æt.* 47, placed under my care by Dr. Crowe, of Worcester, completely invalidated by profuse hæmorrhage due to a myoma. This hæmorrhage had lasted for ten years, and showed no sign of abating. Everything short of operation had been tried and failed, and on October 18, 1879, I removed the appendages. She made a slow recovery; but on May 18, 1880, I saw her at Leamington with Dr. Wellesley Tomkins, who had charge of the case after the operation, and I found her in perfect health and she had had no menstruation since the operation. She is now resident in the West Indies, and I am informed is in the enjoyment of perfect health.

The second case, of a lady, closely associated all her life with our profession, as the widow of a highly-respected member of it, and the step-mother of two gentlemen now practising. She had been from time to time under my care, during several years, for profuse menorrhagia, the loss being so severe as on more than one occasion to threaten her life. As time went on she got no better, and at the age of 52, after having waited in vain for any sign of an arrest of menstruation, I advised removal of the uterine appendages. Previous to this I need not say everything had been tried, and I had made two unsuccessful efforts to enucleate the myoma, which was not much larger than a cricket-ball. The operation was performed on March 30, 1879. A few insignificant appearances of the menstrual flow were made until the following February. After that she rapidly gained strength, and since then has led an active and a useful life. She is now in perfect health, and the tumour has almost entirely disappeared.

The greater number of the cases of pelvic abscess treated by abdominal section have been already published in detail, and of them I need only say that they are all now, and have continued since the operations, so far as their pelvic condition is concerned, in perfect health.

The chief interest exists concerning the last group, consisting of fourteen cases of chronic ovaritis, in all of

which the patients and their medical attendants have agreed with me that the sufferings of the patients were sufficient to justify their submitting to the slight risk attaching to the proceeding from which it was hoped they would obtain relief. It may be, and has been, argued that, as the sufferings arising from chronic inflammation of the ovary do not involve any risk to life, that therefore such operations are unjustifiable. The answer is simple, and to my mind conclusive, when it is stated that our function is not limited to the mere saving of life, but extends to the mitigation of suffering.

Merely premising that I know that complete relief has now been obtained in all of these cases, save one, of which I have lost sight, but that in some it was deferred for months, and in two for more than a year. I propose to give the history of two of the cases in which the delay almost made us feel that the operation had been unsuccessful. The first was a lady who had begun to menstruate at the age of 17, and at the onset had an illness, of which no very clear account could be obtained save the patient's recollection of great pelvic pain. Menstruation had always been regular, lasting for three days, and it had always been accompanied by great pain, the pain continuing after the period, so that for a week in each month her life was wretched. I saw her for the first time in 1877, and found the uterus completely retroverted and somewhat fixed. From that time till June, 1879, a great many different kinds of treatment were tried in vain, and at last I proposed to one of her relatives, a practitioner of medicine, that the radical cure of removal of the uterine appendages should be resorted to. He concurred in my proposal; but in that nothing should be left untried, I advised that the opinion of Dr. Matthews Duncan should be taken. I submitted a statement of the case to him, and he made an independent investigation of the patient's condition. The only result was that I received from Dr. Duncan a recommendation of general principles which had already been carried out to the full. Within a month both patient and friends determined for themselves that the operation should be performed, and I undertook it upon the 18th July, 1879. I found the uterus retroverted and adherent, and both ovaries also adherent to the posterior wall of the *cul de sac*. The ovaries were removed with a good deal of difficulty. The patient made an easy recovery, and went home early in August. But her menstruation went on at first regularly, and then somewhat irregularly, with almost as much pain as before the operation, so that in March, 1880, I feared that I should have to record a failure. In October she began to mend, and from November, 1880, to April, 1881, she had no period, she improved immensely in health, and could walk several miles without any discomfort, and this she had not done for many years before. But at the end of April and in May the old trouble came back, and she became almost as bad as ever. In the beginning of 1882 menstruation again ceased, and she again improved in health. This time the improvement has remained, and she is now a strong and healthy young woman, taking an active and a useful share in the work of life.

The second case of which I may speak was that of a lady's maid, *æt.* 26, sent to me by Dr. Thursfield, of Leamington. The symptoms in her case had been in existence for four years, and dated from some kind of fever, probably sub-acute rheumatism, during which she had great pelvic pain. Since that illness she had never been able to retain a situation, because she was practically disabled during her menstrual week. She had been under twelve different doctors without obtaining any relief. She had worn many pessaries, and the womb had been cut twice. The uterus was retroverted and fixed.

I removed the ovaries on July 19th, 1879, and she left the hospital on Aug. 13. She had occasional returns of menstruation till December. It returned again slightly in March, 1880, but ever since then she has seen nothing, has had no pains, and has been able to earn her living in

her original occupation. I saw her in August last in perfect health.

NOTE.—In the published reports of the discussion which followed the reading of this paper, Mr. Knowsley Thornton is made to say that in two years he had operated seventy-three times in the Samaritan Hospital without a death, this being attributable to the use of Listerism. Mr. Thornton made no such statement at the discussion, and I have been at some pains to ascertain how it appeared in the reports. I have discovered that Mr. Thornton altered the proof submitted to him by the Secretary, and inserted this statement. As to the propriety of this proceeding I will say nothing; but as I would certainly have replied to this statement, had he made it when the paper was read, I may be permitted to say something as to its relevancy as an argument. In the first place the statement is wholly misleading, as the period referred to does not include two "hospital years," but is made from the end of February, 1882, to the end of February, 1884, and just before and immediately after that period he had deaths in his hospital practice. As he excludes his private practice, we may conclude that there is something to conceal there, and that the mortality was probably heavy; yet it may be presumed that he uses Listerism in private as well as in hospital practice. Further, seventy-three cases in two years is far too small an experience from which to speak with authority so dogmatic as that assumed by Mr. Thornton whenever this question of Listerism turns up. During the same period occupied by Mr. Thornton's seventy-three cases, I removed a hundred and sixty-one ovarian and parovarian tumours, with five deaths, giving a mortality of almost exactly 3 per cent. Has Mr. Thornton as long a series as that with a mortality as low, and can he assure us that he doesn't "let his bad cases struggle up north," as Dr. Keith says he does, and as I certainly do not? I have pointed out over and over again that no argument can be maintained on the subject of Listerism from abdominal surgery unless a complete statement of the whole practice is made. Mr. Thornton has never made such a statement of his practice, whilst I make such a statement every year.—L. T.

The Gulstonian Lectures

ON

NEUROSES OF THE VISCERA.

Delivered at the Royal College of Physicians, March 14th, 1884.

By T. CLIFFORD ALLBUTT, M.A., M.D. Cantab., F.R.S.,
F.R.C.P.,

Senior Physician to the Leeds General Infirmary; Consulting Physician to the Leeds Hospital for Women and Children; and Lecturer on Medicine at the Leeds School of Medicine.

LECTURE III.—(Continued.)

DR. RALFE has kindly forwarded to me the following account of a form of renal neurosis often associated with valvular disease of the heart.

"In 1878, the late Dr. Murchison gave me the particulars of a peculiar form of neurosis attacks, which he designated as 'renal storms,' and which had frequently occurred in a patient suffering from aortic regurgitation. The attack commenced with excruciating pain over the region of the right kidney, exactly like renal colic, but there was no sickness nor retraction of testicle; the urine passed during the attack and immediately afterwards was perfectly normal (nor was there any jaundice to suggest that the pain was due to biliary calculus). After lasting some hours, the attack passed off as suddenly as it came on.

"In 1880, I saw a man, æt. 47, who applied as an out-patient at the London Hospital solely on account of a severe paroxysmal attack of pain, which, commencing at the angle of the epigastric region where it joins the right hypochondrium, passed deeply downwards into the

right lumbar region. No disease of the liver or kidney could be detected. And the urine was normal. On examining the chest, the heart was found diseased (aortic regurgitation).

"The only reference bearing on this form of neurosis or 'renal storm' is in Dr. Habershon's 'Lectures (Lectures) on Diseases of the Liver,' page 13, in speaking of the neuralgic pain sometimes met with in organic disease of the heart, and which is referred to as being deeply situated behind the first part of the duodenum: 'It is severe, almost like the pain of gall-stones, but it is without jaundice or other symptoms of calculus; it is not connected with the stomach, for it is not affected by food, but paroxysmal, and recurring sometimes with great regularity.'

I will not pursue these reasonings so far as to consider in like manner the pains of other viscera, such, for instance, as of the bladder and the rest, for the same principles apply to them all. In many cases a neurotic tendency may be aroused by a local irritation which, in robust persons, would be almost, or quite unfelt; or the neuralgia may be as "pure" as face-ache may be. Neuralgia of the rectum, however, I must not wholly pass by, for it is a definite malady, not very uncommon, and seems almost always to be "pure neuralgia." It is rarely very violent, being more of a thrusting, aching pain. It is mentioned by Anstie and other writers; I have occasionally met with it, and Dr. Myrtle made it the subject of a paper lately read to the Yorkshire Branch of the British Medical Association.

An allusion to neurotic diarrhoea, a somewhat different phase of neurosis, is again but a passing duty. Neurotic diarrhoea is a troublesome affection which, I think, is tolerably well recognised. Many persons owe the frail health of a lifetime to its recurrence, for it is sadly incurable, recurring and again recurring, uncontrolled in obstinate cases by anything less than opiates. Milder cases may be regulated by bismuth and the bromides, followed by pernitrate of iron, or sulphate of iron pills. In this disease (which must be distinguished from catarrh and from diarrhoea mucosa), the stools, though slackened, are rarely watery, and rarely contain much mucus. They may or may not be attended with pain; they are reproduced by nervous causes; they are generally worse in the earlier day, especially before breakfast, and in women they cling to the catamenial periods. Arsenic often does harm in these cases, and, indeed, can rarely be borne. The ailment occurs in both sexes, falling, perhaps, equally upon both. The diarrhoea is generally associated with other neuroses, such as migraine, cardio-vascular instabilities, and the rest. It is found at all ages, for it often begins in early adult life, and is seldom wholly removed. The pathology of the day will attribute it, no doubt, to vaso-motor disturbance, and compare it with polyuria, lacrymation, and night-sweats. It may be the homologue of pyrosis.

I would now pass on to consider the genetic affinities of the class of patients which we have discussed in these chapters. This question is more easily answered by searching among the gastralgics, as they form by far the larger number.

One fact strikes the observer very clearly in his work; and that is, the frequent association of neuroses of the vagus with certain kinds of eczema, lichen and psoriasis, with eczema and lichen chiefly. Of the alliance of gastralgia with asthma, I have already spoken; and the frequency of eczema in asthmatics is generally recognised. Now eczema and its allies are, I believe, as common in gastralgics as in asthmatics, so that there seems to be some sympathy between the vagus nerve and the cutaneous nerves. The skin-affections and the gastralgia, if concurrent in the family, may not concur in the individual, or if they do, they may not be contemporary in him, nor, if contemporary, parallel in severity. No. 245, 1883, a man, æt. 38, came to me four years before for boils; at a later date, he came to me for gastralgia of the ordinary type, without functional

stomach-disorder. For this I gave him arsenic, and cured him. Last year he came to me to tell me for the first time that he had suffered for six years from eczema on and off, and that the medicine he took for the gastralgia had removed also the eczema. On this occasion he called to ask for a renewal of the prescription, not for the gastralgia, but for the eczema. Again, No. 226, 1882, male, æt. 47, had excellent health till ten years before, which he attributed to the periodic returns of "eczema and psoriasis." Of late years he had seen but little of the eruptions, but his health was broken down by "chronic dyspepsia," for which he had been treated in vain. I found no signs of functional disorder of the stomach; the symptoms were those of ordinary gastralgia, and were cured quickly by arsenic. I find a history of skin-affections in about 18 per cent. of my cases as they stand in my notes, and I suspect this estimate, if we were to take a survey of families, would be found under the mark. As in No. 245, 1883, skin-affections, if not actually present, escape record even in the individual life, unless especially inquired into. It has been fancifully assumed, therefore, that gastralgia is an eczema of the stomach; an assumption with as little of probability as of proof. I have not, however, heard that any writer has called asthma an eczema of the lungs. Are we then led by way of cutaneous eruptions to a recognition of gout as the springs of these, of gastralgia, and of asthma? Not directly, I think, though I lean to the suspicion of some remote affinity herein. But I find that experience justifies the distinction between the eczema, lichen and psoriasis of "dartrous," and those of "gouty" habits. The distinction is partly to be seen in the histories of the patients and of their relations, and partly, though not invariably, in the characters of the eruptions themselves. In the dartrous, no doubt, these eruptions tend rather to be more acute, and more symmetrical; to moisten, to spread and to itch greatly; while, in the gouty, they tend rather to limitation, to dryness, to lack of symmetry, and to a less active tint of hyperæmia.

The dartrous diathesis of Bazin and others has, then, gastralgia among its evolutions, as the gouty may have; but the term dartrous may well be put in a subordinate place, and the term neurotic diathesis used to indicate the family. Healthy persons with dartrous eruptions, if followed home, will often turn out to belong to neurotic families. Two brothers of my acquaintance illustrate this. The one is a very healthy man, with the exception of a continual liability to eczema; the other is an asthmatic. There are other strong neurotic characters in the previous generation. But lately, again, an odd thing happened to me. A young man, seemingly very healthy, came to me for severe gastralgia of a pure type. I pressed him as to skin-eruptions, and he denied their presence in himself and in his family. Within the next six months, there came to my rooms, first, his sister, a healthy looking girl, with recent and vicious eczema around both ears; then the mother, with symmetrical moist spreading eczema of the legs; and, finally, the baby of another daughter, with eczema of the head. These successive cases were almost put down to my ominous inquiries, and, in an earlier century, I might have been burnt. There was no gout in the family, nor any suspicion of its latent presence.

But another diathesis which I find often recorded in my cases is rheumatism—rheumatism of the kind which culminates in rheumatic fever.

Miss —, æt. 17 (No. 350, 1876), had eczema capitis at age 7-8. She was then, and later, a somnambulist. After this, she had "horrible sinkings" in a forenoon for some time, and was treated for "dyspepsia." These vanished in favour of intense neuralgia of the head. In 1875 this again gave way to attacks of gastralgia, so severe, at times as to end in a faint. She was treated by several medical men of position for "dyspepsia," and

her diet corrected until it became spare and monotonous. She grew so much worse, that she was taken to Sir William Jenner, who reversed all the rules of her dietetics, fed her liberally, and gave her strychnia. She recovered in a few weeks. She called upon me for a new trouble, namely for intense neuralgia of the left orbit, often leading even to ecchymosis of the conjunctiva. Now, in this young lady's family rheumatism and rheumatic fever were well marked on the paternal side. Her father was a "delicate" man, and a martyr to rheumatism; he had had rheumatic fever more than once.

Another such case occurred in Miss —, æt. 25 (No. 480, 1882). She came of a neurotic family, and one from which phthisis had not been absent. Her consultation was in respect of gastralgia of an intense form. She had been migrainous most of her life, and she had suffered from rheumatic fever at 18 years of age.

Now do these cases, which I can strengthen by many others, lead us to make any direct tie between the rheumatico-gouty diathesis, the eczema, and the visceral neuroses? No, I think no direct tie. To turn aside for a moment, I have to set before you another affinity, which must be considered with those. Perhaps the disease most largely found in neurotic families beyond their neuroses is phthisis. In case after case I find phthisis in parents or kin. This applies to all the neuroses, not to the gastro-abdominal only. I may refer again to the last named case, No. 480, and farther to Mrs. —, æt. 35 (No. 128, 1878), who came to me for an uterine ailment. She had had four children. I found some catarrh, both uterine and vaginal, the uterus soft and the surrounding parts relaxed. She had the usual dragging aches of the pelvis, pain on jolting, tenderness to the exploring finger, and so on. She is liable to severe neuralgia, in either supra-orbital notch. Although an abstinent woman, she is sick on rising in the morning, and all her symptoms come more about her as the catamenia approach. These return every twenty days or thereabouts. She has gastralgia very often, with voluminous flatulence and pyrosis. In her family there is a strong phthisical history. She made a good amendment on sedative and tonic treatment with change of air, and she has continued to enjoy better health. Her uterine troubles vanished as she regained strength, a course of douches only being prescribed.

Mr. H., æt. 45 (No. 403, 1883), has suffered acutely from pseudo-angina, but consulted me for enteralgia arising near the umbilicus. His family history is badly phthisical.

Mrs. — (No. 414A, 1883), æt. 32, has had severe facial neuralgia, but now consults me for enteralgia and urticaria. She has had attacks of eczema. Her uterine functions present no special derangement. Her family history is very phthisical.

But I need not multiply cases which present like features merely to record that phthisis belongs to their series. This I may invite you to observe for yourselves. But, for many years, I have noted the frequent coincidence of phthisis and rheumatic fever in family trees; and I think this coincidence has been observed by others. To my mind, then, the natural group is neurosis, phthisis and acute rheumatism. But what of the gout? Rheumatism and gout are certainly akin, the two maladies appearing in the same families, and even in the same persons at different ages. Yet I think gout goes by a different route to its direct work. A pure neurosis goes hand in hand with phthisis and acute rheumatism; but pains which, like migraine, enteralgia, sciatica and so forth, may, in such association, be of the purest type, may, in other instances, be caused by the poison of gout, and thus should be put into a separate class, with the eczema and psoriasis of gout, which again are not "dartrous." In the one class, the neuralgias depend upon some congenital defect of nutrition, affecting the nervous apparatus itself; the thing is essential: in the other

class, the nervous apparatus, originally healthy enough, and even vigorous, is angered by a circulating poison. Yet is there not some alliance beyond this? Is there not some remoter pathological kinship, unexplained by the humoral theory? Yes, I believe there is. I believe that, farther back, there is some community of nature between the gouty and the neurotic habits; and to this we may ascend when we track out those phenomena which suggest that gout is itself originally a neurosis. Although there is, then, no cross alliance between neurosis, phthisis and gout, yet one may trace the history of gout upwards to a point of union with a divergent stock, which, two, three, or four generations back, had branched off into the tuberculo-neurotic. In such cases—and I have notes of several of them—anti-gouty remedies are of no use whatever. Finally, there is another form of neurosis of gouty origin, for the relief of which antigouty medication is useless; and that is seen in skin affections, or neuralgias which had been directly aroused by the active presence of gout, but which were left stranded after the gouty humours had ebbed. Flotsam and jetsam of this kind are common in practice, and in such cases we do ill to run upon specific medication. A hemiplegia may remain, forgotten as it were, when the cerebral centre has healed; and will persist, perhaps, unless driven off by faradism. A syphilitic ulcer may remain after the syphilitic state has been wholly counteracted by the usual remedies, and decline to heal until some more general treatment is taken up. In like manner, an eczema or a neuralgia may be set up by gout, and this, as it ceases to be active, leaves behind it some altered or lowered state of tissues, which no longer acknowledges the first disturber of the peace, but lies in a simpler dejection of its own. We must try the specific measures; but, if these fail, we must not therefore assume that our surmises as to the original cause of the ailment were false. These are the remnants which are sometimes suddenly routed by a blister or an acupuncture. Urticaria is not an uncommon addition to other neuroses, as is well known; and I forbear to record many of my cases in which it was found together with visceral neuroses. One I have cited above, under No. 414A, 1883. Zona is, perhaps, never found with a visceral neurosis, unless there has been some cerebro-spinal nerve-disturbance therewith. Mrs. W., æt. 66 (No. 546, 1881), came to me for general and nervous debility. She told me she had suffered repeatedly from angina pectoris (whether the true angina or not, I cannot say) but that with the last attack there broke out a violent crop of shingles, after which the angina returned no more.

I saw a very remarkable series of this kind in a patient of Dr. Steele, of Morley. She was a woman somewhat beyond middle life, whose whole temperament and history afforded a good picture of the tougher kind of neurotic. When I saw her, the neuralgia of the viscera had extended to the cerebro-spinal system, and so involved the nerves of the left arm that a crop of zonal vesicles occupied almost the whole length of the ulnar aspect of it, from shoulder to wrist. There was no gouty history in the case.

And now, gentlemen, my limits warn me that if I am to comment upon the treatment of visceral neuroses I must hasten to that end. Although the basis of all therapeutics must be a clear diagnosis, yet, on the other hand, the most elaborate diagnoses are but laborious idleness if not made the means of cure. We cry out with the child in La Fontaine.

"Eh! mon ami, tire moi de danger;
Tu feras, après, ta harangue!"

The beginning of all successful treatment must be to convince the patient of the true nature of his malady. Now, your neurotic is one who has no reserve. This want is probably due to a congenital instability of nerve, showing itself as waste, so ceaseless, that the reserve once dissipated is never re-accumulated. This reserve may have been spent in beneficent activities; or it may

have been dissipated in fidgets, fretfulness, or shrewdness; in sleeplessness, in anxiousness, or in pain, according to the quality of the person. We are disposed to forget that the silent work of nutrition uses more force perhaps than many people expend in their neuromuscular life; hence the early failure of the digestive resources in neurotics, hence the fall of the balance of nutrition below the needs even of a controlled expenditure. We know that good nutrition is a chief condition of steady work, good temper, and self-control; we know, too, that to trade daily only upon the supplies of the day is to court collapse; we must have more brain, more spinal marrow, more liver, more kidney than we want for the day. We must have stored-up force, partly for greater occasions, partly to secure the equable running of our machinery. A neurotic person is an engine with a light fly-wheel and a small furnace, whose work, therefore, is fitful and unsafe. In the early life of neurotic subjects, especially, we must husband the reserve, we must control expenditure, and cherish nutrition. To heap up again a wasted reserve is always a long and laborious task, and, as years go on, becomes harder and harder. Many people, even when under middle age, never wholly replace their reserve if wasted, let us say, by acute disease; so that this factor of steadfastness and safety is never wholly replaced. In an exhausted neurotic, the secret of treatment, therefore, is—by food, fresh air, exercise and happiness—to lift up your patient from the invalid couch, not for the day or for the month only, but to teach him so to manage expenditure and so to promote nutrition as to replace his capital. He must establish in himself the habit of a cool temper and rhythmical work, and root out the habit of wasting volumes of good worry upon forecasts of events which never happen, and on visions of unsubstantial things. Unhappily, however, nine neuralgics out of ten are possessed by the belief that they are dyspeptics, and that the cure of their malady is to be found in some farther defalcation of their diet, in some new arrangement of it, or in the use of some new combination of stomachics. Once convince them that the stomach is the seat of neuralgia, and that any pain caused by food is as accidental as is the increase of pain in *tic-douloureux* during the act of mastication; once let them realise that, so far from waving their dishes aside, like the physicians of Sancho Panza, you would rather prompt them to indulge as liberally as their impaired forces will permit; once persuade them to throw all their alteratives, their pepaines and their mineral waters to the dogs, and your battle is half won. I cannot read the lives of men like De Quincey or Carlyle without suspecting that a timely or untimely course of Fowler's solution would probably have deprived us of the letters of Mrs. Carlyle and of the "Confessions of an Opium-Eater." Assuredly a gastralgic can no more eat a good dinner than he can walk a league; but by careful advances, and the repetition of small light, highly nutritious and social meals, he will eat his way upwards. The first dread of food over he will begin to digest *con amore*, and he may perhaps be helped to this end by the aid of pepaine, though my patients seem to do nearly as well without it. In severe cases, the warmth of bed for a few days, or even for two or three weeks, is of great value; economy of work and economy of heat is thus secured. Many a case of neuralgia which had resisted all medicines has been cured by a course of bed alone. The very common association of cold extremities with gastralgia, and indeed, the oft noted influence of chilled feet in setting up an attack, is an indication of the need for equable warmth. Dwindled meals fail to supply both heat and nutrition; and, in extreme cases, the Weir-Mitchell system, by stimulating nutrition, may re-open the fountains of warmth and vigour. The visceral neuroses again, like the rest, are aggravated by cares and sorrows, and by depressing conditions of life. Release from toils and worries, and a change of air and

scene, take a leading part in the cure. Gastralgia as a rule do better inland than at the seaside. At the sea they are apt to become irritable or sleepless; but these ill effects are lost on withdrawing a mile or two inland. On the other hand, the high mountains are not favourable to neurotics; they fare ill at St. Moritz and Davos. Milder upland airs like Malvern or the Sussex Downs—dry sunny slopes a little remote from the sea—suit them best. For how many patients can we write the prescription—to take two months holiday, to withdraw from all toil and care, and to live in good company on refined and delicate food? And yet how potent are such means when all else may fail! Mr. Teale and myself tried in vain to cure a clever, impulsive, and over-worked Leeds clothier of gastralgia, mixed with some actual dyspepsia, until we sent him on a sea-voyage. His own words on his return were: "After a few days, bile could not live in my stomach, and my tongue was as clean as if I had manufactured it myself." The only things necessarily to be forbidden are tea, coffee, tobacco, and the stronger meats, such as beef. Over many persons thus susceptible, tea has an evil power; it retards the pulse, and creates the horrible empty exhausted feeling, which seems as hard to bear as very pain. Alcohol I do not encourage in neurotics; that there is a little occasional help in it, I admit; but, on the whole, alcohol, drawing as it does upon the reserve fund which we wish to protect, is better away from persons who may learn to take it rather as a dram than as a small addition to meals; this error, in them, is a radical one. A like danger may follow the use of morphia, but severe cases cannot be treated without it. The repeated attacks so exhaust the patient, that it is only by economising his forces with warmth, rest, and morphia that he can retain any for the absorption of his food. Morphia may be given fractionally in ordinary mixtures, or periodically in larger doses, but in either case the remedy should be kept under the control of the doctor; in many cases it is even well to keep the patient in ignorance of the agent. For this reason, I often order Dover's powder in pills, in order that the compound may not be recognised in the prescription as opium. Of other drugs, arsenic in gastralgia takes by far the chief place; indeed, it is hard to say how gastralgia was cured before the time of its introduction by Dr. Leared. Yet, even now, its power is not sufficiently well known, for, on turning to Dr. Ross's work on the "Nervous System," which I suppose to be the best in our language, I find no mention of arsenic as a remedy for gastralgia; and Dr. Sponder's rules for the use of the drug are too timid. Yet, after all, with soft nutritious food, warmth, rest, and lenitive or narcotic doses of opium, many cases of gastralgia still resist treatment. Oddly enough, a repetition of small blisters to the epigastrium may then be of service; and of other drugs, quinine, boldly pushed on, with belladonna, form a valuable combination; and so, again, do quinine and bromide of ammonium dissolved in hydrobromic acid. The infusion of the *Prunus Virginiana* makes an excellent vehicle for such mixtures. Not uncommonly, gastralgia is a product of malaria. Of this nature I have two cases before me, and in one of them very large doses of quinine cured a most intractable gastralgia, which had resisted all other measures. Luckily, I knew my friend had travelled in the East and had had ague there. The silver salts, again, are of undoubted use; with nitrate of silver I cured one case which had defied all my previous measures. Of manganese I have no experience. Of iron, I speak last; it has only been of much use to me in a few cases, for I do not, in fact, observe that anæmia, apart from the general lowering of all nutrition, has been so marked a feature in my cases of gastralgia as many authors definitely assert of their own. Where any distinct anæmia exists, iron, of course, is indicated, and often works a cure. Phosphorus is not so useful in gastralgia as its kinship to arsenic would lead us to expect; but the pharmaceuti-

cal compounds of the hypophosphites now sold do, by virtue of some one or more of their constituents, seem to answer well. As the stomach gains vigour, cod-liver oil should be added to the dietary, it will help on nutrition and forward recovery. In a word, arsenic and quinine are the only specifics; and the rest of the treatment may be summed up in rest, sedation, nutrition, and tonics. Some gastralgics find that alkalies give them a temporary relief from pain, even in cases of neurotic and periodic type. It is not generally so, however, and the practice is not a sound one.

When we leave the vagus nerve, when we leave asthma, angina pectoris, and gastralgia, we find that the specific powers of arsenic are no longer so trustworthy. In enteralgia it may have some value, but far less than in gastralgia; in enteralgia, quinine and belladonna seem best to forward restoration, though arsenic is, even here, by no means to be despised. In all visceral neuroses a most careful search must be made for any kind of peripheral irritation, and such irritation soothed and its causes averted. Of the infinite pains, moral and dietetic, which are needed for vomiting cases, I need not speak, for the management of them is sufficiently well known. The only unfamiliar drug which I can recommend for these cases is the walnut-spirit sold by Messrs. Corbyn and others; this medicine, which was indicated some time ago in the *Practitioner*, I have certainly found very useful in cases of neurotic vomiting. It must also be remembered that gastralgic vomiting is spasmodic asthma of the stomach, and that a few whiffs of chloroform, or a little subcutaneous morphia, may cut the one short as well as the other.

Mr. President and gentlemen, I must not detain you longer. Happily free as I am from neuroses in general, yet a sinking at the heart has possessed me many a time as I wrote and then read the lectures I have ventured to present to you. How slender is the offering none knows better than I. Once I comforted myself with the thought that the late Dr. Symonds did not think the subject of Headache too trivial for your thoughts; but again I reflected how much the more must be the talent of the speaker the less striking the subject, and how great the interval between him and me. That I have said nothing new to you I am painfully aware; that my words may not have fallen below the authority of this chair is my single hope.

AN IMPROVED FORM OF NASAL INHALING TUBE.

THIS instrument consists of a mould of the tip and alæ of the nose, the base or floor of which fits accurately over the entrance to the nostrils. Upon this floor are two perforated conical projections for insertion into the nostrils, and these communicate through a chamber below, by means of an indiarubber tube, with an inhaler. The advantages of this method of inhalation are: First, that medicated vapours may be thoroughly applied to the whole cavity of the nose and upper portion of the pharynx, as well as to the lower portion of the respiratory tract; secondly, that by this means the normal process of respiration is insured, viz., inspiration through the nose, instead of through the mouth, and consequently the act is more complete and less fatiguing to the patient; also, the enforced act of breathing in through the nose and out through the mouth is an aid in overcoming the habit of oral breathing, to which most patients suffering from nasal catarrh are addicted.

The application of medicated vapours to the nasal tract has been carried on as a separate method of inhalation, and in a very limited manner. Sometimes this is effected by inhaling vapour through the mouth and endeavouring to blow it through the nose, the perfect accomplishment of which depends upon the skill of the individual. More often the patient breathes steam from an inhaler through one nostril, while th-

opposite one is closed by the finger, through an olive-shaped nozzle, made generally of soft rubber, which is so compressible that it is apt to become blocked up. Comparatively little vapour passes into the nose by this means, and still less beyond, while the patient in stooping over the inhaling apparatus contracts the chest, and approximates the process to that of mere smelling instead of full inspiration.

The principle intended to be carried out by means of the instrument before us is, then, to do away with this division of nasal and oral breathing into two separate acts, and substitute normal, deep inspiration through its proper channel.

The instrument, which has been made from Dr. W. Mac-Neil Whistler's design by Messrs. Maw, Son, and Thompson, of London, is of vulcanite. It is light, smooth and unirritating, and is easily cleaned. The india-rubber communicating tube, which is sufficiently long to allow of proper expansion of the chest, may be adapted to various forms of inhalers.

GENEVA is at present threatened with a severe epidemic of typhus and typhoid. One-third of the entire mortality during last week was due to this cause.

St. John Ambulance Association.—With the concurrence of the Principal Medical Officer, Devonport Garrison, classes for the troops have recently been held in connection with the St. John Ambulance Association, attended by officers, non-commissioned officers, and men of all ranks. Surgeon W. B. Allin, M.B., A.M.D., acted as lecturer, and Surgeon-major Alex. Turner, A.M.D., as examiner. The latter has forwarded to St. John's Gate a most eulogistic report on the excellence of the knowledge displayed, especially as regards practical work, and the first treatment of the wounded. This is shown by the fact that the whole of the candidates for examination, which took place in the presence of the Principal Medical Officer, are recommended for certificates, the members being as follows:—Royal Marines, 6; 2nd Battalion South Lancashire Regiment, 22; 2nd Battalion Highland Light Infantry, 34; and Commissariat and Transport Corps, 12. Among the officers are Lt.-Col. S. J. Graham, C. B.; Major H. J. L. Norcock; Captain R. H. Hall; Lieut. E. A. Snow, and Asst. Commissary General J. A. Scott.

Clinical Records.

ST. BARTHOLOMEW'S HOSPITAL.

Cases of Osteotomy, with Remarks. (a)

By HOWARD MARSH, F.R.C.S.,

Assistant-Surg. to, and Lecturer on Anatomy at, St. Bartholomew's Hospital.

ALTHOUGH the evidence to establish it is complete, there are many who are deterred from accepting a new position because they have never quite dismissed their surprise at finding that what they had not suspected is yet true. Osteotomy is a case in point. Experience has shown that this operation is safe beyond all previous expectation. Yet many surgeons never use it, although the necessity for osteotomy, in some cases, is as clear as the necessity of tenotomy in others. But with some surgeons the surprise they have felt at the safety of this new proceeding has had another, and contrary effect, and has led them to practise it with too little discrimination. It is, no doubt, generally safe to divide the tibia for rickety deformity, but there are few cases in which such an operation is necessary, at least, in children under three or four; for, with subsequent growth, the deformity, if the child is kept off his feet, and fed with meat and milk, and is ordered cod-liver oil, will gradually disappear. Nor is osteotomy required, except for the more severe forms of knock-knee. Discussion, and further experience, will lead to the adoption of the proper medium between these extremes in respect to this method of treatment. The following cases are briefly reported as examples of the application of the operation to conditions which could not have otherwise been remedied. They also present some further points of interest.

CASE I.—Mary P., *æt.* 17, had had hip-disease in childhood, and her femur had become ankylosed at a right angle with the trunk. The greater trochanter lay an inch above Nelaton's line; but a short neck could be distinctly felt. As no movement, during examination under ether, could be felt between the femur and the pelvis, an incision was made, about three quarters of an inch long, just above the trochanter, and the finger was introduced to ascertain the dimensions and axis of the neck. A chisel was then used to divide the bone to about half its thickness: the remainder gave way with the exercise of very moderate force. Lister's dressings were used. The patient was confined to her back, by means of a Liston's long splint applied to the sound side. The limb, with the knee straight, was supported, in its deformed position, on a rest, and a weight acting in the long axis of the femur, and running over a raised pulley, was attached to the foot. There was no rise of temperature after the operation, and no suppuration. The wound healed in about a fortnight. Under the action of the weight the limb gradually passed into a position of complete extension, so as to be in a line with the trunk; the pulley being gradually lowered so that the weight always acted in the long axis of the femur. At the end of two months the patient was discharged, wearing a Thomas's splint. There was movement through three or four degrees, between the femur and the pelvis. I should have preferred bony ankylosis. With bony ankylosis no return of deformity can occur but with ligamentous union there is a tendency for the limb to become again flexed upon the trunk. The method by which the limb is brought down in cases in which the femur has been divided for deformity of the hip is important. If the limb is forcibly extended at the time there is considerable danger that the femur will slip upwards and backwards on the dorsum ilii, a movement of the bone which not only shortens the limb, but, by altering the line of gravity of the trunk in relation to the femur, produces lordosis. But by using weight-extension, acting always in the long axis of the thigh, the limb may be fully extended without any risk of tilting up the femur. This method, besides, is much more comfortable to the patient, as the limb is kept throughout in an unconstrained position. It was striking to see how easily the muscles and ligaments in front of the joint yielded to continuous extension. They gave way here, as they do when the weight is used in the ordinary treatment of hip-disease, as if they certainly had undergone no structural shortening.

(a) Read before the West London Medico-Chirurgical Society.

CASE II.—J. D., æt. 42, had pyæmia after a poisoned wound. In the course of this attack his ankle suppurated, and was left firmly ankylosed, apparently by bone, in a position of marked equinus. He came to the hospital, nine months afterwards, complaining that he could not get his heel to the ground, nor walk on the limb, any attempt to bear weight on the ball of the foot causing him severe pain. When he was under ether I found the ankle-joint fixed, though the tendo-Achillis was not tight. It was evident, therefore, that no change in the position of the foot could be produced by tenotomy. Under these circumstances I introduced a narrow chisel, through an incision over the front of the ankle, just outside the common extensor tendons, and so far divided the union between the tibia and astragalus that these bones could be moved on each other. There was no difficulty in finding the interval between them. As the tendo-Achillis became tight when the foot was flexed on the leg, it was divided; and the foot was fixed on a splint well within a right angle with the tibia. The wound healed favourably; and the temperature never rose above 100° Fahr. For some nights the patient was in considerable pain, and hypodermic injections of morphia were given. In six weeks he could stand on the limb. He was discharged nine weeks after his admission. I saw him again three months later. He then said he could walk freely, and without pain, on his heel, and he illustrated this by hopping upon the foot. Mr. Willett and Mr. Baker had previously had cases similar to this one, and the same method of treatment had yielded good results in their hands.

Ankylosis of the ankle-joint is but seldom met with, but when it does occur it will be found that if, as is very likely to be the case, the foot is in any degree of equinus, the patient will walk in a very awkward manner. He may tread on the ball of the foot with the knee bent to accommodate the limb to the amount of the equinus, but his gait will be so unsteady that he will probably elect to walk on his heel. This, however, he can only do by keeping the limb in advance of its fellow; a method of progression that is both slow and labourous. Patients walk much more easily and quickly on the limb after a Syme's amputation than, so far as I have seen, those do whose ankle-joint is fixed, unless it is placed well within a right angle. This point should be borne in mind during treatment.

CASE III.—R. C., a sailor, æt. 30, was admitted with his right arm crippled by an unreduced dislocation of the head of the radius backwards and outwards. Pronation and supination were entirely lost; flexion and extension were very limited and painful. On endeavouring to increase movement by forcible manipulation under ether, I found nothing could be gained by this means, as the radius was firmly locked against the humerus. I therefore removed the head of the radius. In doing this, care was required to avoid injury of the posterior interosseous nerve, as it ran behind the bone beneath the supinator brevis. On dividing the neck of the radius, I found it had been fractured, and that the callus thrown out around the fragments had acted so as firmly to lock the joint. The case made favourable progress, and when the patient left the hospital, at the end of five weeks, he had regained free flexion and extension, and, to a considerable degree, pronation and supination, and movement at the joint was free from pain. This case deserves to be recorded as an instance in which so rare an accident as fracture of the neck of the radius was proved to have occurred.

CASE IV.—In July, I performed MacEwan's operation for the relief of knock-knee in R. T., æt. 7, in whom, when the condyles of the femora were in contact, the malleoli, were separated by a distance of eleven inches. This case is related in order that the complication of hæmorrhage from the anastomotica magna may be alluded to. As to the right limb, nothing need be said. On the left side, the incision was made in the usual situation, that is, half way between the tendon of the adductor magnus, and a line drawn upward from the inner border of the patella, and an inch and a half above the upper margin of this bone. Somewhat free hæmorrhage occurred at the moment, but it soon ceased. The bone was very soft, and gave way after a very limited use of the chisel. The same evening such severe bleeding occurred that Mr. Brinton, the house-surgeon, and others who saw the case with him, were afraid the popliteal artery was wounded. The tibials, however, were pulsating naturally. Bleeding was easily stopped by

a compress and bandage. All went on well for the next seven days, when another hæmorrhage, quite as copious as the first, took place; but this also was readily controlled. I now examined the wound. On enlarging it, I came at once on the anastomotica magna, in the side of which an oval opening was plainly seen, from which blood freely escaped. On completely dividing the vessel, and tying its two ends, bleeding ceased, and never returned. The child made a good, though slow recovery. The fact that two large hæmorrhages, separated by an interval of a week, occurred from a vessel of the size of the anastomotica magna is important. It conveys a caution against tying any principal artery, the closure of which may be disastrous to parts beyond, until every safe means has been taken to ascertain the exact source from which bleeding is derived.

Transactions of Societies.

ACADEMY OF MEDICINE IN IRELAND.

SURGICAL SECTION.

A MEETING of the Surgical Section was held at the College of Surgeons on Friday evening, March 7th, Mr. COLLES, in the Chair.

Mr. STOKES, hon. sec., read the minutes, which were confirmed.

FOREIGN BODIES IN THE KNEE-JOINT.

Sir GEORGE PORTER read a paper on the subject of foreign bodies or loose cartilages in the knee-joint, the interest of which to the practical surgeon he pointed out; first, as regards their presence in an articulation, which, in reference to size and utility in locomotion, was the most important in the body; and secondly, owing to the excruciating pain and often recurring attacks of inflammation their presence, so frequently produced by getting locked between the articulating surfaces of the bones, rendering the life of the patient most miserable, and preventing him from following his usual avocations or indulging in any form of active exercise. He then gave a *resumé* of how these bodies are formed in the knee-joint, stating that they varied in number, size, and colour. Having mentioned the symptoms and treatment, he described two cases of foreign bodies in the knee-joint that he had recently cured by the direct incision, with full antiseptic precautions. The first case was that of a soldier of the 5th Dragoon Guards, who suffered from a loose cartilage for the last four months. The second was that of an eminent Dublin gunsmith, who had had a large pistol bullet lodged within his knee-joint for the last thirteen years. Both cases were most successful. Sir George Porter paid a tribute to the value of antiseptic surgery, observing, "These two cases I consider might be received with interest by the Academy, and I think are additional proofs, if such were required, of the great advantages of antiseptic surgery. In my student days a wound of the knee-joint with escape of synovia was often followed by amputation or death. Now, without fear, we cut into the knee-joint under the carbolic spray and other antiseptic means, thus stamping on Listerism the verdict of almost universal success."

The CHAIRMAN mentioned that the late Mr. Alcock, in his work on surgical experience in the Peninsular campaign, recorded several cases of balls penetrating the knee-joint having been successfully treated.

Mr. THOMSON welcomed Sir George Porter to the ranks of the advocates of Listerism. Concerning Mr. Alcock's experience, it was not pretended that wounds of the knee-joint did not get well before Listerism was established. Perhaps they got well in spite of the surgery of the day. But it was contended that under other conditions the uniform success was not had that was obtained under Listerism.

Mr. STOKES emphasised the surgical importance of the cases Sir George Porter had brought under notice. The second case was of special importance as confirming the statement of Sir Wm. M'Cormack, in a lecture in New York, concerning the principle long neglected by military surgeons of not interfering immediately with gunshot injury involving any large articulations. His vast experience in two campaigns enabled him to lay it down as far the best surgery not to probe the wound too freely, and make diligent search for foreign bodies immediately on the

reception of injury, but to wait until matters got into a quiescent state, and then, if the foreign body became troublesome, cut down upon it. The two cases also showed what great things could be done by following the Listerian method.

Mr. ORMSBY having been present at one of the operations bore testimony to the difficulty experienced in fixing the loose cartilage in the case of the soldier. He suggested a discussion of the relative merits of the direct and indirect incision for the removal of foreign bodies or loose cartilages in the knee-joint. The indirect or subcutaneous incision was formerly preferred as the safest, and least likely to be followed by diffuse suppuration of the knee-joint. In the last case, in which he saw direct incision performed without antiseptic precautions, diffuse suppuration of the joint ensued, ultimately necessitating amputation of the thigh. Under the Listerian method direct incision could be performed with small risk, as Sir George Porter's two satisfactory cases proved.

Mr. BENNETT while appreciating antiseptic surgery cautioned practitioners against being too ready in relying on its efficacy, to open the knee-joint or any other. He protested against the universal acceptance of Listerian treatment; for instance, in a case where the presence of the foreign body was the result of rheumatic arthritis.

Mr. MILES thought Listerian enthusiasts took too much credit for the success of that treatment.

Sir GEORGE PORTER in reply agreed with Mr. Bennett that a rheumatic case should not be interfered with.

PISTOL WOUND OF THE CEREBELLUM.

Mr. THOMSON read a paper on pistol wound of the cerebellum. The subject was a detective officer shot in an affray. There were two wounds, one in the occipital bone, about an inch to the right of and an inch below the occipital protuberance; the second in the left arm. The apex of a bullet was found on the right margin of the bone wound in the skull. The right lobe of the cerebellum, corresponding to the wound, was crushed by fragments of bone and lead to the depth of half-an-inch. There was a clot between the right parietal and the dura mater, and on the inner surface of the same bone the mark of impact of lead. The base of the bullet could not be found for some time, and it was then discovered embedded in its own depth only in the brain substance of the *left* hemisphere at the anterior and inferior portion. The fragment had evidently passed between the dura mater and the vault of the skull from right to left. A similar case is noted by Larry. The person charged only fired one shot, so that the second was from some other pistol. Mr. Thomson discussed the questions:—(1) Could a person standing in the position of the assailant have inflicted the wound on the back of deceased's head? (2) Could a person with such a wound of the cerebellum have advanced upon his assailant, as it was proved deceased did after the first shot was fired? (3) Is a wound of the cerebellum immediately fatal? He believed the wound could have been inflicted; that it was possible that a person so struck could advance, though in a "drunken" manner; and that such wounds were not necessarily fatal.

Mr. BENNETT called attention to two points, first, that of a bullet being cleft upon the bone, and so misleading in the investigation; and secondly, the fact that the cerebellum could be wounded superficially, and it might be deeply, without phenomenon. He mentioned the case of a sailor, who, whilst on deck, was struck by a falling iron, 20 or 30 lbs. weight, which grazed the top of his head, and the wound, $1\frac{1}{2}$ inches long, overlay the cerebellum. When admitted to Sir P. Dun's Hospital the man presented no cerebral symptoms. There was considerable depression of the inner table, and some loss of bone, it being gouged out and the brain substance escaped. The wound was treated on the simplest principle, and in three weeks it closed sufficiently to enable the man to leave hospital.

Dr. HENRY KENNEDY said it was not the wound of the brain, but the hemorrhage that did the mischief.

Mr. LENTAGNE corroborated Mr. Thomson's account of the post-mortem examination, at which he was present, but differed with him as to the bullet having travelled between the dura mater, there being no lead streak along the supposed track. The cases established that the man might have received the head wound first; but from the position of the parties he thought it more probable the other was first.

Dr. M'ARDLE mentioned two cases showing that the cere-

bellum cannot be extensively injured without co-ordination being impaired.

Mr. ORMSBY saw no difficulty in believing that the bullet took the course indicated by Mr. Thomson. A quay labourer who fell into the hold of a ship walked home, and next morning went to an hospital complaining of a severe pain in his head. Not satisfied with the attention he received he became excited, and abused the hospital officials, who thought he was drunk. Thence he went to the Meath Hospital and was admitted. On being put to bed he became unconscious and all the symptoms of brain compression were apparent. He never rallied, and died 72 hours after the fall. A post-mortem examination revealed an extensive fracture of the skull with laceration of the cerebrium and cerebellum.

Mr. CORLEY arrived at the conclusion that no condition of the brain from injury or disease would indicate what capacity the patient had, mental or physical, before death. A man, through whose head a bullet passed, felt as if he got a cut of a whip.

Dr. HUSTON mentioned that in dissecting a subject he found the whole of one lateral lobe of the cerebellum degenerated, being almost entirely composed of a cyst, and on inquiring ascertained that the only symptoms exhibited were moroseness of temper.

Mr. THOMSON said the cases mentioned by Messrs. Bennett, Ormsby, and Corley, proved that severe injury to the cerebellum might be present without producing the want of co-ordination that might be expected. As to the course of the bullet, he could not accept Mr. Lentaigne's objection. At one point on the inner side of the vault of the skull there was a bullet stain between the dura mater and the skull. He had avoided any expression of opinion from prudential reasons beyond discussing the abstract questions raised on medico-legal grounds. If the charge of murder was to be sustained, the accused must have fired the first shot. The deceased had a second wound on the arm, which was not mortal.

The Section then adjourned.

THE WEST LONDON MEDICO-CHIRURGICAL SOCIETY.

At the ordinary monthly meeting held on Friday, 7th March,

The President (Dr. THUDICHUM), in the chair,

Mr. HAROLD HENDLEY, in conjunction with Mr. R. F. BENHAM, read the following paper:—

A CASE OF POISONING BY AMMONIATED AND RED OXIDE OF MERCURY.

This is the case of a female, æt. 20, who in despair, swallowed 90 grains of each of white and red precipitate powder for the purpose of poisoning herself, being pregnant at the time. The patient was first under the care of Mr. Benham, but eventually she was admitted to the West London Hospital for the reasons stated hereafter. Hence the following account is by Mr. Benham up to the date of the patient's admittance into the hospital. About mid-day on Sunday, 5th August last, I was sent for to see this patient, having been informed that she had some hours previously taken a large quantity of poison. Shortly after taking the poison the patient was seized with burning pains in the throat and chest, and gripping pains in the stomach, causing her to vomit most violently, and in addition, about an hour afterwards, she began to have diarrhoea, which gradually increased. In this condition she remained for about four hours, and feeling that she was becoming weaker and weaker, and apparently losing her senses, she was obliged to lie down on the ground, having also cramping pains in the abdomen and lower limbs. On my arrival I found the extremities and head were cold, the face and forehead being pale and bathed in a cold perspiration, the eyes were glassy, and the pupils were only slightly sensitive to light, the pulse was small, weak, and 60°, and at times imperceptible, respiration laboured and 16, temperature 97°, surface of the tongue and mucous membrane of the cheeks around were swollen and cream-coloured. She appeared to be in a semi-collapsed condition, but was tolerably conscious and was able to answer questions. She complained of a burning sensation in the throat and chest (gullet), of severe purging pains over the abdomen, pains of

cramp in both extremities, was vomiting at short intervals a thick ropy mucus-looking fluid, and was passing by bowel mucus tinged with blood. The abdomen presented the characteristic appearances of advanced pregnancy, the foetal heart could be distinctly recognised, the os uteri was closed, and from the position of the foetus she was presumably about six and a-half months pregnant. Directly after ascertaining the nature of the poison I administered a glass of milk containing two eggs, which was swallowed with difficulty, and it returned immediately. I then placed her in bed, applied hot bottles to the feet, hot clothes to the head and abdomen, and fed her with teaspoonfuls of milk and egg mixture with some brandy, but she only retained it for two or three minutes. Seeing that she was becoming rapidly more collapsed, I injected first one drachm of ether hypodermically, and then one third grain of morphia. This seemed to stimulate the heart's action, but the cramping pains were increased, (most probably due to the less collapsed condition). I continued with the hot water applications, and in addition administered an alkaline and stimulating mixture, containing also prussic acid. The excessive vomiting now somewhat abated, so that she was able to retain the milk and egg for about fifteen minutes. I endeavoured to administer a nutrient enema, but it was immediately returned. Two hours after I gave another injection of each of the ether and morphia. Her symptoms gradually improved for the next two days, with the exception of a considerable ulceration of the tongue and mouth, with salivation; but after that time the urine became scanty, containing a large amount of albumen and casts. The quantity, however, secreted gradually diminished, so much so, that from the 4th to the 8th day after taking the poison, she passed only about 30 ounces, the ratio being 12, 8, 5, 3, 2 ounces, the latter being the amount secreted on the 8th day; it was mucus-like in appearance, and coagulated on boiling. A catheter was passed on several occasions. In addition to the suppression of urine, she complained of slight abdominal pains, and on making an examination I found the os somewhat dilated and hard, as if assuming the first stage of labour. Believing the patient to be on the verge of having a miscarriage, that the suppression of urine was an alarming symptom, and that it was advisable to give warm baths, which could not, however, be procured at the patient's house, I accordingly had her removed to the West London Hospital. I made several analyses, by means of the amalgam test, of the saliva, urine, and motions, and in each case there were various shades on the surfaces of the sheet-copper according to the quantity of mercury. On admission to the West London Hospital on the 11th August, where the patient was under the care of Mr. Hendley, she was suffering from suppression of urine, the tongue thickly coated with fur, fissured but moist, mouth, gums, lips, and lower part of tongue covered with small ulcers, breath fetid, skin dry and somewhat quickened, temperature 100° F., pulse rather fast, regular and fairly full. Breasts large and swollen, no pain in epigastrium. As she was admitted late at night and seemed comfortable, nothing was done for her till the morning. Early on the morning of the 12th one ounce of urine was drawn off, looking like watery mucus. A vapour bath was given, lasting twenty minutes, and under its influence the patient perspired most freely, and was considerably relieved, also 5j. of pulv. jalapæ co., beef tea diet, and gargar. pot. chlor., for mouth. In the evening a second bath was given with like effect, and one and a-half ounces of urine was drawn off of the same character as first. At 3 a.m., on the 13th, Mr. Hendley was called hurriedly, and found the patient in labour, child presenting at the perineum, and was born in a few minutes, but in spite of all efforts to keep it alive it died in about a quarter of an hour. It gave the appearance of a six months' foetus. Two or three hours after the birth of the child the patient passed three ounces of water and there was no further trouble with it. There was very little hæmorrhage and the patient did well till the 16th, when a rash appeared upon the arms in isolated, raised and vivid red patches, temp. 98°, and all through it was little above that. On the 19th the rash became confluent over face, arms, and thighs, and patchy on chest. The patient was sick several times during the day, but she had no sore throat, although her tongue was badly ulcerated. She was put on pot. iod. gra. v. with a saline mixture. On the 20th, the tongue became cleaner, but there was a great deal of

sickness during the day with pain in the back and head. On the 21st, the arms desquamated and, at the same time, a peculiar mottled appearance presented itself upon the chest. On the 23rd, sickness ceased, the rash became confluent on the chest, while retaining its vivid red character. On the 26th, the rash was fading away on chest, gums firm, desquamation of the face and arms still going on. There was no trouble with the breasts all through, and no signs of milk externally, it was not drawn off, and seemed to become absorbed in a few days. She was discharged quite well on the 30th August. *Remarks.*—Several of the staff who saw the case during the time of the rash thought it very like that of scarlet fever. The rapid disappearance of the milk would lead one to suppose that the mercury exerted its well known absorbent influence in this direction, and it is well worthy of remark that the serious symptoms disappeared in a marvellous manner after the birth of the child, in fact, before the rash appeared it seemed as though the child had taken the whole of the poison away with it, and thereby saved its mother.

Dr. THUDICHUM communicated

TWO FATAL CASES OF PERITONITIS SIMULATING POISONING.

The first case had occurred in the practice of Mr. T. Wood Hill, who consulted Dr. Thudichum about it. It was that of a girl, æt. 7, who died in less than 36 hours after the beginning of the symptoms. There was a coroner's inquest, and at the post-mortem examination of the body of the child the effects of acute peritonitis were found. By a minute search only was the cause of the peritonitis discovered to be a perforation of the intestine at the junction of the cæcum and vermiform appendage, a perforation so minute as just to admit the passage of a crow-quill. It terminated on the peritoneal end between a cluster of enlarged, but not otherwise diseased, glands; there was no ulceration in the cavity of the cæcum. It could not be decided whether a foreign body, such as a fish bone or bristle had given rise to the perforation, or whether it arose from perityphlitis. The second case which Dr. Thudichum related was that of a young lady, æt. 16, who exhibited most of the symptoms of acute poisoning by irritants. There was a short remission of the symptoms, after which the conditions relapsed and terminated fatally in 24 hours, with vomitus cruentus and collapse. The post-mortem examination exhibited extreme peritonitis, and residues of a chronic disease, which had left some calcified mesenteric glands. The disease had progressed, and made deposits between the glandular and muscular coats of the stomach. From these patches capillary oozing had taken place, but there was no surface ulceration. Death was no doubt mainly due to the absorption of the septic poison from the effusion in the peritoneal cavity. Reliable information led to the impression that the condition was one caused by inherited enthetic disease. Of this, however, the body presented no outward signs whatever. If, therefore, such a disease was the cause, it had remained localised to the abdominal cavity. The communication was concluded with some observations on the poisonous character of the effusion in most cases of peritonitis. Dr. Thudichum then described some cases of ammonuria. They are rare and incurable forms of decomposition of the urea within the bladder by microzymes which were exhibited, dyed with blue pigment. The patients suffer much from the formation of crystals of triple phosphates of magnesia and ammonia within the bladder. Local antiseptic applications diminish the trouble, but neither they nor any internal remedies, as yet tried, have cured it. *Folia uvæ ursi* had done the most service—possibly by the arbutin to which the decomposition of their extract in the body gave rise. Dr. Thudichum also alluded to the possible transfer of microzymes by catheters, and exhibited a little apparatus for disinfecting them by steam. The bent end of the catheter is fixed in a pierced cork, and this is fixed in the neck of a little copper flask suspended over a spirit lamp. The boiling water sends a current of steam through the catheter which is thereby completely cleaned and disinfected. During the steaming the wire plug is only loosened, not withdrawn, so that it also is thoroughly sterilised.

A paper was then read by Mr. HOWARD MARSH on some CASES OF OSTOTOMY, which will be found at page 353.

SHEFFIELD MEDICO-CHIRURGICAL SOCIETY.

THURSDAY, MARCH 6TH, 1884.

Dr. H. F. BANHAM, President, in the Chair.

CHANCER OF EYEBROW.

Mr. G. H. THORPE introduced a patient with an indurated sore at the outer side of the left eyebrow. The chancre had nearly healed. There were secondary symptoms.

TRIFID TRACHEA.

Dr. SINCLAIR WHITE exhibited a trifid trachea from a male, æt. 45. The third bronchus corresponded to the upper lobe of the right lung.

ADENO-SARCOMA OF BREAST.

Dr. S. WHITE also showed an adeno-sarcoma removed from the left breast of a patient of Dr. Keeling's. She was aged 20, and the growth was of two years' duration. The microscopical sections showed much fibrous tissue between the contracted gland ducts.

LUMBRICOID WORMS.

Dr. CLEAVER showed a number of lumbricoid worms, upwards of 100, which had been passed by a child, æt. 3, within seven days, by the help of *santonin* and *calomel*.

URIC ACID CALCULI.

Dr. CLEAVER showed also two uric acid calculi, extracted at different times, from the bladder of a boy. The first time lithotomy was performed upon him he was two years and five months old, and nine months after he was again operated upon, and the second stone extracted. There were no appearances of facets on either of the calculi. Both cases occurred in the Children's Hospital.

MEMBRANOUS CASTS OF THE BOWEL.

Mr. EDWARD BARBER gave particulars of a case of chronic inflammation of the bowels, attended with the passage *per anum* of enormous quantities of false membranes, which were in fact casts of the bowel. He exhibited the quantity that had been voided in the last twenty-four hours. The membrane was of a soft, gelatinous consistency, and of a greenish-brown colour. The patient was a woman, æt. 37, who had been married fourteen years, and had no children. She suffered a good deal from neuralgia, was of a dull and desponding nature, and was beginning to exhibit symptoms of pronounced hypochondriasis.

Drs. LAW and BANHAM referred to similar cases that had occurred in their own practices, and Dr. KEELING pointed out that there was an essential difference between the membranes exhibited and those given off from the uterus in cases of membranous dysmenorrhœa.

BRIGHT'S DISEASE—URÆMIC AMAUROSIS.

Dr. HARGREAVES exhibited the kidneys from, and related particulars of, this case. The patient, a fairly temperate man, æt. 27, was seized with great pain and heaviness in the forehead, and next day complete blindness ensued, which lasted for forty-three hours and then passed off. There was no albumen in the urine at this time, but it appeared in great quantities suddenly a week later, and continued so, with casts. With improved health, he indulged more freely in eating, and was seized with uræmic convulsions, followed by two other attacks, at intervals of ten and five days. Shortly after he was seized with catarrhal symptoms, copious dark sputum, but no blood in urine or purpura of skin. Cheyne-Stokes respiration was a marked symptom. He died fourteen weeks after the occurrence of amaurosis.

SYPHILITIC PARAPLEGIA.

Dr. PORTER read a paper on "syphilitic paraplegia," with notes of a case. The patient had been under his care in the Sheffield Public Hospital and Dispensary with symptoms which pointed to implication of the anterior portion of the cord, about the level of the second lumbar nerve. Although the patient's appearance and history, and the evidence remaining of former affections, were sufficiently characteristic of syphilis, the source of the poison was not satisfactorily accounted for. The patient, however, made a wonderfully rapid recovery under large doses of iodide of potassium, and in less than a month from his admission into the hospital, was walking about with very little trace left of the paralysis from which he had suffered. In speaking generally of syphilitic lesions of the spinal cord, Dr. Porter quoted cases mentioned by Lancereaux and Buzzard, in which post-mortem examinations had been made. The former author divided intra-spinal syphilitic growth into two kinds—the *diffused* which bore the character of sclerosis, and had been seen to involve large tracts, or even the entire length of the spinal

cord, and the *circumscribed* variety, which resembled the ordinary gumma. These syphilitic growths appeared to have a preference for the anterior or motor portions of the cord, and, as Lancereaux had said, they generally left intact, in part at least, the sensibility, and above all, the reflex movements of the extremities. This persistence of reflex movements, with complete paraplegia, Lancereaux regards as a characteristic distinction between tumours of the meninges and growths involving principally the substance of the cord, and Dr. Porter considered that these remarks in every respect corroborated the view he had taken of the nature and situation of the growth in the case he had read.

Remarks were made by the President, Dr. Keeling and Law.

France.

[FROM OUR SPECIAL CORRESPONDENT.]

DISPLACEMENT OF THE BRAIN.—At the Académie de Médecine, M. Luys made an interesting communication on the displacement of the brain in the different attitudes of the body. According to him, the cerebral mass, which does not completely fill the cranial cavity, follows the position of the head, and in this it is facilitated by the lubricity of the arachnoid membrane. In the horizontal position and upon the back, the brain falls by its weight on the occipital region, leaving an empty space in front; when lying on the face, the empty space is behind; while in the vertical position, the cerebral mass "settles down." These movements are entirely automatic, the brain moving by its own weight; and M. Luys considers that the vertigo so frequently observed in convalescents when they pass suddenly from the horizontal to the upright position is mainly due to this mobility of the brain. Sea-sickness would derive its origin from the same cause; the rapid and successive shocks experienced by the brain from the rolling of the boat produces this special state of nausea, hence the advantage of keeping the horizontal position until the phenomenon were off. The intense pain experienced in meningitis was produced by the inflamed membrane hindering these physiological movements of the brain. Individuals the subjects of cardiac affections or cerebral congestions suffer frequently from vertigo daze, or even apoplexy, in substituting the vertical for the horizontal position. In fits of coughing, and especially such as are witnessed in whooping-cough, the brain is, so to speak, projected against the cranial vault, producing that special kind of painful phenomena which is so often accompanied by serious trouble in children.

THE SPECIFIC TREATMENT OF DIPHTHERIA.—M. Dethil read a paper on this subject at the same meeting of the Academy. According to him, the combustion resulting from a mixture of coal-tar and turpentine, in the proportion of seven ounces of the one to three ounces of the other, renewed every three hours, is a specific remedy of diphtheria. 2. These fumigations dissolve the false membranes. 3. At the *debut* of the disease they arrest its progress. 4. They have also the advantage of protecting those who are about the patient; and by their paraside properties they are excellent in preventing contagion in schools and public establishments.

A CASE OF GASTROSTOMY.—At the Société de Chirurgie, M. Terrillon reported a case of gastrostomy, which he practised recently on a man, æt. 61, for cancer of the upper extremity of the œsophagus. The operation was done according to the classic method—the stomach was opened on the spot and fixed to the abdominal wall by ten sutures. The following day the patient was attacked with hemiplegia, and forty-eight hours afterwards succumbed, although he had been

able to digest three repasts consisting of the yellow of egg beaten up in milk. At the autopsy no trace of peritonitis was found; the edges of the wound were united; nothing was found in the brain to account for the hemiplegia, but the kidneys presented evident signs of interstitial nephritis; and he considered that death should be attributed to uræmic phenomena hastened by the administration of chloroform.

THE POPULATION OF FRANCE.—The following may be taken as reliable statistics: Of the 37,672,048 inhabitants of France 1,101,090 are foreigners, of which 432,265 are Belgians, 240,733 Italians, 81,986 Germans, 73,781 Spanish, 66,281 Swiss, and 37,006 English. The number of foreigners naturalised is small, only 77,046.

TREATMENT OF ACUTE CATARRH OF THE BLADDER.—The treatment recommended by Dr. Boegerold consists in administering chlorate of potash as follows:—

Chlorate of potash, 3ij;

Syrups of orange, 3j;

Water, 3vj.

A tablespoonful every two hours.

Under the influence of the salt the urine loses its ammoniacal character and becomes acids. In a short time under this treatment the complete cure of the vesical catarrh is obtained.

Department of Lunacy.

INCREASE OF INSANITY IN FRANCE: ITS CAUSES.

OUR French correspondent writes:—

LAST week M. Legrand du Saulle inaugurated at the Salpêtrière by a brilliant discourse his annual clinical lessons on the insane. The amphitheatre was filled with not only his most distinguished *confrères*, but with magistrates, barristers, and others of the laity, attracted by the subject, which could not fail to interest the public at large—"The Influence of the Political Events of the Years 1870-71 in the Increasing Number of the Insane, and especially in Children born during that Period, and who are now familiarly styled 'Children of the Siege.'" The eminent alienist commenced by saying that during the last fourteen years thirty-five thousand lunatics were examined by him at the Prefecture of Police. Of this number four thousand six hundred were found to be no more than eccentric. As to the horrors of the Commune, he said that they did not appear to affect the population to the extent that might have been supposed. Revolutions necessarily produce a certain accentuation in the delirium of those already affected or in bringing to eclosion the mental derangement a little earlier. The true cause, according to him, in this third quarter of the century, is the thirst of enjoyment, the passion of riches, vicissitudes of fortune, the risks on the Exchange, and above all alcoholism, which from 1870 to 1884 represented 25 per cent. of the whole! Curious to relate, a diminution in the cases of mental alienation was observed in the days which followed the declaration of war in 1870. On the other hand, a large number of cases of delirium tremens were observed as the men gave themselves up in their enthusiasm to immoderate libations. But when the siege commenced, another kind of delirium was almost to be observed in every street, that of inanition. This delirium was observed chiefly among women and children. Another curious fact was that during all the horrors of the siege no apparent increase in the attacks of epileptics were observed. Also when hostilities were suspended, and the gates were opened, through which food poured in abundance, the people, hitherto perishing with hunger, instead of rejoicing at the sight of bread, they seemed completely indifferent to all that was passing, for their spirit

was broken. As to the "children of the siege," that is, those conceived during that period, with the inanition of the mothers, the alcoholisms of the fathers, the cannon in the distance, hopes and despair, defeat in the end and everywhere, it was not to be wondered at that they should present anomalies, intellectual and corporal. Out of 92 children born at this epoch examined by the lecturer, 64 were found to be deficient in physique and intellect. Of this last number 35 presented troubles of nutrition and malformations, and 21 were imbeciles. M. Legrand du Saulle concluded his interesting lecture by saying: "Before 1870 the Paris woman did not drink; since the war she has acquired that passion." Those words are only too true. Twenty years ago temperance societies would have been superfluous in France; to-day they would be very necessary. The Frenchman and the Frenchwoman are drifting rapidly down the current which must lead to their utter demoralisation and ruin. It is no uncommon sight to see men and women drunk in the streets even in the morning, and the worst of it is they indulge in absinthe, which infallibly causes softening of the brain, and in a short time too.

THE FRIENDS' RETREAT AT YORK.

THE Friends' Retreat for Lunatics at York is a venerable institution, which throughout its long existence has maintained a high character for humanity and steady well-doing, and which, although it has now put off a little of the staid sobriety of former days, and is dressed as gaily as any asylum going, has not, at the same time, dropped any particle of its benevolent purpose, or fallen off in the slightest degree in efficiency. Dr. Baker, who is now its chief medical officer has introduced many improvements, and is evidently determined to keep the Retreat abreast of the best asylums of the day in everything that pertains to the comfort, safety, and restoration to health of its afflicted inmates. He narrates a case which illustrates in a striking manner the retention of a power of recovery in even the most protracted and apparently hopeless cases of mental derangement, and the importance, therefore, of persevering in treatment long after its acute stage is over. "One of the recoveries," says Dr. Baker, "was that of a lady who had been insane for sixteen years, twelve of which she had spent in the York Retreat. Admitted in a condition of active suicidal melancholia, she has during most of this lengthened period required the closest and most watchful supervision both by night and by day, and has frequently taxed to the utmost the vigilance of the staff of this large hospital. No improvement in her mental state occurred until four years ago, and even then the improvement was so slight that the gradual elimination of the precautions against suicide was a constant cause of anxiety to those whose duty it was to endeavour to pilot her safely through this critical transition period of her life. In May, 1882, it was thought desirable to remove her to Belle Vue House, thus giving her the advantage of frequent change of scene and surroundings, and increased opportunity of association with healthy minds. In due time the further test was adopted of a visit to the seaside, and subsequently of a prolonged residence at a large hydropathic establishment, until in February, 1883, considering her mental health sufficiently re-established, I felt justified in advising her relatives that she no longer needed the care and guidance of the Retreat physicians."

His Royal Highness the Duke of Cambridge, K.G., has consented to open the International Health Exhibition, on behalf of the President, His Royal Highness the Prince of Wales, on Thursday, the 8th of May, at noon.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, APRIL 16, 1884.

THE FUTURE OF THE ROYAL COLLEGE OF SURGEONS OF ENGLAND.—II.*

THE Council of the College being the actual executive of the corporation, it is important that it should be carefully considered in each one of its several relations. As is well known, we might almost add, too well known, this body has long possessed an absolute right to control every arrangement made in connection with administrative work; and it is unquestionable that some such responsible authority is an indispensable agent in promoting the welfare of a great institution like that now under review. It should, however, be borne in mind that permanent success in this direction can be ensured only so long as the acts of the executive are realisations of the wishes of those who make up their institutions; and without in any way contending that the Council have intentionally neglected this duty on their part, it needs only to recall the general outcome of the recent meeting to be assured that past performances of the Council have sometimes been entirely other than what a majority of the Fellows and Members would have desired. We do not forget Mr. Marshall's vigorous defence of his colleagues, while saying this, nor his vehement declaration that no resolution of the Council has been precipitately passed; but notwithstanding, there are many who will agree with us that there is no sufficient consultation of the general wish of the College contained in the postponement from one meeting of Council to another of a vote on motions involving, at times, the most revolutionary changes in matters pertaining to common interests. We have the authority of the eminent President

himself for the statement, that what is affirmed by one Council is regarded as in no way binding on a Council later in office; and to what an undesirable extent such unrestricted freedom of action may occasionally proceed, has been fully demonstrated by Mr. Tweedy's reference to the gradual reduction of standard in the way of practical experience to which candidates for the Fellowship are required to attain. It would be perfectly just and proper to demand that no radical alteration affecting important matters like this should be finally settled, without the consent of the general body of the College given at the annual meeting; and then only after ample consideration of the proposed amendments had been rendered possible by prior publication of the suggestions formulated in Council.

Of course, a Council thus shorn of the absolute power now enjoyed by it, might present a far less attractive front to intending candidates for election to it, than at present; and it will be not unprofitable to inquire a little into the question of why, and for what reasons, membership of it is so eagerly sought now-a-days. Undoubtedly a certain honourable distinction attaches to a seat at the Council Board of the Royal College of Surgeons of England. Further than this, however, there are prospective advantages in view, which may be summed up as, emoluments, and the chair. The duties associated with office are by no means inconsiderable, and exact for their conscientious discharge a sacrifice of time which, to busy practitioners, may represent too serious a pecuniary loss to find recompense in even all the *prestige* the appointment confers. Consequently many who might otherwise be willing to accept office do not feel in a position to do so; and in the absence of a stimulus to exertion that is wanting where no criticism is ever encountered, the number of those who think it worth while to compete for the favours of an electorate, however small, must be always infinitely less than would be the case under other circumstances. Thus it is that choice, as a rule, is extended to gentlemen who are untrammelled by the burdens of a heavy practice, although sometimes it does occur that surgeons who lead busy professional lives are found among the members of the Council. In a body so constituted that will happen which, on a larger scale, is found to be the case in every similar conclave; the work to be done will be accomplished by those whose leisure is keenest, and whose inclination for such labour as is indulged in is greatest; and so the actual working Council becomes reduced to a few, or it may be one or two active members of the body. The cause of this is not far to seek. At the period of his election each new member is necessarily ignorant of the routine observed by the Council; and unless of an exceptionally inquiring turn of mind, equally so, also, of details of administration. Naturally, then, he falls in with the custom of listening to and accepting cut-and-dried statements; while, even if he wishes to discuss them, he will feel powerless to do so until more "at home" in his new sphere; and long before that time arrives he is likely to be in the majority of those who accept without question. In a shifting body, too, like the Council, no member of which is permanent, great dependence must be felt in the official who is a permanent attendant at the board—viz., the Secretary of

the College; he, more than they, is acquainted with the traditions and accepted needs of the College; and his opinions, though they may be proposed as mere suggestions, must carry a weight that no others can possess. A strong secretary, therefore, can, in a way, rule the Council; and so long as the general body of the College is debarred from participation in, or from any power of determining the direction of, the proceedings of the Council, the state of things here sketched must obviously continue.

We have purposely refrained from expressing any opinion on the results obtained from past continuance of this system; for in the abstract, did even the best possible consequences flow from it, it would still be undesirable, for the sole reason that it excludes the collegiate constituency as a whole from having a voice in the management of collegiate affairs.

That which it is above all important to recognise at the present juncture, is that an irresponsible government, of whatever kind, tends irresistibly to grow autocratic, and to pursue a course that must of necessity be at variance with general desire. It is healthful for a ruling power to know that its every action must be accounted for to those from whom its power is derived, and who, at the same time, are individually governed by its decisions. The sense of responsibility so incurred is absent from the Council of the College of Surgeons; and it is highly necessary for it to assume sway over it. When this is achieved, its members will for the first time realise that the future contains more for them than a possible President's gown and such solid rewards as may fall to them as officials of a great examining corporation, considerable though each of these may be separately. Then, too, the wire-pulling spirit that pervades the Council, and that is monopolised by a few of its members, will perforce give place to broader lines of action, which will be shared and assisted by the whole board collectively.

HOPEFULNESS IN PROGNOSIS, AND PROFESSIONAL MANNER—A REMEDIAL MEASURE.

THERE are few points in the practice of medicine of greater importance to our patients and to ourselves than the possession of the happy knack of giving proper expression to our opinion of a patient's present condition, and of his or her prospects in the future. We take it for granted that our readers are all well up in their profession, close and accurate clinical observers, and in every way competent to practice their art with benefit to the public at large. Some, however, are much more successful men than others, though equal in professional attainments. Why should this be the case? The answer to this question will be found in the difference in manner and power of giving happy expression to the opinions formed in connection with the case that may be under notice. In the one instance the opinion is given with a blunt indifference to the feelings of the hearers; the symptoms seem to warrant a gloomy outlook; all that science seems to suggest may have been done; untried remedies may have been put aside, either from want of faith in their efficacy, or from an apparently well-grounded fear that they might prove hurtful rather than beneficial, and that the remedy might thus become worse than the

disease; the loaded, dry tongue, brown and parched, the pinched features, glassy eye, weak, rapid, variable pulse, and the steady progress from bad to worse—all seem to give premonition of approaching death. Stimulants, external and internal, nourishment and drugs secure no response. Wanting in hopefulness of character and buoyancy, tired of the battle, the medical man loses heart, pronounces the patient's condition as beyond hope, and sometimes rashly fixes the limits within which death may be expected. In many cases, of course, the prediction is verified, and, indeed, unconsciously, the medical man gives a helping hand in securing a verification of his opinion, for he imparts to his hearers his own want of faith and hope, and after his departure the invalid's attendants cease from their attentions and exertions, and sit down to await in patience the expected result.

On the other hand, the medical man whose nature and spirit are buoyant and hopeful, who, no matter how badly the case may look, how futile the apparent results may be from the exhibition of the remedies used, still hopes almost against hope; who, whilst admitting that he is but the instrument in the hands of a supreme power, still feels it his duty to persevere and to leave no stone unturned to avert death, often has the satisfaction of seeing the clouds of threatening death disperse, and his patient gradually emerging from his dangerous condition into the sunshine of convalescence. "Never despair" should be the doctor's motto. How, then, ought one's opinion to be given so as not, on the one hand, to allow the patient or his friends to remain in a fool's paradise, trusting implicitly that it is within the doctor's power to avert the threatened danger, or, on the other, to plunge them into the apathy of despair? In the one case, the end arriving and finding them unprepared breaks their faith in the medical man's knowledge and foresight, and induces them to reproach him for not having warned them in time. In the other, hope being lost, activity ceases, half-heartedness becomes a real danger to the sufferer, remedial measures are neglected, or, if still carried out, are used without spirit or faith in their efficacy, and so an extinguisher is put upon the few remaining chances of a fight for life. "Why should we trouble or worry him?" "Let him die easy" are the ideas that find place in the minds and on the lips of those around. We have often heard how one old, well known, and highly respected practitioner in the midland counties was accustomed to express himself to the relatives of those amongst his patients whose condition seemed critical. His expression was: "We must hope for the best and prepare for the worst." The only addition we would make would be: "We must hope and *fight* for the best, and be prepared for the worst." To the last the spirit of hope should not be lost. Whilst fully recognising and explaining to those around the danger, still the numberless instances of recovery in apparently hopeless cases should be steadily borne in mind; and no means should be left untried in the effort to turn the balance.

As the practitioner's experience widens out with extending years, he will have almost numberless examples to look back upon, where hope and effort may reasonably be credited with having turned the scale in favour of recovery where such a result seemed hopeless. Hopefulness

cannot prove hurtful if the medical man fully recognises the patient's danger, and makes it plain that he is fully alive to it and does not in any sense make light of it. On the contrary, being fully sensible of it, he shows that he means to meet and fight it inch by inch, and not to yield any one point until bound to confess that he has been driven from it only to take up a new and possibly a stronger position. Cheerful of face, sympathetic and hopeful in manner, speaking openly to the friends of the danger, and, if must be, to the patients themselves, still keeping steadily before them the fact that seemingly desperate cases have recovered before, and that the present case may prove to be one more of the number—the medical man will encourage the patients to obedience, the friends to exertion, and keep his own mind thoroughly alive to every point that may possibly prove of benefit. Forced by the failure of one remedy after another to do good, he may at last in desperation be driven to try the effects of some drug or combination of drugs, from the use of which he had previously shrunk, fearing that damage might be the result, only to find the solution of his difficulties, and the pleasant clearing-up of every unpleasant symptom. Abundant examples occur to the mind, illustrative of the soundness of the dogma, "Keep pegging away and be hopeful." If failure is the result, one loses nothing; on the contrary, one wins the gratitude and esteem of all the survivors; if success, then one's name and credit stand higher than ever, and the proud consciousness remains that we have done our duty, and that it has been abundantly rewarded by the success attained.

There is one thing that young practitioners ought carefully to avoid—i.e., sudden extremes in opinion, one day making light of the complaints of their patients, under the idea that doing so will encourage them, and the next, on finding a little change for the worse, expressing grave fears for the future, and an unreasonable sense of the gravity of the case. The public are sure, under such circumstances, to draw the most unfavourable conclusions as to the medical man's skill. If really bad, they say he ought to have known it before; if a quick recovery ensues after the serious view has been expressed, confidence is altogether shaken, and his reputation suffers all the more heavily from the natural reaction that ensues on the burthen of anxious fear being removed. In this, as in everything else, "the middle course is the safest." To secure success, and legitimate success, the medical man must cultivate a buoyant, hopeful state of mind; he should be cautious in what he says, close in his attention to his patient, energetic in his treatment, not alone in the case of mere drugs, which may often be only very secondary means in the treatment, but in everything connected with the patients and their surroundings. He should never lose heart, but fight on to the end, and he should try, under all circumstances, to be equable in his manner and in the expression of his opinions, carefully avoiding the extremes of either hope or despair. The one maxim constantly present to his mind might be—"Obviate the tendency to death," and then leave the future to take care of itself and its results. The art of medicine has never attained to, nor is it likely ever to attain to, the exactitude of a science. Much is known of the structure of

that most complex of all complex pieces of machinery, the human body, and of the functions of the various organs which administer to its existence and well-being; but we are convinced that much must ever remain a mystery, beyond even the possibility of exact knowledge, an unknown quantity that cannot be left out of our calculations, and which will often prove a disturbing element in our most careful estimate of a patient's chances of life, even under apparently the most desperate circumstances. The reaction between the effects of drugs on the one hand and individual susceptibility to these effects on the other, must ever remain matters of empiricism and uncertainty, and although we make a fair forecast, yet we can never make a certain prediction of what must be the result in a given case if we are prepared steadily and anxiously to fight the battle for life out to the bitter end, and not acknowledge that we are defeated, until certain that life has departed.

It is this element of uncertainty that cheers us on and enables us to the last to encourage a patient's friends to persevere. Hopefulness on our part is in itself a remedial measure for our patients. Daily we experience in our own lives the effect of cheerful and pleasant thoughts and surroundings as antidotes to the effects of fatigue and depression. Pleasant thoughts are in themselves a nerve tonic and stimulant of no mean order and power—a fact abundantly illustrated by common experience. This being the case in health, how much is it likely to prove beneficial in the treatment of disease? We are satisfied, that is often just the fillip required to rouse the patient's energies, and so to act upon the nervous system as to secure the efficacious working of the other methods of treatment that may have been adopted.

It is pleasant to hear one's patient say, "Ah, doctor, a look at you is as good as a bottle of physic;" and we are satisfied there is far more truth in the saying than is generally suspected. It is truly pleasant to feel that the looked-for visit leaves the patient with a fresh draught of hope, brighter and more cheerful, although perfectly alive to the danger he is in, because he has faith that all that can be done will be done, and because he can still be honestly led to hope that the natural powers of his body may prove the stronger in the tussle with disease. This element of "hopefulness" must never be left out of sight, but must steadily be impressed upon the minds of all, patients, friends, and, most of all, the medical man himself, as a distinct remedial measure in the treatment of disease; and those who are possessed of the largest share of it are likely to obtain the best results.

We, therefore, would impress upon the minds of all our readers the dogma—"Be hopeful in the treatment of disease, and, with proper restrictions, always so in the opinion you give of your patient's future." Ours the task to do the very best that lies in our power; having done so, the issues of life and death lie in the hands of a Higher Power. We are His instruments, but, having done our best, we must bow in submission to His will.

THE MEDICAL BILL.

THE unexpectedly large majority of the House of Commons which voted the second reading of the Franchise Bill has put it beyond reasonable doubt that the

Medical Bill will pass during the present session unless the anticipated apposition of licensing bodies acquires sufficient solidity to stop it. The difficulties of the political situation which the opponents of the Bill depended on as their most potent ally in their attempt to throw it out may be said to have been cleared away, and without doubt the question will be fought out on the second reading within the next month. We congratulate all parties to the dispute on this anticipation, because we think it much better that the battle of medical reform should be fought out now than to have perpetuated the present state of suspended animation in medico-educational affairs. All parties are paralysed in action by this state of suspense: the Medical Council seems to think that self-improvement is too late; the licensing bodies confine their action to bogus conjoint schemes, got up for the purpose of discrediting the reform movement, and they take no earnest interest in real improvements of system; and the profession awaits with patience the new constitution which is to emancipate medical affairs from the pocket interests of teachers, grinders, and examiners, and give the medical practitioner some voice in the adjustment of his own business.

The second reading of the Bill in the Commons will probably be taken within a fortnight after the Easter recess, and, though it will be vigorously opposed, it will certainly pass as an enunciation of the principles of the Bill, a declaration that the existing state of affairs cannot continue, that a limitation must be imposed upon the granting of licences to practise, that the licensing bodies must be put under control, that the Medical Council should be rejuvenated, and that neither the Huxley dogma nor any of the expedients for preserving the *status quo* can be listened to.

It is when the Bill reaches the Committee stage that the real contest of opinion will take place, for there is hardly a clause of it which may not be disputed by one or other party. The Government has, we believe, not very strong opinions on the subject, save to maintain the leading principles laid down by the Royal Commission, and we are aware that Lord Carlingford and Mr. Mundella are quite prepared to concede any changes, consistent with these principles, which may be urged with sufficient strength in the House. We shall not be sorry to see the needful amendments of the Bill (and they are many) pressed with earnestness and influence when the Bill is in Committee, because we do not share in those apprehensions of endangering the passing of the measure which certain *soi-disant* reformers are using as an excuse for giving themselves no trouble to amend it. We will go so far as to say that the measure in its present unamended state would be of little advantage to medical reform—that it would inevitably result in a fresh muddle, and a new agitation for changes which ought now to be introduced into it, and would yield to the profession little else than bitter regrets that no steps were taken to correct its faults while there was yet time. The crisis of medical reform is upon us, and we certainly trust that those who have assumed the position of leaders of reform will wake up and rub their eyes and realise that their work is only half done, and that, if it be turned out in its present unworkmanlike state, they will be

liable to the charge of having talked much and done little, and of having botched the legislative mechanism entrusted to them for mending.

THE TERCENTENARY OF THE UNIVERSITY OF EDINBURGH.

THIS week the University celebrates the three hundredth anniversary of the date of its foundation with all the pomp and rejoicing which is befitting to such an occasion. The University in so doing has every reason to be proud of its past history, for it stands boldly forward as a monument of that indomitable courage and devoted love for knowledge which are characteristic of the Scottish nation, and which have made Scotchmen the pioneers of education in all the colonies of the United Kingdom. Passing by the general history of the University which is so ably treated in our contemporary the *Scotsman*, we propose to confine our remarks to that portion which more intimately interests us, and which deals with the rise and progress of its medical school. Of this department it may be said, *si monumentum queris*, behold it in its teeming class-rooms filled with students from all parts of the world, behold it in the numbers of medical men to be found everywhere holding high positions as teachers in home and colonial universities, and in the still larger band of men everywhere struggling with disease who have drawn their knowledge and inspiration from the University which, though three hundred years have passed since its foundation, is more fresh and active than ever. Those of our readers interested in the origin of the Edinburgh School of Medicine will find a most interesting account of it in Dr. John Gairdner's "Historical Sketch of the Royal College of Surgeons of Edinburgh," a pamphlet which is now becoming scarce. The reader will there find that it was to the enlightened efforts of the College of Surgeons that Edinburgh owes the germ of its greatness as a centre of medical education. The first professors in the University had been teachers and professors in the College, and, in fact, for many years the College was the nursery in which the University professors were trained. To some extent the Extra-Mural School, in which the Colleges, for we must now include the College of Physicians, in a somewhat half-hearted manner have interested themselves, still supplies the University with its best teachers. In speaking of the Edinburgh Medical School it must always be borne in mind that it is not the University alone which constitutes the school, but that the medical school is composed of two factors, the University and the Extra-Mural School, which in point of age is the parent of the University School. For the benefit of our readers we may state that the Extra-Mural School is composed of individual lecturers, who, before becoming teachers, must be Fellows, with one or two exceptions, of one or other of the Colleges, and must have passed an examination on the subject they propose to teach, and received a licence from the College to which they are attached. It will thus be seen that Edinburgh is not only a school for students, but it is also as it were the training college for teachers; hence it is not surprising that Edinburgh holds the honourable and proud position of being able to supply teachers to other schools. In Aberdeen, for instance, of the five professors with which Edinburgh has supplied them, four have been Extra-Mural lecturers. The

Extra-Mural School has also had a most beneficent and stimulating effect on the University professors, for by entering into a vigorous rivalry with them the teaching in the University has been compelled to keep pace with the requirements and demands of the times. It is to be regretted, however, that the value of this honourable rivalry has been somewhat impaired by the fact that the number of classes which students are allowed to attend outside the University is limited, and that the examination of students by the professors has a tendency, as the late Professor Syme stated in a public address, "on the reform of medical education," to cause students to "attend lectures without any expectation of benefit, and merely to propitiate their examiners." This objection has, to some extent, been removed by the appointment of assessors to the professors for the examination of candidates, and we would modestly congratulate ourselves on the fact that to our strenuous efforts a larger share of these appointments have of late been accorded to the Extra-Mural lecturers, for it is well known that the selection of an examiner is virtually in the hands of each professor. We have tried to give a short account of the Edinburgh Medical School as it now exists, and to point out some of the reasons for the rapid strides it has made as a medical school; but there are other factors to which we would briefly refer. The clinical teaching is sound and good, and this, we have had opportunities for knowing, is duly appreciated. The fact is, that what talent there is in Edinburgh is not, as in the case of London, divided among several hospitals, but is concentrated in the Infirmary, and it must also be noted that teaching, as a rule, is not made a stepping-stone to practice, but is to a large extent the means of living. The competition may be keen, and not always conducted on broad principles, but the Edinburgh student is benefited, and has, therefore, no reason to complain. In conclusion, we have to congratulate the University on the greatness of its successes and the brilliancy of the work it is doing, and we would wish God speed in the future.

Notes on Current Topics.

Epidemic of Measles at Canterbury.

A VERY severe epidemic of measles has broken out at Canterbury, where no less than one hundred and forty cases have been reported by the medical officer of health as having occurred within a fortnight. During the same period three deaths have been certified as caused by the disease, and the danger has been regarded as reason sufficient to justify the closing of all the infant schools of the city for a time. The request of the sanitary authority to this effect has, however, been ignored in one instance, the secretary of the school in question, a clergyman and vicar of the parish, arguing as the ground of his refusal, that compliance with the order is unnecessary in this particular case. It is to be hoped that the reverend gentleman's obduracy may not be permitted to perpetuate the risk of infection to which the neighbourhood will be subjected through it; and that he will speedily be brought to a clear understanding of his civil obligations as a school manager under the new Education Code. One of the sections of this provides for

compliance with any notice of the sanitary authority requiring managers, either to close their schools for a specified time, or to exclude certain scholars from attendance under circumstances which seem to render such proceedings necessary for protecting public health. The medical officer, moreover, has already stated his opinion that the epidemic would not have assumed its present proportions had the schools been closed at an earlier date; and the sanitary authority is now resolved to enforce the powers confided to it, in face of any opposition it may encounter.

Police Ambulance Classes.

THE institution of classes for the instruction of police constables on questions relating to the immediate treatment of persons accidentally injured, is one of the most salutary improvements ever devised with a view to reducing the dangers arising from this cause. Sir William MacCormac gave evidence of this in a speech addressed to an assembly of policemen at Scotland Yard, on Thursday last, when Lady MacCormac distributed over one hundred certificates gained by members of the force who had attended ambulance classes at various centres in the metropolis. Although of such recent origin, these classes have already been the means of doing an incalculable amount of good; the kind of teaching given to them is exactly that which is likely to be made use of in critical moments, when the result of an injury materially depends on whether or not a common-sense mode of dealing with it on the spot, and until skilled assistance can be invoked for it, is adopted. By means of appliances always at hand, and which every ambulance pupil can forthwith put into use, fractures and other injuries are frequently now brought into hospital in a condition of security which was never exhibited by them until police officers were made acquainted with the principles of first aid in such cases. The ceremony of Thursday was, therefore, a gratifying indication of the further extension of the ambulance movement; including those who received certificates on that occasion, there are at present 1,312 metropolitan constables who hold the certificate of the St. John's Association.

Death of Mr. Charles Reade.

ENGLISH literature has sustained an irreparable loss by the death of Mr. Charles Reade, which occurred on Friday last, at the London residence of the deceased novelist. As a writer of high-class fiction the author of "Christie Johnson" occupied a foremost position among English literary celebrities, while his claims to general scholarship ranked scarcely less important than those he possessed as a story-teller. In questions relating to the well-being of the people, moreover, Mr. Reade was ever deeply interested; and though the labours in which he chiefly engaged did not bring him directly into the arena of scientific activity, he yet accomplished a great deal in the way of aiding medical men to accomplish better work. Two of his novels, "It's Never Too Late to Mend," and "Hard Cash," were powerful instruments in securing attention to, and improvement of the evils which formerly disgraced, prison administration and the treatment of the insane in asylums, respectively; and for the good he thus achieved, not less than for his special qualities as a man

of letters, he will long be held in grateful memory. Charles Reade was a Fellow of Magdalen College, Oxford, having succeeded to this under the old rules, by which scholars of the College proceeded to Fellowships on a corresponding foundation as vacancies occurred. He was also a D.C.L. of the University, and in 1842 obtained the Vinerian Fellowship. He had been in a low state of health for some time past, and had lately sought improvement at Nice, where he was constantly attended by Dr. Chapman. A few days ago, however, he was so much worse that it was deemed necessary to hasten his return home, where, notwithstanding the unremitting care of his own physician, Dr. Chapman, in conjunction with Sir Joseph Fayrer and Dr. Wilks, he slowly sank, and died on Friday afternoon, at Shepherd's Bush. The maladies from which Dr. Reade had so long suffered were emphysema and enlargement of the liver.

Death of Jean Baptiste Dumas.

THE death took place on Friday morning last, at Cannes, of the world-famous chemist and physiologist, Jean Baptiste Dumas. To him we owe a great part of the knowledge which rendered the modern science of physiological chemistry so materially useful as an agent of therapeutic advance; and his decease will call forth an expression of sincere regret from the whole world of science. Dumas was perpetual secretary of the Academy of Sciences, having been elected to this post on the death of the illustrious Flourens; and on the decease of Guizot he succeeded to the chair of the latter at the Académie Française. In 1869 our own Royal Society conferred upon him the Faraday Gold Medal; and the late Emperor Napoleon gave him the Grand Cross of the Legion of Honour in 1863.

Jacksonian Prize.

THE Jacksonian Prize for the present year has been awarded to Mr. Frederick Treves, F.R.C.S., Assistant Surgeon to the London Hospital, and Examiner in Anatomy at the University of Aberdeen. The subject of the essay is "Pathology, Diagnosis, and Treatment of Obstruction of the Intestines in its various Forms in the Abdominal Cavity." Mr. Treves has previously communicated to the Royal Medical and Chirurgical Society a record of his experiences of the operation of enterectomy, and is the author of a new and most ingenious method for securing accurate union of the divided edges of the intestine.

Extra-Uterine Pregnancy.

FREUD, the well-known gynecologist of Strasburg, has recently published some observations on fifteen cases of extra-uterine pregnancy observed by him. In regard to etiology, he attributes some importance to movements of the Fallopian tubes during coitus, such, for instance, as may be caused by fear, &c. He divides the condition into four groups—1. Pregnancy in previously formed limited muscular cavities: tubular pregnancy, interstitial pregnancy, and pregnancy in the undeveloped cornu of a uterus bicornis. 2. Ovarian pregnancy. 3. Abdominal pregnancy, with attachment of the placenta anywhere but to intestine. 4. Abdominal pregnancy, with attachment of placenta to intestine. In regard to treatment, within

the first three months he recommends in all cases puncture of the sac, thus bringing about the death of the fœtus. If the third month has passed and the fœtus be living he would wait till shortly before the end of the term, when he would operate by laparotomy. If, on the other hand, the fœtus be dead, he would wait as long as possible, but would operate at once if suppuration set in. In the two latter cases he recommends that the sac be stitched to the sides of the abdominal incision before opening, and that the placenta and membranes be left until they are cast off in order to avoid hæmorrhage. The cavity should be disinfected and plugged with lint.

Puerperal Mastitis.

In the *Archiv f. Gyn.*, Bd. 22, Hft. 2, Dr. Otto Küstner discusses the question whether puerperal mastitis can ever arise from the retention of milk within a milk duct. He has observed cases that have made it certain (to himself) that mastitis can be produced in this way. For a long time he held the views promulgated by Billroth and Winkel, that mastitis is invariably a secondary process, the result of infection, that the source of infection lies in rhagades and excoriations of the nipples, and that the accompanying milk retention is caused by swelling of the glandular tissues, but his observations have now led him to change his opinion. Schroeder considers blocking of the milk ducts and the consequent milk stasis to be the most frequent cause of mastitis. Küstner, on the other hand, believes that the affection only rarely arises in this way. When it does the patient has only suckled her child a short time or not at all, and rhagades have never been present. These cases run a milder course in regard to fever, pain, and redness than those inflammations that arise from infection. The infiltration may be dispersed (by pressure with the elastic bandage); in other cases the redness is circumscribed, and distinct fluctuation indicates incision. No pus, however, escapes, but milk in various stages of condensation. In such a case wide incisions, drainage, and antiseptic washings out are unnecessary. The wound generally heals quickly under a compress, and without the accumulation of fresh secretions.

Rupture of the Urinary Bladder.

DR. B. BECK, General and Corpsarzt of the 14th armée corps of the German army, has observed twenty-five cases of traumatic rupture of the bladder, and in the *Deutsche Zeit. f. Chirurgie*, xix, 4, 5, he reports two cases at length, and adds the following conclusions:—

1. That simple rupture of the bladder may be caused by direct or indirect violence—falls on the feet or the lower end of the trunk—and that the momentary position and attitude of the body contributes in determining the situation, form, and extent of such rupture. The bladder will always give way at its weakest part, the anterior or posterior wall, the point being determined by the direction in which the contents of the bladder are pressed by the outside force.

2. The only characteristic symptoms are those furnished by the wounded bladder itself, and these are: violent, frequently-returning attempts to urinate; inability to pass water spontaneously; flow of a small

quantity of bloody urine on passing the catheter; strong contraction of the bladder, whereby its capacity is diminished; free movability of the catheter, after which the small emptied space speedily fills up with some urine which sets up renewed straining. If bloody urine escapes the diagnosis may be made of extra-peritoneal rupture, as it is only rupture of the anterior wall in the vicinity of blood-vessels that give rise to hæmorrhages. Œdema of the external genitals, caused by disturbances of circulation, supports the diagnosis of extra-peritoneal rupture.

3. The fatal termination in cases of simple rupture of the bladder is not a consequence of peritonitis, but of intoxication by resorption of decomposed urine.

4. Internal medicines are insufficient. The first requirement is the introduction of a permanent catheter under strict antiseptic precautions.

As the urine that is poured out into the abdominal cavity is the greatest source of danger to the organism, the treatment in intra-peritoneal rupture should not be expectant. At the onset, or increase of local symptoms, if the general condition be gravely affected—and this will be seen in the course of a few hours—the following is the only mode of procedure calculated to save life:—Laparotomy, removal of the urine poured out into the abdominal cavity, thorough disinfection, and, finally, closure of the bladder wound by suture. In extra-peritoneal rupture, when the urine has permeated the extra-peritoneal connective tissue, an expectant plan of treatment is allowable so long as changes at the centre of infiltration do not point to the necessity for surgical interference. The main point in the treatment is the employment of a retaining catheter, with occasional cautious washing out of the bladder with some antiseptic fluid, in order that no fluids capable of becoming disorganised may be allowed to remain, to the jeopardy of the patient.

Antient Vaccination in India.

THE *Madras Times* publishes a letter from a correspondent who asserts that vaccination was practised from a very early date by the Hindoo Vythians. There will be found an extract of a letter to the *Madras Courier*, dated January, 1819, as follows: "Inoculation for the cow-pox was known of old time to the Hindoo medical writers. To substantiate this statement it is necessary only to refer to the *Sactiya Grantham*. In this work, after describing nine several species of the small-pox, of which three are declared incurable, the author proceeds to lay down the rules for the practice of inoculation. From this part the following extract is taken: 'Take the fluid of the pock on the udder of a cow, or on the arm between the shoulder and the elbow of a human subject, on the point of a lancet, and lance with it the arms between the shoulders and elbow until blood appears; then mixing the fluid with the blood, the fever of the small-pox will be produced.' If further proof is required that long before the English came to India inoculation proper was practised, a translation of a paper in the language of Orissa called Odiah, describing the manner in which the inhabitants of villages are inoculated by Odiah Brahmins is given below: 'A certain quantity of cotton

to be wetted with the matter of a favourable small-pox, and from 200 to 400 people assembled on Sunday and Thursday, a cut to be given upon their arms with an instrument.' Small-pox was accurately described by Rhazes, an Arabian, about the year 900. It is supposed to have been introduced into Europe by the Saracens."

The Anti-Epileptic Action of Bromide of Potassium.

EXPERIMENTS made by P. Rosenbach, of St. Petersburg, on dogs, with a view of ascertaining the effects of bromide of potassium, showed that when administered in sufficiently large doses, it abolished, or, at least diminished, the excitability of the cortical substance of the cerebrum to electrical irritation, whilst the excitability of the underlying white substance remained unchanged. It may then be concluded that the beneficial action of the drug in epilepsy is dependent on its capability of diminishing excitability.

The Medical Bill and Registration.

AN alteration has been introduced into the Medical Bill which is of some importance, especially to migratory or unbusiness-like members of the profession. Heretofore the Registrar was empowered to strike any name out of the official list if he had three months previously sent a letter to the published address and had received no reply. It seems to have been assumed that the omission to reply was sufficient proof of the disappearance of the party addressed, an assumption which was totally unwarranted, and which led to innumerable mistakes. Many of the persons so addressed had changed their residences; many others, though nominally resident at the published address, were away from home for the greater part of the year, serving in ships or in the army, while a multitude of others were too lazy, or too forgetful, or too busy to reply, and, moreover, the postal authorities seldom took the trouble to return the circulars when the addressee was not found. Thus it happened that many names were struck out of the Register, and had to be reinstated, the practitioner being charged 5s. for the new entry. Indeed, it became a part of the registration system to earn 5s. by striking out the name of a non-responding practitioner even although the Branch Registrar had evidence of his existence at the published address.

The erasure system came to be a nuisance to all concerned, and it is therefore provided by the Bill that, when no reply has been received from a practitioner within the stipulated time, the Registrar "shall place the name of such person on a separate list for one year, after which period that person shall" be deemed to have ceased to practise, and his name may be erased from the Register without his consent having been obtained. An additional protection is thus afforded practitioners against the consequences of mistakes of Post-office officials, or of their own neglect or carelessness.

The Health of Dublin.

FROM the report of Dr. Cameron, Superintendent Medical Officer of Health, we find that the deaths within the metropolitan area during the five weeks ended

2nd February were in the ratio of 26·37 per 1,000 persons living. On the northern side of the city the rate was 29·37, and on the southern side 30·19. The deaths from the seven principal zymotics were in the whole registration district in the ratio of 2·4 per 1,000 persons. As compared with the previous month, there was a decrease in the number of admissions of patients affected with the above-mentioned diseases. The following shows the death-rate within the municipal or city districts, 1882:—Death-rate per 1,000 persons from all causes—1882: Oct., 25·43; Nov., 27·4; Dec., 34·32. 1883: Oct., 27·44; Nov., 29·42; Dec., 34·76. 1884: Jan., 28·88. Seven principal zymotic diseases—1882: Oct., 1·97; Nov., 2·42; Dec., 3·25. 1883: Oct., 4·04; Nov., 3·42; Dec., 3·57. 1884: January, 2·81.

The Dwellings of the Poor.

In a paper read by Mr. Elijah Hoole before the Society of Arts, at their meeting on the 2nd inst., the author shows that the labouring classes may be housed as successfully as those of a higher grade, and rightly insists that the problem must be solved, not on eleemosynary principles, but on a sound financial basis.

Mr. Hoole recognises the truth that the cultivation of the domestic life of the working classes does not depend solely upon the supply of proper house accommodation, and that the lower the social strata dealt with, the greater is the necessity for benevolent and sufficient superintendence to inculcate habits of order, decency, and self-respect.

It is refreshing to find only one reference in the paper to necessity for legislation, especially when we reflect that the want referred to, viz., the omission from "Building Acts" of a clause requiring structural alterations in a private house adapted to a tenemental dwelling, is fully supplied by the repairing clauses in Torrens' Acts, 1868, '79. There is, we might almost say, a superabundance of legislation on this subject, and sanitary authorities have a bewildering choice of measures under which they can effect improvements, a choice so bewildering as often to produce inaction. There is no doubt that the present condition of the homes of the poor is due rather to defects of administration than of legislation, and the sanitary authorities in London have strangely neglected their duties in this respect.

We trust that if the Royal Commission at present sitting extends its inquiries to Dublin, our sanitary authority will be able to show that it has done its part not only in the work of demolition and reconstruction, but also in the equally important function, in this city, of the adaptation and maintenance of existing abodes.

The discussion which followed the reading of the paper is chiefly remarkable for having elicited from one of the speakers the extraordinary statement that the operations of the Glasgow "Improvement Trust" had been a failure financially and sanitarily. We wonder what Dr. Russell, Medical Officer of Health to Glasgow, will say to this!

THE new hospital buildings at Stratford-on-Avon, built by the liberality of Mr. W. B. Gibbins and his sister, are rapidly approaching completion, and will be open for the reception of patients at an early date.

Harmless Lunatics in Workhouses.

In the annual report of the Omagh District Asylum we find the following statement by Dr. Carre, the Resident Medical Superintendent:—

"The steady increase in the number of patients, and consequent overcrowding of the asylum, has been a source of much anxiety and serious consideration. The accommodation afforded by the fever hospital has enabled us to provide for all sent in, but fearing that this, which we could only look on as a temporary provision, might be taken from us by the outbreak of any infectious disease, it was proposed that quiet harmless patients, certified as such by the visiting physician and myself, should be sent to their respective workhouses, under the provisions of 38 and 39 Vic., cap. 67, sec. 9. As yet we have not succeeded in getting any taken off our hands."

THE highest annual death-rates from diseases of the zymotic class in the large towns last week were—From whooping-cough, 3·4 in Bolton, and 1·6 in London; from measles, 4·7 in Oldham, 2·7 in Wolverhampton, and 2·4 in Portsmouth; from scarlet fever, 2·6 in Preston, 2·2 in Leeds, and 1·7 in Sheffield; and from "fever," 1·4 in Blackburn. The 34 deaths from diphtheria included 14 in London, 5 in Glasgow, 4 in Cardiff, 3 in Birmingham, and 2 in Portsmouth. Small-pox caused 13 deaths in London, 3 in Birmingham, 2 in Liverpool, 2 in Sunderland, and 1 each in Edinburgh and Newcastle-upon-Tyne.

THE deaths registered last week in the principal large towns of the United Kingdom corresponded to an annual rate of 22·7 per 1,000 of their aggregate population. The death-rates in the several towns were:—Brighton, Huddersfield 14; Leicester 16; Bristol, Birkenhead 17; Hull, Bradford, Blackburn 18; Norwich 19; Salford, London 21; Sunderland, Derby, Sheffield 22; Bolton, Halifax, Birmingham, Portsmouth, Liverpool, Edinburgh 23; Newcastle-on-Tyne 24; Preston 25; Glasgow, Wolverhampton, Nottingham 26; Leeds, Plymouth 28; Dublin 29; Manchester 30; Cardiff 31; Oldham 36.

In the principal foreign cities the rates of mortality per 1,000 of the various populations were, according to the latest official returns, as follow:—Bombay 27, Madras 65, Paris 28, Geneva 45, Brussels 27, Amsterdam 28, Rotterdam 26, The Hague 24, Copenhagen 19, Stockholm 23, Christiania 22, St. Petersburg 42, Berlin 23, Hamburg 25, Dresden 22, Breslau 36, Munich 31, Vienna 27, Prague 40, Buda-Pesth 37, Trieste 29, Turin 43, Venice 28, Lisbon 30, New York 24, Brooklyn 17, Philadelphia 24, and Baltimore 21.

At the quarterly meeting of the Council of the Royal College of Veterinary Surgeons, held on Wednesday last, the following motion was proposed by Mr. H. L. Simpson, of Windsor, seconded by Mr. E. C. Dray, and carried by a very large majority:—"That the Council of the Royal College of Veterinary Surgeons hereby affirm that the operation of docking horses is a surgical operation requiring skill and anatomical knowledge for its humane performance, and that there are many circumstances which render the operation necessary."

At an influentially-attended meeting on Thursday last, presided over by the Earl of Carnarvon, a movement was set on foot for the erection and endowment of a hospital for Newbury, Berks. Subscriptions to the extent of £3,000 were announced as having been mainly raised through the influence and untiring labour of Dr. Douglas of that town.

SMALL-POX has shown signs of re-appearing in London. Last week the Registrar-General reported that the fatal cases had risen from three to fifteen during the week. Still, even this increase places the death-rate at fifteen below the average number.

Scotland.

[FROM OUR NORTHERN CORRESPONDENTS.]

GLASGOW.—DISPENSARY FOR SKIN DISEASES.—The twenty-third annual meeting of the Glasgow Dispensary for Skin Diseases was held in the Religious Institution Rooms, Glasgow, on the 9th inst., when Mr. A. Orr Ewing, M.P., occupied the chair. Professor McCall Anderson submitted the medical report, which showed that in the course of the twelve months over 1,200 patients had been treated, and about forty students had attended the practical course. It appeared from statements read by Mr. James Grahame, the honorary secretary, and Mr. A. S. McClelland, the honorary treasurer, that the institution was in a flourishing state. The Chairman, in moving the adoption of the various reports, pointed out that the institution was benefiting both the poor patients and medical science. It was hoped, he added, that a debt of upwards of £700 on the house property would be cleared off in a couple of years. The report was adopted, the list of office-bearers completed, and a number of votes of thanks awarded.

A MEDICAL MILLIONAIRE.—In the legitimate departments of medical practice it is surely rare indeed that a medical man dies a millionaire. We learn, however, from the *Pester Medizinisch-Chirurgische Presse* of the 9th March, 1884, that Dr. Andreas Wagner, of that city, died at the age of 72 in this category of affluence.

EDINBURGH HEALTH STATISTICS.—The mortality in Edinburgh for the week ending with Saturday, the 5th inst., was 107, and the death-rate 23 per 1,000 per annum. There were 15 deaths under one year, and 28 above 60 years, of which 4 were above 80 years. Diseases of the chest accounted for 50 deaths, and zymotic causes for 16 deaths, of which 3 were due to scarlatina and 2 to measles, the intimations of these diseases being 22 and 57 respectively.

MORTALITY IN GLASGOW.—The deaths in Glasgow during the week ending with Saturday, the 5th inst., were at the rate of 26 per 1,000 per annum, as compared with 27 in the preceding week, and 33, 25, and 29 in the corresponding periods of 1883, 1882, and 1881 respectively.

EDINBURGH ROYAL MATERNITY AND SIMPSON MEMORIAL HOSPITAL.—The Medical Board of this Hospital have agreed to the appointment of Thomas A. Fraser, M.B., C.M. (honours), M.R.C.S. Eng., and Archibald Donald, M.A., M.B., C.M. (honours), M.R.C.S. Eng., as House-Surgeons for the quarter beginning on 1st May. Dr. Angus Macdonald has been medical officer on duty during the past quarter, and he will be succeeded on the 1st May by Dr. Keiller.

GLASGOW ROYAL INFIRMARY.—At a meeting of the direc-

tors of this institution, held on the 10th inst., the number of surgeons was increased from five to six, and the number of physicians diminished from five to four. Considerable diversity of opinion existed as to the expediency of this change.

GLASGOW.—THE OUTBREAK OF SMALL-POX.—At a meeting of the Town Council of Glasgow, held on the 7th inst., Dr. Russell, the medical officer of health, reported as follows:—The same number of cases of small-pox has been registered as in the preceding fortnight, viz., 24. Of these 11 belong to the Eastern district, 6 to the Northern, 4 to the Central, 2 to the Western, and 1 to the Southern. All have been removed to hospital. Of these cases 11 are associated in two groups of 6 and 5 cases, the history of which illustrates well the insidious and obscure paths by which small-pox spreads. The 6 cases in the Northern district belong to one family living in a two-apartment house. The other group consists of 5 compositors, all employed in one printing office, but living in different quarters of the city. The first one discovered said an apprentice had been absent two days a fortnight ago, and on his return he remembered seeing on his arms as he went about with shirt sleeves rolled up, spots just like those on himself. We got hold of this apprentice, and the stains of the modified small-pox eruption were still visible. He belonged to a family living on a stair from which several cases have been removed, and had refused to be revaccinated. Fortunately, the 5 compositors are all extremely mild cases, indeed so mild that but for our getting on their track they might all have escaped recognition. The lessons I would draw from these facts are two—(1) That at this time any cutaneous eruption, however slight and insignificant, should be regarded with suspicion, especially if preceded by such symptoms as vomiting, backache, and feverishness. Employers, foremen and forewomen, and workers themselves, ought to keep a sharp look-out for suspicious eruptions on the face and arms, such as that observed on the apprentice printer, but, unfortunately, not mentioned until all the mischief was done. (2) The other lesson is that when small-pox is present in a community there is no safety for anyone belonging to it, or moving about in it, except in revaccination. Those trifling unrecognised cases occurring in persons vaccinated in infancy carry the infection everywhere.

THE EDINBURGH UNIVERSITY COURT.—At the meeting of this court, held last week, it was reported that it had been thought advisable not to proceed with the proposed alterations of Ordinance No. 5, Edinburgh No. 2, regarding attendance on practical classes of midwifery, physiology, pathology, and materia medica, in the form adopted at last meeting, as it did not appear fully to secure its object; and that it had accordingly been withdrawn by the Principal's instructions. The withdrawal of the form of the alterations referred to was approved, and the Court re-adopted the alterations in the following form:—Ordinance No. 5, Edinburgh No. 2, Section v. The paragraph relative to practical midwifery in sub-section 1 to be deleted, and to be inserted, in the form given below, as a new sub-section, to be numbered 5. In sub-section 3, as altered by order of Her Majesty in Council, of date 29th June, 1878, the words "and pharmacy," to be inserted after the words "materia medica;" and the part of the sub-section from the words "conducted by a teacher recognised by the University Court," to the end to be deleted, and the following to be substituted therefor:—"Conducted at the laboratory of an hospital or dispensary, or elsewhere, by a teacher recognised by the University Court under said subsection (4); or

that he has been engaged by apprenticeship for not less than two years with a registered medical practitioner, or a member of the Pharmaceutical Society of Great Britain, or a member of the Pharmaceutical Society of Ireland, or a pharmaceutical chemist, or chemist and druggist, registered under the provisions of the 'Act for regulating the Qualifications of Pharmaceutical Chemists, 1852,' 'The Pharmacy Act, 1868,' or 'The Pharmacy Act (Ireland), 1875,' in the *bond fide* compounding and dispensing of drugs, and the preparation of their official and other preparations under his superintendence." The following sub-sections to be added:—"5. That he has attended for at least three months the practice of a midwifery hospital, or that he has attended at least six cases of labour under the superintendence of a registered medical practitioner." "6. That he has attended, during courses of not less than fifty hours' instruction, classes of practical physiology and practical pathology in the University of Edinburgh, or in a university or school of medicine recognised by sub-sections (2) and (4) of Section VI. of Ordinance No. 8, *Edinburgh* No. 3, or upon classes thereof conducted by a teacher recognised by the University Court under the said sub-section (4)." The Secretary was instructed to take the usual steps for submitting the proposed alterations to the Chancellor of the University for his consent, and to Her Majesty in Council for her approval.

TERCENTENARY GOSSIP.

WHILE the pages of this journal are still damp from the press, Edinburgh will be all excitement and bustle celebrating the three hundredth birthday of its great and learned University. The child of the Reformation, nurtured in times that "tried men's souls," the University of Edinburgh, the youngest of the Scotch Universities, is at once the largest and most celebrated of all the seats of learning in Scotland.

UNLIKE the other Universities of Scotland which were ecclesiastical in origin, being founded by Papal Bulls, the University of Edinburgh can boast of its Protestant and Democratic parentage. To the public spirit of the Town Council and citizens of Edinburgh the University owes a deep debt of gratitude, a debt which it has sometimes tried to forget, but which it can never repay. Town Councils are not, as a rule, credited with much enlightenment, but Edinburgh appears to have been singularly fortunate in this respect, that, whatever its shortcomings in other respects may have been, its Council has always been alive to the value of providing a sound education for the people. He must be poor indeed who cannot obtain a University course in Scotland and take a degree if he so wishes it.

THE English Universities are for the titled and the rich; the Scotch Universities are for the untitled and the poor. But the democratic character of the latter prevents that higher culture which can be obtained alone at the Universities of Oxford and Cambridge. The want of a collegiate training is the weakness of the Scotch University system, and it is a pity that all previous attempts to remove the deficiency have failed. Without bursaries to assist the needy no collegiate system can succeed, for all men "*must live*," though with Talleyrand there are some who "*may fail to perceive the necessity*."

THERE are men now holding high and noble positions in the world of science and of literature who were hard at work at manual labour while attending the classes of the University. To mention any of these names would be invidious, but Edinburgh can boast of many such among her children.

OF course in the general desire to see and be seen there is some irritation as to the distribution of tickets. In some cases this irritation has been relieved by an eruption of epistolatory growls in the columns of our local contemporaries; still it may be said on a little reflection, that taking all the difficulties to be surmounted by the different committees, no one has any very great reason to complain.

ALL credit must be given to the Students' Representative Council for the good work they have done. Formed scarcely three months ago, the Council has worked wonders in the general *morale* of the students, and a Lord Rector can now deliver his address without providing lint and bandages for his head, or a ward in the Infirmary.

SOME of the cards of admission to the several receptions are works of art, and will form suitable *souvenirs* of the Tercentenary celebration. The card issued by the Town Council contains views of the Old University and New Medical School, of Holyrood Palace, Heriots Hospital, St. Giles' Cathedral, the supposed scene of the religious fervour of the notorious Jenny Geddes of pious memory, and the Scott's monument. A medal has also been prepared for the occasion by Messrs. McKay and Cunningham, the centre of which is occupied by the University arms upon a shield standing out in bold relief from a pentagonal recess, within which thistles twine in the interstices and ornament the plane surface. This is surrounded by a broad band, bearing the following inscription: "*Universitas Academica Edinburgensis*." The reverse side carries a massive border, divided into four panels, and ornamented with delicately-modelled thistle wreaths in high relief. The centre bears the following inscription: "*Universitas Academica Edinburgensis, Annus Trecentessimus feliciter exactum celebrat. A.D. MDCCCLXXXIV.*"

AN interesting plate of the laying of the foundation stone of the Old University, with full Masonic honours, has also been published by the enterprising firm of W. Cruckshank, Elder Street. As everybody is a Mason in Scotland, this old print should command a large circulation.

It is rumoured that in 1905 the Extra-Mural School will celebrate its four-hundredth birthday, and that the secretary of the school is beginning to prepare for the auspicious event.

THE poems supposed to have been rejected by the University authorities have been published. For the general public they may lack interest, but those who know anything of the University will appreciate some of the clever skits which the pamphlet contains. "*Mae Mater*," "*Pods of Pease*," and the "*Piamater*," the last on the lines of Longfellow's "*Hiawatha*," are perhaps the best, but the charm of the volume consists in the sapient criticisms of the August Senatus.

Literature.

HOSPITAL MANAGEMENT. (a)

HOSPITAL management is a subject of vast importance in the present day, and hospital reformers have paid much attention to the matter of late. The Council of the Social Science Association who, on several occasions have brought the subject into public notice, at the Dublin meeting in 1881 adopted as one of the questions for special discussion in the Health Department the following:—"Is it desirable that hospitals should be placed under State

(a) "Hospital Management," being the Authorised Report of a Conference on the Administration of Hospitals, held under the Auspices and Management of the Social Science Association on the 3rd and 4th July, 1883. Edited by J. L. Clifford Smith, Secretary of the Association. London: Kegan Paul, Trench & Co. 1883.

supervision?" At this meeting a very interesting and instructive paper was read by Mr. Henry C. Burdett, and at the close of the discussion that followed a resolution was unanimously passed recommending the Council of the Association to petition the Crown in favour of the appointment of a Royal Commission of Inquiry. The subject was again put down for discussion at the next Congress of the Association which took place at Nottingham in September, 1882, the question being "What reforms are desirable in the administration of hospitals?" At this meeting a paper was read by Dr. Gilbert Smith, assistant physician to the London Hospital. The discussion which followed the reading of this paper resulted in the passing of a resolution calling on the Council to continue their exertions to obtain a Royal Commission to inquire into the general management and administration of metropolitan hospitals.

A conference was held on the subject of hospital reform in the Hall of the Society of Arts, London, under the presidency of Sir T. Fowell Buxton, Bart., on the first day, and of Mr. Francis S. Powell on the second, on the 3rd and 4th of July, 1883. To this meeting special invitations were issued to nearly every hospital, dispensary, and convalescent institution in the United Kingdom asking them to send representatives to take part in the proceedings. The meeting was a great success. Fourteen papers were contributed on the various divisions of the subject, useful and instructive discussions followed which with the papers mentioned are embodied in the work before us. At the end of the conference a resolution was passed asking again for a Royal Commission of Inquiry and the appointment of a Committee of Hospital Managers to consider what steps should be taken to secure combined action among hospitals. All interested in the subject of hospital reform should procure this work without delay.

ST. THOMAS'S HOSPITAL REPORTS, 1882. (a)

We are very pleased to notice this volume, the twelfth of the new series of Hospital Reports. It contains some very valuable contributions of the staff and others, together with the Statistical Reports of the Hospital by the medical and surgical registrars to December 31st, 1882. It also contains a general index of all the reports from 1870, when the new series commenced. It is edited by Dr. Seymour J. Sharkey and Mr. Francis Mason, F.R.C.S.

SELECTIONS FROM THE CLINICAL WORKS OF DR. DUCHENNE (DE BOULOGNE). (a)

THE New Sydenham Society may well be congratulated on the appearance of such a valuable work in the English language. Duchenne's world-wide reputation on the subject of nervous diseases rendered it necessary that his life-long labours should be extensively known among English students and practitioners. The work before us has been ably translated, edited, and condensed by Dr. G. V. Poore, who commences by giving a short sketch of the life and work of Duchenne. A list of Duchenne's works are also given, fifty-seven in number, and then follow the contents divided into thirty chapters, with general index at the end. To specify any particular chapter would be out of place as every page teems with valuable information regarding the subject in hand. After a careful perusal we strongly recommend it to those requiring an extended knowledge of the graver forms of nervous and paralytic lesions, and no medical or professional library could be considered complete without a copy of this valuable addition to English literature.

Royal College of Physicians of London.—At a special meeting of the College, on April 7th, the following business was transacted:—Sir William Jenner, as President, having alluded in very feeling terms to the death of the Duke of Albany, and of the interest he took in the affairs of the College and of the medical profession in particular, proposed that addresses of condolence be paid to the Queen and the Duchess of Albany. This was carried unanimously.

(a) "St. Thomas's Hospital Reports, 1882." New Series, edited by Dr. Seymour J. Sharkey and Mr. Francis Mason. Vol. XII. London: J. and A. Churchill, New Burlington Street. 1883.

(a) "Selections from the Clinical Works of Dr. Duchenne (de Boulogne)." London: H. K. Lewis.

The date of the annual Harveyian Oration was then fixed for St. Luke's Day (October 18th), for the future, the day on which it used to be delivered, and on which Harvey's remains were consigned to their new resting-place. On the subject of the coming election to the Fellowship, a by-law was enacted postponing the election of Fellows to the last Thursday in May. The report of the Pharmacopœia Committee was next adopted, and the report of the Medical Bill Committee received, and ordered to be printed on the next summons. A by-law to appoint additional examiners, and another for the appointment of two Vice-Presidents, were enacted. The President delivered his annual address on the expiration of his year of office and on re-election. Dwelling upon the events of the past year, he referred to the Bower and Keates case as one of special interest to the profession at large. Owing to the initiative of the College, and the interview had by its President in conjunction with the President of the Royal College of Surgeons with the Home Secretary, the profession were now assured that no prosecution by a patient could in future be undertaken by the Public Prosecutor without the facts had previously been submitted to some member of eminence, and who should determine that there was sufficient ground for such prosecution. The address concluded with an obituary notice of Fellows.

Royal College of Surgeons of England.—The report of the Museum Committee in reference to the appointment of a new conservator was adopted. It was recommended that the salary should be £600 per annum, with residence to be provided in the vicinity of the College. Advertisements will be published in the medical journals next week, and in the daily papers on the 19th instant. Candidates are invited to send in applications by the 3rd of May. In consideration of Mr. Trimmer having completed twenty-five years of service to the College, and in recognition of his arduous duties in connection with recent medical legislation, the Council resolved to present him with a sum of £500. The Jacksonian Prize was awarded to Mr. Frederick Treves for the best essay on the "Pathology, Diagnosis, and Treatment of Obstruction of the Intestines in its various forms in the Abdominal Cavity." A letter from the Home Secretary was read stating that in future no prosecution in which any member of the medical profession is concerned will be undertaken on behalf of the Crown without careful preliminary inquiry. A letter from Mr. Tweedy, directing attention to the 7th Section of the Charter of the 15th Victoria, relating to members of Council who at any time after their election may cease from the *bona-fide* practice of their profession, was referred to the President and Vice-Presidents to consider and report thereon to the Council at its next meeting. It was resolved that the recommendations passed at the recent meeting of Fellows and Members should be taken into consideration at the same meeting, to be held on May 8th. Sir James Paget gave notice that he would at the ensuing meeting move a vote of thanks to Dr. A. Farre for his presentation to the Museum of a large and valuable collection of water colour and other drawings left by his father, the late Dr. J. Richard Farre.

Notices to Correspondents.

63 CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a *distinctive signature or initials*, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

LOCAL REPORTS AND NEWS.—Correspondents desirous of drawing attention to these are requested kindly to mark the newspapers when sending them to the Editor.

READING CASES.—Cloth board cases, gilt-lettered, containing 26 strings for holding each volume of the *Medical Press and Circular*, may now be had at either office of this Journal, price 2s. 6d. These cases will be found very useful to keep each weekly number intact, clean, and flat after it has passed through the post.

MR. JONATHAN HUTCHINSON ON THE PNEUMATICS OF VOICE.

To the Editor of the MEDICAL PRESS AND CIRCULAR.

SIR,—In the valuable course of lectures by Mr. Hutchinson now appearing in your journal, the author gives 580 lbs. as an approximate total pressure over the surface of the chest, adding, "the muscular power to overcome this could not have been less than 1,000 lbs."

As the test of a chain is its weakest link, so the test of imprisoned air is the aperture of the vessel. May I be permitted to ask whether any physiologist has yet been able to show that the true vocal cords can alone resist the greatest pressure that can be brought to bear upon them from below—the false cords being removed? I want a proof that the true cords can, and do alone, bear the brunt of the whole chest pressure.

In the index of Mr. Browne's work my theory or hypothesis is denounced as resting on "garbled quotations" from Dr. Wyllie. My quotations, both in the original articles in your paper (1-73), and in their re-issue, were word for word as Dr. Wyllie wrote them. Now I contend that Mr. Browne or some other physiologist who disagrees with me in my physiological and physical explanations is bound to supply me with a more rational explanation. May I inquire if such be forthcoming?

Edgbaston, Birmingham.

Yours, &c.,
CHARLES LUNN.

DR. DICKENSON.—Caffein is a decided diuretic and heart stimulant, when administered in the form of citrate. It is attaining considerable reputation among physicians.

DR. CORNISH.—It is best, if possible, to avoid the employment of mercury altogether in the case of children; but if this drug is specially indicated in the case you describe, the following prescription may be resorted to:—

R Hyd. c. cret., gr. xxx;
Pulv. Doveri, gr. vi. M.

Divide into twelve powders, of which one is to be taken as occasion demands; and not oftener than is absolutely necessary.

THE CORK STUDENTS AND THEIR GRIEVANCES.

To the Editor of the MEDICAL PRESS AND CIRCULAR.

SIR,—Your article under the above heading in your issue of April 2 is hardly fair to the students. Allow me, as an old student, to point out that the question as to whether the fee is high or low is beside the mark. A man enters under the condition that two courses in practical anatomy are sufficient, and to be virtually compelled to pay for a third is not fair. If the fee is small it is no reason why a student should not retain it. You say: "In any other of the schools in Ireland than those of the Queen's Colleges they would be required to pay the prescribed fee for every course of instruction they might please to take." Are you not aware, Sir,—1st. A student can pay an entrance fee in Dublin, and if he does not require the certificate afterwards he need not pay for it; 2nd. In Cork, a student must pay the full fee (for any lectures he intends taking out) at the commencement of the session. In my time in Cork great dissatisfaction prevailed among third and fourth year's students, as they were not allowed to enter the dissecting-room unless they were taking out the course of practical anatomy; and this exclusion is equivalent to compelling the students to take out an additional course of anatomy, the certificate of which is unnecessary.

As to whether a student has a right to interfere in politics, in England, the medical papers are frequently crying out that medical men do not take sufficient interest in politics; but then the Queen's students took interest in the wrong side, which makes all the difference.

Yours, &c.,
J. W.

April 4, 1884.

A.M.D.—The usual period at which children are weaned is at eight months old, and unless exceptional circumstances indicate a different course the rule should always be observed; not less on the mother's account than the infant's.

CEPHALIC.—You will find the paper in full in the volume of Transactions of the International Medical Congress devoted to Medicine.

DR. CARPENTER.—The regulations to which you refer have been in force several years, and have been found to work satisfactorily. Any suggestions for improvement would, however, we feel sure, be carefully considered, if communicated to the right quarter.

DR. O'FLYNN.—The bona-fides of the statement is beyond all question. As to the justice of the proceeding we prefer not to express an opinion until we are in possession of further evidence.

MR. LAWSON.—You have not been guilty of any impropriety, as you term it, in asking us to recommend a particular hospital for you to enter at. Before doing so, however, you had better supply some particulars as to the work you have already done, some schools being better adapted than others for the prosecution of earlier studies of the curriculum. The place you name occupies a very good position, but not by any means the highest among metropolitan schools of medicine. For practical work, however, it is very good.

C. T. G.—A number of letters have been received on the subject, but until the authors of the scheme are prepared with some definite plan of proceeding, it is useless to discuss the details of arrangements which may or may not meet with their approval.

MR. MAY.—The paper is destroyed.

W. H. LYON.—The Medical Bill, if passed into law, will not in any way alter the status of a qualified man. He will retain all his privileges, and will not be required to pass any examination.

ONE IGNORANT.—The question hardly needs a reply. Of course the conduct referred to would be criminal, and might be punished by imprisonment.

THE INFLUENCE OF DIET ON DISEASE.—A QUERY!

To the Editor of the MEDICAL PRESS AND CIRCULAR.

SIR,—May I ask through your columns for information regarding the cure of disease by means of a non-flesh diet? Will brother practitioners who have received any benefit themselves from the disuse of flesh, or who have seen cases of disease recover by the disuse of flesh, kindly send me an account of such? Or if any have seen disease produced by the adoption of a vegetarian diet, will they kindly send me an account of it? Any other facts or observations with regard to food will be thankfully received.

Yours, &c.,
84 Claremont Sq., London, N., T. B. ALLINSON, L.R.C.P. Ed.
April 8, 1884.

DR. WOLFE (Glasgow).—We hope to insert your paper in our next.

MR. ALEXANDER WATT (Annville).—Thanks for your offer; we do not accept articles on medical subjects by others than members of the profession. See our reply to Mr. Gerner in last number.

INTESTINAL CONCRETIONS.

To the Editor of the MEDICAL PRESS AND CIRCULAR.

SIR,—My remarks about the phosphatic nodules exhibited by Dr. Ball at the Academy of Medicine in Ireland, Feb. 29, and reported in your last issue, have, I fear, been misunderstood. What I said was that they were undoubtedly mineral, not of animal, origin, that the original mineral, whatever it was, had undergone complete metamorphosis, and, strange to say, been replaced by phosphate of lime, an alteration which was quite novel, and not easily accounted for. It appears likely that, as suggested since by Prof. O'Reilly, the primitive mineral was sulphuret of iron. Prof. O'Reilly exhibited a fine collection of similar concretions from Podolia lately, at a meeting of the Geological Society, at the Royal Dublin Society.

20 Harcourt Street, Dublin,

April 10, 1884.

Yours, &c.,

W. FRAZER.

DR. A. (Sunderland).—We hope to refer to the subject in our next.

A BONA-FIDE STUDENT.—We are glad to have been of service, and shall be happy to follow up the subject if necessary.

MR. BERRY (Wigan).—The subject has occupied considerable attention of late; we shall be happy to find space for your paper.

DR. CLIFFORD ALLBUTT is thanked for his note.

Meetings of the Societies.

THURSDAY, APRIL 17TH.

HARVEIAN SOCIETY.—At 8.30 p.m., Dr. D. B. Lees, Note on a Form of Diarrhoea in Children.—Dr. T. Robinson, On Acne Rosacea.

FRIDAY, APRIL 18TH.

CLINICAL SOCIETY OF LONDON.—At 8.30 p.m., Dr. de Havilland Hall, Sequel to a Case of Perichondritis of the Larynx.—Dr. Percy Kidd, A Case of Tubercular Tumours of the Larynx.—Mr. Harrison Cripps, Cases of Excision of the Rectum for Cancer.—Dr. Angel Money, A remarkable Case of Tubercular Meningitis.

Vacancies.

Alton Rural Sanitary Authority.—Medical Officer of Health. Salary, £80 per annum. Applications to the Clerk of the Union, Alton, Hants, by April 23.

Birmingham General Hospital.—Resident Surgical Officer and Resident Registrar and Pathologist. Salary attached to the former, £130 per annum, with board and residence; and to the latter, £100 per annum, with board and residence. Applications to the House Governor by April 26.

Brompton Consumption Hospital.—Resident Clinical Assistants. Board and residence, but no salary provided. Applications to the Secretary by April 19. (See advt.)

Chatham, St. Bartholomew's Hospital.—Assistant House Surgeon. Salary, £100, with board, &c. Endorsed applications to be sent in by May 1.

Coombe Hospital, Dublin.—Assistant Master. Applications to Master, or at Coombe Hospital.

Cheshire County Asylum, Macclesfield.—Medical Superintendent. Salary, £500, with furnished house, &c. Applications to Mr. A. C. Procter by May 3.

Appointments.

EDIS, A. W., M.D. Lond., F.R.C.S., Obstetric Physician to the Middlesex Hospital.

HASLAM, G. J., M.D., Honorary Physician to the Hulme Dispensary, Manchester.

FUGHR, T. W. O., M.B. Lond., M.R.C.S., Honorary Medical Officer to the Liverpool North Dispensary.

STARTEIN, J., M.R.C.S., Honorary Consulting Surgeon to the Sheffield Public Hospital for Skin Diseases.

WESTBY, G., M.K.Q.C.P.I., L.R.C.S.I., &c., Honorary Assistant Surgeon to the Liverpool Hospital for Skin Diseases.

WHOLEY, T., L.R.C.P. Lond., M.R.C.S., Resident Accoucheur to the London Hospital.

Births.

BLACKETT.—April 7, at Wangford, Suffolk, the wife of E. Ralph Blackett, M.D., of a daughter.

Marriages.

BOSWELL—HORNE.—April 12, at St. George's, Bloomsbury, John Irvine Boswell, M.R.C.S., L.R.C.P., of Faversham, Kent, to Ellen Elizabeth, only daughter of Edgar Horne, of 46 Russell Square, London, W.C.

MORRIS—BAGG.—April 9, at St. James's Church, Brighton, J. Morris, M.R.C.S.E., to Selina Mary Ann, daughter of the late W. Bagg, Esq.

SMITH—STEERS.—April 9, at All Saints' Church, Dublin, Alfred F., son of H. J. Smith, M.D., F.R.C.S.I., of Ballybrophy, Queen's Co., to Edith Mary, daughter of the late T. Steers, Esq.

Deaths.

BEST.—April 6, at Billston, Henry Dewes Best, M.R.C.S., J.P., aged 51.

CHOWN.—April 4, at Terowie, South Australia, Joseph W. Chown, M.B., late of Bloomsbury, London, aged 32.

NIVEN.—April 6, at Udny House, Teddington, after protracted illness, David Graham Niven, F.R.C.S., aged 72.

A Course of Lectures

Delivered at the London Hospital during February, 1884.

By JONATHAN HUTCHINSON, F.R.C.S., F.R.S.,

Emeritus Professor of Clinical Surgery at the London Hospital; Consulting Surgeon to the London Hospital, and to the Royal London Ophthalmic Hospital.

DISEASES OF THE NERVOUS SYSTEM OF SYPHILITIC ORIGIN.

In a former lecture, the lesions of visible characters produced in the skin through presence of syphilitic virus in the constitution, have been described, and it has been there shown how exceedingly varied such manifestations may be. Accordingly, therefore, the effects that result from the disease are likewise of the most various description in respect both to duration and persistency. Occasionally they cease spontaneously; and in lupus we have a good example of the serpiginous manner in which a syphilitic lesion progresses, and at the same time of the tardy development which such affections may exhibit, some cases lasting for as long as twenty years. A similarly slow procession of events is evidenced in syphilitic diseases of the nervous system, the virus having power to exert its specific action in any part of the body where nerves occur embedded in connective tissue. This class of diseases includes practically every variety, in point of time and intractability of cure; and in some cases the hold they take is of so tenacious a description that they are all but incurable under every form of treatment. In this connection, and as assisting to determine the character of the mischief set up, it may be taken as a general statement that the more speedily that the peculiar phenomena of the disease manifest themselves after the occurrence of infection, the more quickly will they fade away; and, on the other hand, the longer the diseased condition is in making its appearance after primary inception of the syphilitic taint, then the more persistent will it be; and a further general statement may also be made, to the effect that all the tertiary symptoms of syphilis have a distinct tendency to

progress so long as they remain uninterfered with by treatment.

The pathological processes initiated in the nervous system as a consequence of constitutional infection by syphilis, may take any one or more of several different forms, and for convenience of description they can be classed in certain well-marked groups, as follows:—

I. *Neuritis*.—This may be evidenced in the shape of a gumma at one point of a nerve, disorganising by its presence the whole or only a part of the structure in which it is found; or it may show itself as a spreading inflammation of the nerve trunk. Such syphilitic neuritis is sometimes found attacking two or more entirely different nerves at one and the same time; and a case in point was mentioned by Mr. Hutchinson as having occurred in his own practice. In this instance several separate cranial nerves were simultaneously the seat of development of gummata.

II. *Inflammatory Disorganisation of Central Parts of the Nervous System*.—In this variety of lesion any portion of the structures implicated may become the seat of changes, which will be discovered, sometimes on the surface of the brain, at others, in the nuclei of cells; and again in other regions of the central element.

III. *Inflammation of Peripheral Organs*.—Under this heading are to be included the syphilitic inflammatory affections manifested in such parts as the eye, ear, ganglia external to the centres, tactile corpuscles of the skin, &c. The condition of things produced in leprosy affords a good illustration of what occurs when the end organs of the skin become the seat of inflammation, and as showing the succession of events, it may be accepted as showing that which occurs in the states under consideration.

IV. *Meningeal Inflammations*.—Inflammatory changes may occur in the arachnoid, pia mater and dura mater, in which an increase of vascularity then takes place accompanied by thickening of greater or less amount. In some cases the formation of gummata may also occur in these situations.

V. *Inflammation of Bones*.

VI. *Inflammations of Arterial System*.—In this class of cases the inflammatory action results in the formation of a

ragged ulcer on the internal coat of an artery, and consequent on this, and the coagulation it induces in the blood which is in contact with the injured wall, a plug of clot is formed, whereby the lumen of the vessel becomes occluded at this point of its course. Arterial disease of this description is most commonly encountered in the brain, disease of which organ is very frequently caused through thrombosis of some one or more of the cerebral arteries, resulting from syphilitic injury to their coats.

In recent times there has arisen a broader view of the etiology of these arterial affections than was primarily held, when they were regarded as being invariably initiated during the tertiary stage of the disease. Now it is recognised that, in comparatively early stages of syphilis, examples of almost any known neurosis may be encountered; but it is also true that these conditions, and those as well which appear during the secondary stage, are only transitory.

Neuritis may occur in any nerve as the result of syphilitic infection; but the fifth cranial is that which is most often found to be selected by the disease; and many cases of this description have been met with by Mr. Hutchinson in the course of his experience. As a rule, it is the middle or late periods of the syphilitic infection at which the nerve lesion becomes manifested, and from three to four years after the primary symptoms have subsided. At this time neuralgic pains of unusual severity are generally experienced, and directs attention to the area of distribution of the fifth; and subsequently all the parts supplied through it become paralysed, though in some cases only incomplete loss of sensibility may be induced. In cases, however, in which disorganisation of the nerve occurs at the Gasserian ganglion, then anaesthesia of all parts supplied by the fifth results, with the exception of a small part of the parotid region, the innervation of which is independent of the fifth. At the same time, the muscles of mastication become powerless in so far as they derive motor filaments from the fifth pair. Pain ceases to be felt when complete disorganisation of the trunk has taken place, its usefulness as a conductor of impressions being thereby destroyed.

These cases are almost invariably unilateral in character, as are the lesions following tertiary syphilis as a rule, whereas secondary lesions are commonly symmetrically distributed. Mr. Hutchinson said he himself had only seen two cases of paralysis of the fifth nerve in which the injury was symmetrically distributed on both sides of the head. One of these cases was that of a gentleman who came under treatment for ophthalmia. On examination it was discovered that complete anaesthesia existed over all parts supplied by the fifth nerve, and a syphilitic origin for the mischief could be made out. The eye was ultimately excised without the employment of an anaesthetic, and the operation was wholly a painless one. In the second case also an eye was excised under very similar circumstances and without an anaesthetic, the patient being a young woman.

Prognosis in cases of syphilitic affections of the fifth nerve is decidedly favourable, and even when atrophy is pronounced, and has existed for as long as twelve months, it is highly probable that rigorous anti-syphilitic remedies may suffice to restore the efficiency of muscles, nerves, &c., which have undergone atrophic changes. In some cases good results have been obtained, notwithstanding that an excessive degree of muscular atrophy had ensued; and, in fact, we should scarcely ever despair of securing benefit from treatment in all cases where the fifth nerve is directly influenced as a consequence of syphilitic infection. Probably in every improved case more or less disorganisation of structure persists, even after restoration of its function to the nerve; but in any case it is not of any great amount.

In the case of the gentleman referred to above, the excision of the eye was followed by affection of the fifth nerve on the side opposite to that already anaesthetic; but, as described, under anti-syphilitic remedies a complete cure was brought about, and though the operation was

performed fifteen years since, there has been no recurrence of any symptoms pointing to syphilis; from which it is clear that complete cure of the disease in its tertiary stage is quite possible to be attained.

In point of frequency, syphilitic disease of the portio dura is much less often encountered than similar affections of the fifth pair of nerves; but the reason for the preference shown for the latter has never yet been satisfactorily explained. Mr. Hutchinson has seen only a few instances in which the former has been selected by the disease; and in one of these both sides of the head were affected. In the same way, too, the portio mollis of the seventh pair is affected only in exceptional cases of acquired syphilis, although when such affection does take place its manifestations appear at a comparatively early date, usually about the second year, and the type it exhibits is one of great severity; so much so that the patient becomes subjected to absolute deafness as a consequence. Threatened deafness is a common symptom in these cases, but active administration of mercury sufficiently early may suffice to ward off the injury to hearing. In this connection it is interesting to note that notwithstanding the rarity of deafness in persons who have acquired the syphilitic taint, it is nevertheless frequently encountered among those who have been subjected to the disease through inheritance. It should be remembered also that, as a rule, in such cases the deafness results from implication of the nervous apparatus of hearing, and by no means of necessity implies that the mechanism of the ear itself has undergone injury.

The motor nerves of the eye are very often found to be affected by syphilitic changes, and the occurrence of ptosis would of itself suggest that a cause of this nature was to blame for the condition of the organ; and its influence may then be found to extend over either any single nerve of the series or over any group comprised within it.

Under circumstances occasioning the kind of injuries now being considered, it is possible that any nerve trunk whatever may become the seat of inflammatory alterations; and the difficulty attending on examination with a view to diagnosis will be considerably increased in those instances where the part affected is far removed or hidden from direct observation, as, *e.g.*, the pneumogastric. The nerves of the palate have been found affected by Mr. Hutchinson; and as a general conclusion he expressed the opinion that there is not any nerve which may not become liable to those changes induced by the action of the influence exerted by the presence of syphilitic poison in the system.

(To be continued.)

ON AN OPERATION FOR THE CURE OF DETACHMENT OF THE RETINA.

By J. R. WOLFE, M.D., F.R.C.S.E.,

Senior Surgeon to the Glasgow Ophthalmic Institution; Lecturer on Ophthalmic Medicine and Surgery in Anderson's College.

DETACHMENT or separation of the retina is caused by the effusion of serum between that membrane and the choroid coat. It may, therefore, be called subretinal dropsy. This condition may be induced either by disease or by injury; in either case the fluid is exuded from the choroid. The vascular tissue secretes an abundance of serum which accumulates behind the retina and pushes that membrane forwards so that, in some cases, it may even be seen by the naked eye in the shape of a bluish mass floating in front of the focus of the dioptric system. That pathological condition, therefore, is essentially a disease of the choroid, although in some cases it may be complicated with opacity of the vitreous, and in a further state of development may lead to morbid change of the lens

(a) Read before the Glasgow Medico-Chirurgical Society, April 4th, 1884.

and the other deep structures. The ophthalmoscope enables us to discover its existence from the initial stage, watch its progress, and determine with precision the site of the lesion. The symptoms are dimness of vision, followed by interruption of the visual field, i.e., the patient sees when looking in one direction, but when looking in another a cloud seems to intervene between him and the object, and hence when the effusion continues to accumulate vision is entirely abolished. This brief statement with regard to the pathology and site of the affection shows the difficulty of the problem how to deal with it. Considering that the disease is situated behind the posterior pole of the eye, behind the lens and vitreous humour, it has been generally thought that that region is inaccessible, and beyond the reach of surgical interference. The late Von Graefe tried an operation in which he introduced a needle through the sclerotic into the detached mass, ruptured it, and allowed the serum to disperse into the vitreous and there to be absorbed. Sir William Bowman was the only one who did the same operation, for I am not aware that in this operation Von Graefe has found any other imitator. The results were far from encouraging. The present state of the science in this department will be seen from the report of the meeting of the Ophthalmological Society of France held on January 28th, 1884. At that meeting M. de Wecker, who, bye-the-bye, tried some operations of his own, stated that he failed in every operative attempt, and that he had lately found useful the application of strong revulsive measures by the repeated application of the cautery (*pointes de feu*) upon the surface of the sclerotic, and M. Galezowski recommended putting the patient in a horizontal position for several months without interruption for a single instant. In other words it is a desperate affair. We must try something, and we may well ask "*et après*," &c., what becomes of the eye after the sclerotic has gone through the baptism of fire, and what becomes of the patient after he has been lying upon his back for several months without a moment's intermission? I merely mention this in order to show what these celebrated ophthalmologists think of the chance of ever obtaining a cure for detachment of the retina. But I cannot help asking also if they have ever tried the operation which was introduced by me in 1878. Repeated successful cases from my clinique have been published in the *Annales d'Oculistique*, and in other Continental journals. My first case I showed to this Society, and I shall have the honour this evening to submit another operation for detachment of the retina which I have performed on 21st February, i.e., fifteen days ago. Before submitting the patient to your inspection, permit me to say a few words with regard to the principles upon which that operation is founded, and how my attention had first been directed to its adoption. I have very frequently observed in laceration of the sclerotic with prolapse of the vitreous, how easily we can repair the injury by simply bringing the cut or lacerated edges together by a ligature.

Here is a case in point:—Hugh G., a rivetter, who lost his left eye seven years ago, had the misfortune to injure the other eye also with a rivet, at the beginning of last month. The injury consisted of laceration of the cornea and sclerotic, and produced opacity of the lens. This you will see from the black mark extending a quarter of an inch into the sclerotic at its junction with the cornea. I have extracted the lens and brought the edges of the scleral wound together with a ligature applied to the corresponding portion of the conjunctiva, and you can satisfy yourselves as to the result obtained. The eye is useful and as good as you can expect after the removal of the cataract ten days ago. The same accident frequently happens to other portions of the sclerotic. Now, it occurred to me with regard to sub-retinal dropsy, that, if we could dissect the soft structures from the sclerotic, and rotate the posterior pole of the eye forward, there is no reason why we could not tap

the eyeball, remove the effused fluid from behind the retina, in the same manner as we do to the thorax, abdomen, or any other cavity.

The author showed the instruments used for the operation, and described his operative procedure in the case.

Sylvester Hammel, æt. 38, tailor, applied for advice at the Glasgow Ophthalmic Institution on 5th September, 1883. About three years before he had lost the sight of his right eye. The cornea of that eye is hazy, the lens is opaque, and the pupil undilatable being fixed by posterior adhesions, tension—the blindness of that eye is complete. He can but slightly distinguish the flicker of a lamp held at the temporal side, but the luminous perception is lost in front, and at the nasal side. Viewing, therefore, the cataractous condition of that eye with so many complications, it must be considered as absolutely incurable. The left eye, however, had been apparently free from disease till two years before, when it commenced to be affected and gradually became worse. On the day of admission he was quite blind and had to be led. That eye also has a nebulous cornea, but the pupil acts freely and tension is normal. The ophthalmoscope revealed a detachment of the retina and the presence of large flocculi floating in the vitreous. The light of a lamp held in front of the eye could scarcely be perceived by the patient in any direction. The condition of that eye was therefore pronounced also unfavourable, and I was reluctant to risk an operation upon it. On February 3rd the patient returned, most anxious that something should be done for that eye, and as his condition could not, at any rate, be made worse, I yielded to his solicitations.

February 14th.—The operation was performed under chloroform. The conjunctiva and sub-conjunctival tissues having been opened, the sclerotic, which had thus been laid bare, was punctured in the posterior hemisphere of the globe, in the line of the vertical meridian. Instead of the gush of fluid which generally follows the withdrawal of the lance, only small quantities of serum came each time the flap-probe was introduced. The operation was concluded by applying a silk ligature to the wound, and closing the eye with adhesive plaster, lint, and a bandage. After five days the ligature was removed; vision then had so far recovered that the patient could see faces, count fingers at a distance of about eighteen inches; but the vision was limited to the outer part of the field, the inner being still a blank. The ophthalmoscope showed the existence of a detachment at the lower and outer part of the fundus. Tension being normal, I determined to repeat the operation in the region indicated. This was done on 21st March. A section was made in the space between the external and inferior recti muscles, and the eyeball being rotated upwards and inwards, the lance was introduced through the sclerotic and the posterior hemisphere of the globe corresponding to the site of the detachment. This time there was a considerable gush of serum on the withdrawal of the lance. No ligature was applied to the wound; the lids were only closed with adhesive plaster, lint, and a bandage.

On examination four days after the operation, the field of vision was found complete. The patient could make out Snellen's type, No. 20, at fifteen inches distance, and read No. 16 of Jager, and could tell the time to a minute on a watch and follow accurately with his finger the movements of a small seconds pointer. This being the fifteenth day since the operation, you will satisfy yourselves that his acuteness of vision is very satisfactory. In this case there is no room for doubt, inasmuch as I have only just the other day learned that the patient, previous to admission, had attended another eye infirmary, and his card from that hospital, dated July, 1883, is marked: "irido-choroiditis and separation of the retina." Indeed, but for that circumstance which furnishes me with corroborative evidence from an independent source, I should not have

shown the case to this society. The case is also remarkable as being the first in which I ventured to repeat the operation on the same eye.

It is the sixth successful case which I have had since I first introduced the operation. From my first patient I had a letter addressed to me in her own handwriting a year after she returned home, and I am not aware of any relapse in any other cases. I had only one failure, but the eye was soft to begin with, and the issue was a foregone conclusion.

MEDICO-LEGAL INSANITY.

By J. ROCHE, M.D.,

Bombay Medical Service, Retired List; formerly Civil Surgeon, Kotree, Hyderabad, Scinde.

THE gravest consequences to society and individuals attend the right appreciation by the medical profession of cases which bear on the subject of this article. Since I placed before the public through your kind indulgence on the 5th of February, 1873, the case of the murderer Bulchal Shah, who feigned insanity, much progress has been made in the signs, symptoms, and physiology of the insane, but there are many points as yet, so obscure in their pathology as to require close observation, for their full elucidation. Dr. Bucham, of America, the latest and one of the greatest authorities on the subject, has clearly shown that any one test for insanity is practically worthless, and that the mental state can often only be definitely ascertained by an exhaustive study of the patient's family antecedents, personal history, and general condition, and that men who approach the subject with a bias are practically unfit to form a correct opinion when they are retained by one side or another in a contested case. Dr. Skae has advocated that every mental disorder bears a relation to some bodily disease, and Tuke has done some good work in this direction. The absence of any demonstrable bodily affection would not, however, warrant the medical jurist in pronouncing a case to be a feigned one. Dr. Brown, of Canada, lays great stress on the low temperature of the insane. It is a most useful sign, and I believe a most reliable one in the varieties and form in which it is present. In acute mania, caused by fevers, inflammations, injuries to extremities, *mania à potu*, monomania due to diseased state of the digestive or excretory organs, the temperature is raised. In idiocy, pure and simple, *ceteris paribus*, it is not affected. Dr. Brown maintains that when the temperature falls below 95° F. the subject is *non compos mentis*. In this statement I agree with him, without exactly bending myself to the arithmetical figure. I certainly think there is a cold stage produced by any or whatever cause in which the brain and mind are incompetent.

Dr. Sibbald thinks the memory of the insane is good, and that the dissembler affects forgetfulness. My experience is that the memory is boastful rather than good, it grasps only a few of the events that transpire with the insane, which are boastfully flaunted before the inquirer. Dr. Tuke, and others, say the insane never know, or rather never acknowledge, their madness. I must demur to this statement. I recollect whilst one Sunday, some fourteen years ago, when going around a large jail at Poonah with the superintendent at the time—Dr. Davidson—I casually entered the lunatic department, and on inquiring of the inmates "What are you here for?" the reply from several was "dewanee," "dewanee," (we are mad). The fact astounded me somewhat, and I questioned about a score, and there was only one who would not reply at all, and who was incapable, in fact, of comprehending. It is the most common imputation by the insane that somebody is maliciously charging them with insanity. The disproportionate increase in the pulse on changing from the recumbent to the sitting, standing, and walking conditions, is present in all cases outside the idiotic. I have

given my reasons for believing it to be a most valuable indication in the article of February, 1873. It must not be understood that it is confined to insanity, as there is no wider diffused sign of disease. The difficulty of securing the attention, and the marked abstraction of the mind, which is alluded to in Bulchal Shah's case, is exceedingly important. This symptom seems to have great weight in the instance of Gouldstone last year (1883). The wife swore that he frequently seemed absorbed in meditation, and that she could not get him to comprehend or answer her question till it was repeated many times.

To the inexperienced there is no condition can be so easily simulated as maniacal abstraction. If, however, the rule followed in Bulchal Shah's case be observed, and a portion of the sentence of conversation be omitted in the repetition it may be discussed whether the person under inquisition can recall the whole meaning, thereby detecting whether the absence of attention was real or feigned.

Delusions and illusion are mostly constant in their notion in the insane, e.g., if anything give the impression of poison it will be constantly poison. It will not be one time a food or a healing medicine, and another time a poison. If an individual give the notion of a murderer, he will constantly give it. If the delusions of applications attempting to kill are described, these are never transformed into salutary efforts. I have observed these facts exemplified admirably in a lady-monomaniac excited by injury in a constitution nervous and reduced through bad digestion. In the dissimulator, the factors are entirely different. I have touched this subject with sincerity, and an earnest desire to centre the attention of observers on a most intricate and important medico-legal question, and if I could impress the minds of those members of the profession who will be hereafter consulted in similar grave cases, I would say, reputation is nothing when weighed against life or the welfare of society.

Mount Clarence, Kingstown.

Clinical Records.

CASHEL UNION HOSPITAL.

CASES UNDER THE CARE OF DR. LAFFAN.

Albuminuria and Mitral Regurgitant Murmurs.

Two very interesting cases in which non-organic murmurs of the above class were evidently caused by albuminuria have occurred in my practice. J. B., a stout young woman of red hair and florid complexion, was admitted to my mid-wifery ward in 1880. She was within a few weeks of her confinement. She was completely anasarcaous; the lower extremities, face, abdominal walls, and arms being swelled. The uterine enlargement was excessive, and, as double fetal sounds could not be heard, excessive amniotic fluid was diagnosed. Abundance of albumen was found in the urine, auscultation discovered a mitral regurgitant murmur and the sounds of universal bronchitis. This murmur was constant, and unchanged by position, &c., in character, and so far conveyed the impression of its being organic. Vigorous measures in the shape of cupping, purging, warm baths, acupuncture, and expectorants were used, and under their influence considerable amelioration was obtained. Labour came on in due time, and during its progress she was seized with convulsions. The child, which was dead, was delivered by the forceps. The treatment was continued perseveringly for weeks, and she ultimately, but not for months, got rid of not only albuminuria and dropsy, but also of her regurgitant murmur. She has since been delivered of a second child, and has again and again been examined by me with the result of demonstrating the complete and permanent restoration of the affected organs.

No. II.—J. C., æt. 25, was admitted in 1870 for right hemiplegia, with paralysis of right side of face, stricture of urethra, cystitis, and paralysis of bladder. There was a

syphilitic history. The heart on examination disclosed mitral regurgitant murmur. The patient, who is an intelligent man, stated that he had lost consciousness after having overhauled his water for some hours, despite pressing calls to void it at the onset. He stated that he then fell down in a fit, and that he thought that it was brought about by the mischief thus inflicted on his bladder. It is more likely, however, that he confounded cause and effect, and that the apoplectic seizure, with its attendant paralysis, was caused by the syphilitic disorder. The urine contained a copious deposit of albumen. Careful filtration was, of course, employed in view of the cystic admixtures in the urine. The murmur, like that previously described, was as constant as any organic murmur I have ever heard. Neither posture, time, nor other circumstance in the least affected it. Active treatment was employed. The stricture was attended to, and the urethra dilated to normal size. The bladder recovered its tone, and the disorder of its lining membrane disappeared; then albumen ceased to be present in the urine; and, finally, the cardiac murmur vanished. The patient regained complete power and feeling in the affected side. This change was the last in the progressive series, and he left the hospital in perfect health.

Diastesis of Femur.

M., a young girl, æt. 17½, somewhat scrofulous, fell on the ice, 5th February, 1879, and sustained an intra-capsular fracture (diastesis) of the left femur. She did not come under notice until May 5th, when she was admitted to hospital. The usual signs were present, but not till June 15th did she allow the limb to be put in suitable apparatus, which, however, she used to take off from time to time when my back was turned. On July the 22nd, however, fear or persuasion, I forget now which, induced her to alter her course, and for two months a long splint was kept constantly on, at the end of which time union was found to have taken place. There was a shortening of about ½ inch; she was a little lame for some months, but ultimately got perfectly well. The point of interest in this case is that a cure should have been effected notwithstanding the length of time that elapsed from the receipt of the injury until treatment was entered on.

Orbital Abscess.

A. T., æt. 54, a servant, was under my care in March, 1877. Her right eye was exophthalmic. She suffered from excruciating pain, and complained both of sleeplessness and loss of appetite. Previous history: She complained for some three and a-half years before admission, off and on, of a violent pain across the forehead. This was accompanied by sleeplessness, occasional vomiting, and constipation. There was noise in the ear of the side, with flashes of light and double vision in the corresponding eye. Her memory was also impaired. She never received any hurt and never suffered any illness, save from an attack of fever from which she suffered some years previously. The pain would remain away for a couple of months at a time, was of a burning character, and was aggravated at night. I diagnosed abscess of orbit, which I opened on the 19th, when it gave exit to an immense quantity of pus. She remained in hospital for six weeks, but the discharge did not entirely cease till after a period of six months, when she became well.

Special Articles.

EXPERIMENTAL DIPHTHERIA.

It will be remembered that the German Empress some time ago offered a prize for the best study of diphtheria, and that the prize was awarded to Professor O. Heubner for his essay on "Experimental Diphtheria." Of this essay we now propose to give some of the leading features.

Observation of fibrinous exudations on various mucous membranes in various diseases such as dysentery, small-pox, cystitis, &c., had taught that the fibrinous exudation of diphtheria did not represent anything peculiar to the disease, but that other poisons and injuries had the property of being capable of calling forth the peculiar

affection of the mucous membrane. Professor Heubner determined, therefore, to study experimentally the conditions of the origin of the diphtheritic membrane and then the general disease or their relation to each other. He ligatured the bladder of rabbits just above the point of entrance of the ureters, and cut off the circulation of blood within the ligatured parts. Two hours afterwards the ligature was removed and the animal was then killed, within a longer or shorter period after removal of the ligature.

On the first day after removal of the ligature, marked hæmorrhagic œdema was noted, by which the mucous membrane of the bladder was thrown into folds and ridges. Examined microscopically it was observed that the principal seat of the swelling was in the sub mucosa. The blood-vessels of the whole mucous membrane up to just below the epithelium were widely dilated and quite filled with blood corpuscles. Red and white blood corpuscles in great numbers had left the vessels.

If the animal were permitted to live 30-36 hours after removal of the ligature, the œdema was found to have become solid, the epithelium had apparently disappeared; the cells were swollen and the pores only slightly colourable. If the animal lived 48 hours after removal of the ligature, the part presented the appearance of well-marked diphtheria.

One condition is essential to the production of these appearances, the blood stream must be blocked for a time, but not permanently, for if the latter, simple gangrene follows. By temporary interruption of the blood current the tissues are imperfectly nourished, or not at all, in consequence of which, changes take place in the epithelium, which end in its death. But the walls of the blood-vessels are also altered, the blood again streaming in, enters a diseased vascular system, whereby the second condition in the production of artificial diphtheria is afforded, viz.:—the so-called inflammatory exudation. The inflammatory exudation coagulates and becomes necrosed, the whole is now an intimate union or amalgamation of inflammation and necrosis.

Our author now attempted some inoculation experiments with this artificially produced diphtheria, but with only negative results. Thus Bretonneau's membrane, but not Bretonneau's disease, had so far been produced.

He then combined the local diphtheria with a general disease by inoculation of the latter. He first tried the poison of anthrax, and found that the vessels of the parts that had been ligatured were plugged full with the bacilli of anthrax, but that outside the vessels not a single bacillus could be seen. The like was the case when, instead of the poison of splenic fever, the animal was inoculated from a diphtheritic patient. The vessels were filled in this way with micro-organisms which appeared as short rods. Inoculation with particles from the vesical mucous membrane diphtheria, when the local diphtheria was associated with the general affection proved fatal in a very short time. If a piece of healthy mucous membrane from the same animal was employed for inoculation, the animal so inoculated did not die. From this it follows that in these cases in which there is a combination of the local and general disease, the diseased mucous membrane has the power of storing up the poison in large quantity.

If the rods which were found in the vessels of the diseased mucous membrane of those animals in which the local disease was associated with the general affection, had been the diphtheritic poison, they would also have been found in

the vessels of the diseased mucous membrane of diphtheritic patients. This is not the case however. Our author has made whole series of sections, for example, from the uvula, where shortly before the membrane had been present, but he has never succeeded in demonstrating these organisms in the vessels. From this he concludes that the diphtheritic poison has not yet been discovered.

The disease that arises after inoculation of true diphtheria material, Professor Heubner declares to be not true diphtheria, as inoculations of rabbits with the oral secretions of healthy individuals produced, sometimes, malignant oedema, sometimes necrosis, sometimes septicaemia, sometimes progressive necrosis, &c. This must be for the reason that several kinds of low organisms vegetate in the oral cavity; if the tonsillar mucous membrane becomes diseased, and if necrosis of its superficial layer comes on with the formation of a fibrinous exudation, other forms of low life may now develop on the altered tissues, and may drive off the others. If these new forms are now inoculated into susceptible animals, an infectious disease differing from those that arise after inoculation with healthy buccal-mucous is set up, or under certain conditions a mixed form of various infectious diseases may arise.

France.

[FROM OUR SPECIAL CORRESPONDENT.]

THE ATTITUDE OF THE STATE TOWARDS MEDICAL MEN.—

The meeting of the Académie de Médecine was wholly devoted to the reading of the Report of the Commission named to examine the position of medical men specially attached to the institutions for the insane, and to regulate, where necessary, the abuses to which the alienist was hitherto victim on the part of the authorities.

ANEURISM OF THE FEMORAL ARTERY.—The Société de Chirurgie listened with interest to a paper on "Aneurism of the Femoral Artery," read by M. Desprès, which he treated with digital compression, but without success, the aneurism becoming afterwards diffused and occupied the whole of the thigh, even to the popliteal space. The patient, a washerwoman, *æt.* 36, entered the Charité and placed herself under his care. After having duly examined the tumour, M. Desprès decided on tying the artery immediately below the Fallopian ligament. The collateral circulation became rapidly established, and on the fourth day the tumour began to inflame, and in a short time the whole limb increased in volume. Having observed that in one place the tumour showed a tendency to "point," M. Desprès by an incision laid open the aneurism in its entire length and turned out the clots of blood which filled the cavity; blood flowed freely, but was easily arrested by artery forceps, which were placed on both ends of the vessels; ligature of the upper end was tried in vain, and he left the forceps *in situ*, all going on well for three or four days. But, at the end of that period, secondary hæmorrhage took place, and was arrested by the ligature of the deep femoral artery. However, five days subsequently the patient was seized with a rigor, and in forty-eight hours succumbed, presenting all the symptoms of purulent infection. At the autopsy it was found that one of the forceps was placed on the vein. M. Desprès concluded from this case that digital compression aggravates the prognosis of ligature of the femoral artery, and it might be said that it aggravates the prognosis of aneurisms that it does not cure. M. Trelat, in praising the

conduct of his colleague in this difficult case, said that it might have been better to have replaced the forceps by the ligature, and that he could not help thinking that if antiseptic precautions had been used the grave complication to which the patient succumbed might have been avoided. M. Perrin agreed with M. Trelat as to the advantages of antiseptic treatment, and thought that M. Desprès was to blame in not having tied the extreme iliac, which was generally an easy operation. He had in 1870 performed that operation on an officer for femoral aneurism, and it was so successful that the patient was able to rejoin his regiment. Others members followed, and all agreed with the observations of the last named.

THE NEW MEDICAL BILL.—The Commission formed to examine the new Medical Bill voted the first clause, which renders illegal the practice of medicine by any person not provided with the diploma of the doctorate; consequently the title of *officier de santé* is abolished. The second clause, which purposed facilitating the taking out of the diploma of the doctorate by those actually holding the inferior degree was also approved of with a slight modification. Any *officier de santé* of six years' practice can obtain the higher diploma on passing two practical examinations and the *thèse*. The discussion of the third article, which concerned foreign medical men, and Frenchmen qualified abroad, was adjourned to have proof of how French medical men were admitted to foreign degrees. If this Bill pass, there will be but one recognised degree in all the territory of the Republic—that of M.D.

A DISPENSING MISTAKE.—A sad accident occurred in Cherbourg last week. A young girl, who was in the habit of injecting a solution of pilocarpine for an affection of the eyes, went as usual to the chemist to get the prescription made up. On returning, she injected, as was her custom, the solution over the left temple. In a few minutes she was seized with violent pain, and soon expired. An error was committed by the chemist, who, having discovered it, ran to the house of the girl, but she had just expired. He had given aconite for pilocarpine.

Transactions of Societies.

CLINICAL SOCIETY OF LONDON.

FRIDAY, APRIL 18TH.

The President, Sir ANDREW CLARK, Bart., M.D., LL.D., &c., in the chair.

Dr. DE HAVILLAND HALL read a paper, a sequel to a paper read before the Society on April 28th, 1882, entitled

PRIMARY LARYNGEAL PERICHONDRITIS.

The subsequent course of the case showed how untrustworthy negative histories are, as the post-mortem revealed marked syphilitic lesion, so that the perichondritis was almost certainly of syphilitic origin. The patient, a man, *æt.* 25, was admitted into Westminster Hospital on October 9th, 1882, wearing a tracheotomy tube, for the purpose of having his stenosed larynx dilated. The day after his admission painful swellings of the joints and in the muscles developed. These disappeared under the use of large doses of iodide of potassium and the inunction of blue ointment, but the pain and febrile disturbance prevented any treatment of the laryngeal stenosis. In the beginning of February, 1883, the patient left the Hospital, free from pain but very emaciated. He was then lost sight of till July 2nd, when he was re-admitted into the Hospital, suffering from albuminuria and diarrhoea, and he died two days later. The autopsy showed constriction at the junction of the larynx and trachea, the aperture only admitting a No. 12 catheter; above the point of constriction the

mucous membrane was normal; below, thickened, of a dark chocolate colour, and its surface bathed by a layer of yellow pus; the right cricoid cartilage was partially absent. The liver was a marked example of the fatty and lardaceous degeneration, and there were peri-hepatic and peri-splenic adhesions.

The PRESIDENT observed that operations might, under certain circumstances, be succeeded by arthritic changes which entirely cleared up in a short time. The favourable effect exerted over doubtful swellings by iodide of potassium was usually taken to imply either that they were aneurismal or syphilitic in nature; but he considered that it was a perilous proceeding, and instanced a case in point which had recently come under his own observation. It was that of a patient over whom five physicians had been in consultation respecting a tumour, the diagnosis being that it was aneurismal. Iodide of potassium had afforded decided relief, but notwithstanding, Sir Andrew Clark's suggestion that it was of cancerous origin, ultimately proved to be correct.

Dr. HALL said that in his case the swelling was not merely relieved by iodide treatment, it rapidly and entirely disappeared.

Dr. PKECY KIDD on a case of

TUBERCULOUS TUMOURS OF THE LARYNX.

A patient, *æt.* 50, who had suffered from cough, hoarseness, and shortness of breath for eight months, came under observation as an out-patient at the Brompton Hospital in the following condition:—Chest: Signs of consolidation of the upper part of the left lung with complete absence of râles. Larynx normal, with exception of the vocal cords. On the posterior extremity of the left cord was a spherical tumour as large as a small pea. On the corresponding part of the right cord there was a small pinkish prominence. The pulmonary condition remained unchanged for months, scanty, obscure râles being heard occasionally, but more often were absent. There was very slight increase in size of the laryngeal tumour, but the prominence on the right cord gradually assumed the proportions of a tumour which, like that on the other cord resembled a pea in shape and size. There was no further growth of the tumours. Ten weeks after his first visit the patient was admitted into the hospital in consequence of a spasmodic laryngeal attack in the out-patient room, from which, however, he soon recovered. For the four months he remained in the hospital he had slight spasmodic attacks from time to time depending upon the varying degree of swelling of the aryepiglottic folds. The tumours remained unaltered, and there was no change in the pulmonary condition. The aortic second sound was noticed to be much accentuated, and occasionally a systolic murmur was heard under the left clavicle, which was thought to be due to aortic dilatation or aneurism. The patient was discharged after his condition had become stationary, the physical state of his chest and larynx being unaltered. A month later he appeared in the out-patient room with signs of excavation of the left lung, and with much swelling of the aryepiglottic folds, but without any change in the appearance of the tumours. He was readmitted in a very weak state, and gradually became worse. The laryngeal obstruction increased so much that tracheotomy had to be performed during a spasmodic attack, in order to save his life, but he sank two days later. The post-mortem examination revealed pulmonary phthisis of a fibroid type in the left lung, tubercular ulceration of the posterior wall of the larynx and of the trachea, with symmetrical pea-sized tumours situated over both processus vocales; atheroma and dilatation of the aorta; granular contracted kidneys; fatty liver; tubercular ulceration of the colon. A microscopical examination of the tumours showed that they were an outgrowth from the lateral aspect of the inter-arytenoid fold, and consisted of collections of subepithelial miliary tubercles, and of a cellular infiltration of the mucosa and sub-mucosa. Tubercle bacilli were found in abundance in the miliary tubercles and in the cell infiltration. In the *Wiener Med. Presse*, April, 1883, Schnitzler records a case in which he diagnosed multiple tuberculous tumours of the larynx. The tumours were removed with the guillotine, and proved to consist of aggregations of miliary tubercles. Schnitzler believes that his is the first case in which such tumours have been recognised during life.

Dr. WHIPHAM quoted a case in his own practice of a similar kind. It was that of a man, a free drinker, and the diagnosis was doubtful between syphilis and tubercle, but the only physical sign of phthisis perceivable at first was emphysema of the apices and anterior borders of both

lungs. The arytenoid cartilage of the left side was enlarged, and two months later a similar change affected that of the right side also. Thenceforward marked evidences of lung mischief were apparent, crepitations and breaking down following in quick succession, and were succeeded by death of the patient.

Dr. HALL had seen several instances of tuberculous larynx ensuing in syphilitic subjects of phthisis, and they had all terminated fatally. Dr. Kidd's case was a rare example, on account of the long period, nine months, during which no ulceration of the larynx had set in.

The PRESIDENT suggested that the delay might have arisen from the occurrence of fibroid changes in this case.

Dr. KIDD explained that his patient had exhibited no such changes, and until this experience he had never even heard of cases in which tuberculous tumours of the larynx had been observed. Very recently, however, he had seen two similar cases. In one the tumour, as large as a small bean, was situated on the ary-epiglottidean fold: ulceration was rapidly fatal. The other case occurred on the post-mortem table.

THREE CASES OF CANCER OF THE RECTUM.

Mr. CRIPPS read the notes of three cases of cancer of the rectum in which he had excised the lower part of the bowel, the operations having been performed respectively seventeen months, eighteen months, and four years ago. In the first case, that of a man, *æt.* 68, the symptoms had existed for two years. The disease consisted of a hard, irregular mass on the posterior and right wall of the rectum, about two-thirds of the circumference of the bowel being involved, the disease not extending more than two and three-quarters of an inch from the anus. The lower three inches of the bowel were removed, with the exception of about one-fourth of its circumference on the anterior wall. The patient was much troubled during his convalescence from symptoms arising from enlarged prostate, but was discharged in a satisfactory condition so far as the bowel was concerned. At the end of a twelvemonth his medical attendant wrote that he was alive and comparatively comfortable, no return of the disease could be detected, but he was unable completely to retain his fæces. Mr. Cripps had examined this patient since sending in the paper, and found that he was suffering considerably from prostatic troubles. There was some hardness in this neighbourhood, but no certain symptoms of recurrence. The second case was that of a lady, *æt.* 60. The disease extended all round the bowel on the anterior wall, nearly as high as four inches. Mr. Cripps did not regard the case, from its extent, as a very favourable one for operation, but at the wish of the patient undertook its removal. The bowel had to be dissected for two inches from the peritoneum. The patient made a very satisfactory recovery; she suffered much from contraction, but there was no recurrence for more than a year. The disease then recommenced. The last case was that of a lady, *æt.* 40, who was recommended to the author by Dr. Matthews Duncan. The disease consisted of a hard ulcerated mass, involving one-half the circumference of the bowel to a height of two inches, and filling the ischio-rectal fossa. The disease was removed in July, 1880, and proved, under the microscope, to be a typical example of adenoid cancer. The patient has been frequently examined since. She has completely regained her old strength and health, has no pain or discomfort whatever, and remains, after nearly four years, perfectly free from any symptom of recurrence. Mr. Cripps remarked that he was much indebted to Mr. Butlin for his assistance in the operations performed.

Mr. MORRANT BAKER said he had operated on three cases of cancer of the rectum. One died of peritonitis, the other two recovered. He endorsed the opinion that great benefit resulted from the operation. In one of his cases, that of a woman, a large amount of tissue had to be removed, including the recto-vaginal pouch; but even in this only a slight amount of trouble was subsequently experienced. Later on the disease returned and death ensued. The third case, also a woman, did very well, and when seen two years after the operation, enjoyed good health, and went about in comfort.

Mr. WALSHAM had also experience, personally, of three cases, all seemingly favourable for operation, the tumour being situated posteriorly, and being all of it removed in two. One died three months after operation, but no post-mortem was obtained. Another died three days after operation, of septic infection. In the third case it was found impracticable to extirpate the diseased bowel entire, but still

a good recovery was made, and in four weeks the man was able to resume work. Now, however, the cancer was returning. Mr. Walsham urged the importance of forming a diagnosis when the patient was under an anæsthetic, and also that scissors should be used in preference to the *écraseur*, bleeding vessels being tied as they were divided. It might, he considered, be desirable to remove even a part of the cancer where all could not be reached.

Mr. DENT observed that contraction of the gut after operation, and escape of fecal matter, were the main points to be considered. The trouble caused by the latter condition might be mitigated by deferring to dilate for threatened stricture till later than was usually done. It was a pity that an operation otherwise so promising should be followed by such accidents.

Mr. BARKER narrated the history of a case in which he had removed a cancerous rectum from a man, *æt.* 58. Dilatation was not attempted. When seen three months later, he said his only trouble had been looseness of the bowels whenever he indulged in beer. Then it was impossible to force the finger inwards more than $1\frac{1}{2}$ inches, but notwithstanding the motions readily passed. All the circumference of the gut had not been removed in this case. The disease recurred after 14 months. A second operation was done; death occurred from cellulitis. In another, the only other case Mr. Barker had operated on, death followed from cellulitis in a few days.

Mr. GODLEE had operated on one case only. The patient was a man about 70. The cautery was employed, and this instrument was approved by Mr. Godlee on account of the control over hæmorrhage it provided. Stricture and incontinence occurred afterwards, and dilatation was resorted to with resulting relief, and the patient was now at work again. A plastic operation, or even colotomy, might, Mr. Godlee thought, be desirable in extreme instances of stricture; and in illustration of the chronicity of the disease in question he instanced the case of a woman operated on by Simon, of Heidelberg. This woman returned periodically to have recurring cancer scraped away, and this took place a considerable number of times.

Sir ANDREW CLARK said that his own experience taught him that the duration of life of these cases was longer than books commonly assigned to them. He once diagnosed cancer in a lady who lived for six years after; and he had during the last two or three years seen more than twelve cases in conjunction with Sir James Paget. In all, the duration of life exceeded that given to such patients in books.

Mr. CRIPPS had not known any instance of a patient suffering from cancer of the rectum in which, in the absence of any operation, life had been prolonged beyond eighteen months. Indeed, he was surprised to find how rapidly a fatal termination occurred. Operation afforded favourable chances. In one case he removed a cancer eight years ago. It recurred and was again excised. Six months after it was once more cut out, in 1877, since when there has been no return of the disease. He agreed in preferring the scissors, which in his two latest cases he had employed. For high operations the *écraseur* was advisable. Successful results might be expected in cases where the finger could pass beyond the growth, and in which the bowel was freely movable. Incontinence might be remedied by use of pads, &c. Contraction of the bowel was a much more dangerous complication, and in view of the possible obstruction it might cause, he would advocate early employment of bougies to dilate. In extreme cases he would resort to colotomy.

Dr. ANGEL MONEY communicated a paper on a

REMARKABLE CASE OF TUBERCULAR MENINGITIS.

The patient was a female infant, *æt.* 9 months, when first seen on December 7th, 1883. It appeared that the child had enjoyed good health till about five months previously, when it had the measles, but apparently recovered completely in a short space of time. On November 27th the child had a fit, shortly after which the left arm and leg were found to be completely paralysed. The intelligence was, so far as could be judged, unaffected. The corporeal state was decidedly one of great fatness. The condition of hemiplegia seemed to be slowly passing away, until December 27, when a series of fits set in, unconsciousness supervened, and the patient died on January 2nd. On January 1st there was hurried and somewhat Cheyne-Stokes breathing; the pulse was regular, 96, but no fever. The temperature on the morning before death, however, was taken in the rectum and found to be 107°.

At the autopsy the brain was soft and pale, with considerable excess of pale clear fluid in the lateral and fourth ventricles, but without glueing of the cerebellum to the posterior boundaries of the last-named ventricle. There were signs of not recent meningitis, chiefly at the base, and a large branch of the right middle cerebral was found to be thrombosed. The other organs showed signs of tuberculosis. A minute vegetation existed on the smaller flap of the mitral valve. In his remarks on the case, Dr. Angel Money pointed out the difficulties of diagnosis. He said that in children the symptoms and signs of disease were singularly wanting, especially when we had to do with the brain. A mass of disorganisation in a child would produce much fewer signs than an equal amount of damage in an adult, and this was still more the case, the younger the child.

Dr. O'CONNOR inquired as to the state of dentition in Dr. Money's case.

Dr. GLOVER described the case of a man who, in January last, was attacked by a temporary hemiplegia, which occasionally recurred during the next few days. He had been exposed to cold, on an empty stomach. After a time he recovered, and the only symptom remaining was slight vertigo, in addition to permanent dilatation of the pupils.

Dr. TONGE SMITH narrated the case of an infant affected with temporary paralysis; pyrexia supervened, and death occurred from tubercular meningitis.

A MEMBER instanced a case in which a business man was attacked one day by evanescent paralysis, and died suddenly the day following.

Dr. MONEY said his patient had cut two lower incisors. The paralysed limb was cold.

BRADFORD MEDICO-CHIRURGICAL SOCIETY.

MARCH MEETING.

W. H. ELLIS, M.R.C.S., President, in the Chair.

Dr. WHALLEY introduced, as follows, a general discussion on

CRANIOTOMY.

The important subject which we have met to discuss this evening, has for its aim the accomplishment of delivery by the sacrifice of the child. Perforation of the foetal head was one of the very early operations of midwifery, it was practised by Hippocrates, and though but little change has taken place in the mode of performing the operation since his time, an almost infinite variety of instruments have been invented for the purpose. Those most commonly employed are the perforator and the forceps, which are used for extracting the child. Dr. Churchill finds that with regard to the statistics of the operation, taking the average practice of this country in 173, 625 cases of labour, perforation was resorted to 563 times, or about 1 in 308 $\frac{1}{2}$. In France and Italy the frequency is about 1 in 563 $\frac{1}{2}$, and in Germany 1 in 1,675. The conjoint tables give a total of 859,178 cases of labour, with 1,018 cases of craniotomy, or 1 in 844. From the only table where the result of the mother is stated, it appears that of 800 cases, 141 ended fatally, or about 1 in 5 $\frac{1}{2}$; but in private practice the result is very different, for of 161 cases only 7 died, or 1 in 23. It has been my misfortune during the last 23 years, to have to resort to the perforator 15 times in 2,920 cases of midwifery, in 13 instances it was applied to the head, in 1 to the chest, and in 1 to the neck, in order to decapitate. Of these cases 11 mothers recovered and 4 died; of the latter, one, a primipara, who resided in a very insalubrious locality died at the expiration of a week from septicæmia. I believe if the operation had been resorted to earlier, a better result might have been obtained. The second case was one of pelvic distortion; she died from accidental hæmorrhage on the second day. The third case was also one of pelvic distortion; she died from exhaustion, the result of prolonged instrumental labour. The fourth, *æt.* 39, a primipara, was extremely feeble and was delivered of a putrid foetus, and died on the fourth day, from septicæmia. At one time it was the rule to wait until the child was dead, but this rule is now happily obsolete, by this practice the danger to the mother was increased while nothing is saved to the child. Authorities differ widely in their opinions as to the conditions which should justify a resort to the proceeding, some

affirm that through a diameter of an inch a mutilated child can be extracted; while others think unless there be a space of fully two inches, the danger to the mother is so great that it would be better to have recourse to the Cæsarean section. The majority seem in favour of the latter view, and, judging the results obtained, this rule seems by far the safer. For my own part, in a case where the diameter did not exceed two inches, I should urge the Cæsarean alternative, believing, as I do, that in cases of such distortion the danger to the mother nearly equals that of the Cæsarean, while the life of the child is necessarily lost in the one, most probably saved in the other. In order to refresh the memory, I may just state that the average measurements of the dried female pelvis are the following: The antero-posterior diameter is $4\frac{1}{2}$ inches; the transverse, $5\frac{1}{2}$; and the oblique, $4\frac{1}{2}$. A conjugate diameter of pelvis, of $3\frac{1}{2}$ inches, will not admit the passage of a living child of average sized head at the full term. The cases requiring the perforator are:—1. "Where the pelvis or soft parts are deformed, by tumours or otherwise, to such an extent that either the conjugate diameter at the brim, or the transverse at the outlet, measures less than 3, but not less than 2, inches. The normal dimensions of the pelvis may be thus reduced, either by simple pelvic deformity, the result of rickets or of mollities ossium, or by tumours connected either with the pelvis—bony, or enchondromatous, or with the pelvic organs, such as ovarian or fibroid tumours of the uterus. Cancer of the uterus is also thought by some to justify craniotomy, but, considering that disease must before long prove fatal to the mother, I could not, under these circumstances, sanction the sacrifice of the child—at least not if the cancerous disease had advanced far and invaded the whole cervix—the Cæsarean section, in such a case, seems to me the obvious method of treatment. I have read of two cases in which the child was pulled piece-meal through a cancerous uterus and vagina with so much injury to the mothers that they died, the one in a few hours, the other in a few days. Such practice is, in my judgment, wholly unjustifiable, and is a scandal to our art. 2. Cases where, without any abnormality of the pelvis, there is such a disproportion between it and the child, that the extraction, by the natural passages, of a living child is impossible. Hydrocephalus is a case in point. 3. Certain cases of malpresentation, as for instance of the arm, together with the head, where the former projects into and even beyond the vagina, and cannot be returned, both head and arm being firmly wedged in the pelvis, the liquor amnii having escaped, and the uterus firmly contracted on the child. In like manner some cases of face-presentation may require to be thus treated. 4. Where the labour is very tedious, and the child dead. Here there is no object in waiting, for the child is beyond recall, and the mother is certain to be injured more or less by the continuance of the uterine action, when no progress is made. 5. Cases requiring speedy delivery, the process is inapplicable, such as certain cases of convulsions, rupture of the uterus, some forms of dangerous hæmorrhage, exhaustion," &c. I think no fixed rule can be given as to the period when the operation should be performed. As soon, however, as it is clear that a live child cannot come by the natural way by any known process of obstetrics, we ought to decide upon the operation. It is probable that from waiting too long that the maternal mortality in this country is so high after craniotomy. I will not weary you with the details of all the cases of craniotomy I have met with, but will give, as briefly as possible, the particulars of a few, which I may call "typical cases." *Case I.*—Mrs. T. B., arm presentation, pelvis contracted in antero-posterior diameter, it was the patient's seventh confinement, has had four cross births, and only one living child, version was performed in present case, child dead, perforated the skull behind the ear. Mother made a good recovery. *Case II.*—Mrs. W., diminution of the pelvis in the conjugate diameter, it was impossible to deliver with forceps, patient had been in labour a whole day, craniotomy performed. Mother soon recovered. *Case III.*—Mrs. M., called at 4 a.m., patient had a sudden gush of hæmorrhage—7½ months advanced—ruptured the membranes, hæmorrhage ceased. Called again at 3 a.m. following day, found placenta presenting, patient much exhausted from loss of blood, pains feeble, hæmorrhage still going on, perforated skull, applied forceps and delivered. The mother made a rapid recovery. *Case IV.*—Mrs. D., a multipara, was very anxious to have a living child, has always experienced

difficult, lingering labours, all her children, with one exception, have been still-born, or have died immediately after delivery. On examination the patient was found to possess that rare deformity which has been termed by M. Nægele, "the obliquely distorted pelvis." I applied the forceps, but found the space insufficient to admit of extraction, with safety to the mother. I then determined to turn, this was effected with great difficulty; after bringing down the body and shoulders, profuse hæmorrhage ensued, and finding it impossible to bring the head through the brim I perforated behind the ear. The patient lost about a quart of blood, from the effects of which she died the following day. *Case V.*—Mrs. C., a multipara, with diminution of the pelvis in the conjugate diameter, complicated with extreme obesity of the patient, rather than allow premature labour to be induced artificially, had exposed herself to all the dangers of craniotomy three times. She made a good recovery from this, the fourth operation. *Case VI.*—This case, a primipara, resembled in most respects the one just described, except that the tubera ischiorum were more closely approximated; she was, with considerable difficulty, delivered by craniotomy, and died on the third day. This patient obstinately refused to have labour brought on at the seventh month. *Case VII.*, and the last which I shall cite. —*Et. 25*, like many of the other cases, presented many of the characters frequently associated with distortion of the pelvis, the result of rickets in childhood, being three years old before she could walk. On examination, the promontory of the sacrum was found projecting forwards, the symphysis pubis was flattened, and pushed towards the former, the lateral diameter being increased, the bulk of the head of the fœtus remained above the brim. The forceps was applied, but extraction could not be effected with impunity. The case was terminated by craniotomy. The mother made a rapid recovery. With respect to the dangers of the operation, as regards the child we may almost say that there is no danger, for the simple reason that its destruction is the essence of the operation. The danger, therefore, has reference only to the mother, and perhaps the greatest of all, because so common, is the injury which results from too long delay, in the shape of inflammation, sloughing, &c., of the maternal structures giving rise to vesico-vaginal fistula, to cicatrices about the cervix uteri, and vagina, to metro-peritonitis, cellulitis, and possibly even to shock, exhaustion, and death. Injuries to the uterus and vagina during the operation are avoidable with ordinary care and judgment, and most of them can only occur as the result of either gross ignorance, or of equally culpable neglect. But in this, as in so many other cases, ignorance is far more responsible for injury than neglect. Before concluding, I must say a word or two on the cases requiring the use of the cephalotribe. They are generally those which render craniotomy necessary, and further, it is applicable to cases where the perforator and craniotomy forceps would most likely fail, or at least, in which their use would be attended with great difficulty and danger. Some authorities have recommended it in cases with a conjugate diameter of only $1\frac{1}{2}$ inches, or even $1\frac{1}{4}$ inches, but this appears to me to be most unsound practice, for I believe the risk to be fully equal to that of the Cæsarean section, which would at least give the child a chance of life. On the Continent, where the cephalotribe was first used, the general opinion is in favour of 2 inches, and probably that is the safest point to fix upon; though, in this country, $1\frac{1}{2}$ inches in the conjugate, with a transverse diameter of $3\frac{1}{2}$ inches, are the dimensions which are thought fairly to justify the performance of cephalotripsy. Dr. Barnes is convinced "that cephalotripsy is quite practicable with a pelvis measuring $1\frac{1}{2}$ inches in the conjugate diameter." It may be so in his hand, but I very much question if it be as a general rule, and it must be remembered that his opposition to the Cæsarean section is very determined. Nowhere, perhaps, is this more visible than when he adds, in the same sentence, that the risk of cephalotripsy, with a pelvis which measures in the conjugate only $1\frac{1}{4}$ inches, is inconsiderable compared with that attending the Cæsarean section. I have found the cephalotribe a most valuable form of craniotomy forceps, it diminishes very greatly the risks to which the mother is exposed in all cases of severe pelvic distortion during the process of extraction. And now, gentlemen, without trespassing further upon your time, I will ask you to discuss this most important subject with that candour, and in the light of that scientific experience,

which has ever characterised the meetings of this admirable society since its commencement.

The PRESIDENT said that Dr. Whalley's experience justified his appointment to lead off this discussion. He had enlarged the subject to all those operations involving the destruction of the child before birth. The use of the long forceps had latterly diminished the necessity for craniotomy. He had been surprised to observe, however, that craniotomy had been performed in Dublin four or five times oftener than the use of the long forceps. He thought it morally wrong to perform craniotomy four or five times on the same subject, seeing that premature labour might be induced instead. Cæsarean section was preferable to craniotomy, and he thought would yet become more general.

The SECRETARY then read a letter from Dr. Hime, regretting his inability to be present at the meeting to say a word in favour of conservative surgery, so far as fetal life was concerned. He (Dr. Hime) thought there was a growing tendency to undervalue fetal life in cases where there were risks to both mother and child.

Mr. R. H. MEADE said the completeness of Dr. Whalley's paper had narrowed the scope for discussion. An important point for young practitioners was to determine when to operate, and how long to wait before doing so. He advised the trial of the long forceps in the first instance, and failing them, turning, because to deliver the head it was easier to perforate behind the ear. There was great danger to the mother in delaying the operation too long. He had been called in to a case where the body had been pulled away, leaving the head still in utero, the delivery of which head was only effected with great difficulty. The cephalotribe was useful in such cases if well-handled, but, indeed, the use of all instruments was not unattended with danger. Notwithstanding the mortality in craniotomy, he should yet hesitate to run the risk of sacrificing the mother by resorting to Cæsarean section.

Dr. RABAGLIATI, alluding to the Cæsarean section *versus* craniotomy, thought that the mortality of the former was due to the method of its performance. Hey and Jessop, of Leeds, with others alleged that the fatality of the operation was lessened by leaving the placenta to be delivered *per vias naturales* after extraction of the child, why, he could not explain. He thought that if the operation were performed antiseptically it would become safer, though antiseptics would not prevent sloughing of dead parts. In consequence of fault being found with a medical man, who performed craniotomy because he had not examined the woman at the seventh month and induced premature labour, he inquired whether a medical man was bound to examine every woman during her pregnancy. This he thought an important question; ladies did not like an examination to be insisted upon, yet in this case, and others he could mention, the medical attendant had suffered in reputation from not having made a previous examination.

Dr. TIBBITS had had little experience of craniotomy. He thought that where craniotomy had once been performed impregnation should be avoided, or premature labour afterwards be induced. It was of course impossible for medical men to prevent the former, and insistence of abstinence on moral grounds might lead to immorality, an undesirable result. It was the opinion of the Dublin physicians that the increased use of instruments was the cause of the increased mortality in mothers. In 500 cases of midwifery he had had he only performed craniotomy twice. In one of these cases there was such inertia that he had to apply the forceps, the patient dying suddenly afterwards; in this case he blamed his own delay.

Dr. JOHNSON denied Dr. Tibbits's inference that the use of instruments increased mortality; he thought the cause of death due to delay in their use; he never hesitated to use forceps when he deemed it necessary, and he had never had a death in consequence. They should always be used slowly and with the pains. In many cases, the state of the parts necessitated either craniotomy or the Cæsarean section. He was pleased to notice the records of several recent cases in which both the mother and child had been saved by Cæsarean section; in one or two of these the uterus also had been removed, thus avoiding all the risks of future pregnancies. Possibly, if after the head had been emptied, and the child left still in utero and the pains were going on strongly, the natural powers might be sufficient to deliver the child.

Mr. DENBY remarked that, failing the natural powers, turning and delivery might then be more easily effected.

Dr. GOYDER said the discussion had somewhat wandered from its direct subject. Careful examination and experience would very soon lead the practitioner to decide upon those cases which required craniotomy; the main points being the contraction of the pelvic brim, the condition of the child, and the powers of the mother. He pointed out the importance of completely emptying the head and destroying the medulla oblongata, as he had known children to breath and cry upon being delivered after craniotomy. He said that the operation for delivery was much facilitated by leaving the child in utero for twenty-four hours after perforation, the parts meanwhile becoming limp and flexible. This plan he had learnt from Drs. Beach and Brown, two old and experienced Bradford practitioners. With regard to deciding whether, before operation, the child was dead or not, there were the absence of the sounds of the fetal heart, the softness and pliability of the cranial bones, and the further fact that the uterus was not firm and steady with a dead child, but fell from side to side with the motions of the mother. He did not believe a medical man ought either to be compelled or to insist on making an examination during pregnancy, unless circumstances demanded it.

Dr. WHALLEY, in replying, said, the President's remarks relative to the operation of craniotomy being less practised in Roman Catholic than in Protestant countries was undoubtedly owing to the fact that, in the former, infant life is held more sacred than in the latter; like Mr. Ellis, he invariably uses the long forceps. In all suitable cases of recognised pelvic deformity he has advocated and practised induction of premature labour, having in one patient performed the operation five times successfully at the seventh month. His experience accorded with that of Mr. Meade's, respecting the advantages of version in certain cases of pelvic deformity, but, like him, he had not infrequently to resort to craniotomy, in order to terminate the case. Mr. Meade's experience confirms the general opinion that the high maternal mortality after craniotomy is due to the operation having been too long delayed. Dr. Rabagliati's remarks with reference to the advantages of the Cæsarean section over craniotomy and cephalotripsy in certain cases of extreme pelvic deformity accorded with his own views, and recent experience favoured the opinion that it is better not to remove the placenta at the time of the operation. Dr. Whalley thought the other questions which had been raised during the discussion by Drs. Rabagliati and Johnson, viz., the signs of a dead foetus, the social and moral conduct of a patient possessing a deformed pelvis, and the moral obligation of the medical practitioner had been satisfactorily dealt with by Drs. Goyder and Tibbits. He testified to the truth of Dr. Goyder's observation that the removal of the foetus was facilitated by leaving it in utero for twenty-four hours after perforation, but remarked that this could not be done in some cases, where delivery itself was urgent and necessary.

Mr. MEADE said that a medical man was certainly not called upon to suggest examination during pregnancy, unless something very unusual justified his doing so; young medical men should be particularly careful in this matter. From the figure and general appearance of a woman one might hint at the necessity for premature labour being induced. Mr. Meade alluded to certain insurance companies requiring special examination in cases of suspected pelvic deformity; the propriety of acceding to this request he thought matter for discussion.

PREPARATIONS are in progress for celebrating the 500th anniversary of the foundation of the University of Heidelberg. The Baden Chamber has shown its sense of the importance it attaches to the occasion by voting the sum of 160,000 marks towards defraying the expenses connected therewith.

DR. JOHN A. VOELCKER, B.Sc., F.C.S., will deliver a lecture on "Milk," at the Parkes Museum, Margaret Street, W., to-morrow (Thursday), at 5 p.m. The chair will be taken by the Rt. Hon. Sir Thomas Dyke Ackland, Bart., M.P.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, APRIL 23, 1884.

THE FUTURE OF THE ROYAL COLLEGE OF SURGEONS OF ENGLAND.—III.

THE Presidency of the College is not only the highest official distinction to which British surgeons can aspire, but it is also an office which should confer upon the holder a power of influencing movements designed in the interests of general professional advancement and improvement. Under existing arrangements, however, it is impossible to conceive that anything of this kind is associated with it, and the reason is not far to seek. Elected for no longer than a single year, and proceeding to office under conditions which eliminate every element of popular choice, the President must necessarily feel how merely ornamental a figure he is designed to be, and will have naturally crushed out of him every impulse towards reform that might possibly have stirred him at an earlier stage of his career. By the time he reaches the lofty summit of his ambition as far as College matters are concerned, he has served an apprenticeship as councillor, which, as events have shown, most efficiently fit him to discharge such ceremonials as are part and parcel of the premier office; but above and beyond this, in the way especially of influencing the outer world to better appreciation of surgeons as a section of the body politic, his weight is, except in the rarest instances, *nil*. Occasionally it does happen that there chances to be President a man of commanding intellectual presence—one whose word and work is recognised as entitling him to wider acknowledgment and respect than can ever be hoped for by the great

majority of surgeons, howsoever faithfully and diligently they have prosecuted their lives of labour. No one, however, can dispute that a great corporation like the College ought at all times to be ruled by one to whom a universal and ungrudging title of scientific pre-eminence is accorded. Such men, it is true, cannot be found each year to undertake the duties of the office in question, and in this annual election of President is to be discerned one of the worst weaknesses of the present rules governing the internal affairs of the College. Around it, also, are encrusted other and only less mischievous regulations connected with the mode of election, points which have already been sufficiently dwelt upon in preceding articles.

In the first place, then, the Presidential chair must be held for a longer period than is now the case, for until this is done it will be impossible for its holder to exert more than a nominal influence over the profession. As it is, not one out of a hundred members knows who is its occupant; nor is this surprising when we reflect that the question of election is entirely an uninteresting one save to the twenty-four gentlemen who actually perform the ceremony of choosing, and who all either have been or hope to be, in turn, themselves in a similar position. Tenure of office, to be anything more than an empty compliment, must continue for a term of years, not, certainly, less than three, and probably five or seven would be found advantageous to the College in every way. Again, there is abundant reason for radical amendment of the conditions which constitute eligibility for the chair. Among a number of Fellows and Members so great as that attached to the College of Surgeons there will always be some who have achieved the highest reputation, but who at the same time are precluded by various circumstances from participating in the management of the College as it is constituted at present. Their exclusion is a manifest disadvantage to the general welfare of the College as a whole; and as long as they continue to be excluded a serious evil will be perpetuated, against which both fellows and members are justly entitled to protest.

Without exposing ourselves to the risk of censure, we may be permitted to infer that a good many names are to be found in the list of Presidents of the Royal College of Surgeons which would never have been placed there had the area of choice not been circumscribed as it has been in the past. On the other hand, there are many, also, which but for the hard and fast rule respecting annual tenancy of the chair, would be found year after year, for many years; and had this but been the case a very different aspect would have been borne by the College than that it now presents. The principle here insisted on has, moreover, been frequently recognised even by the College executive, for in a majority of instances the same gentleman has been called to the Presidency twice, and in one case re-election was twice conferred on the same retiring President. Since 1862, however, no holder of the office has occupied the chair for two years; and it must be remembered that in those cases where, previously, re-elections took place, an interval of several years separated the various tenures of office. At the Royal

College of Physicians of London, observance of the rule that Presidents shall continue in office for several years in succession confers very manifest advantages on the corporation. The President thereby becomes associated with, and gives a personality to, the College, the importance of which cannot be over-estimated; while the *prestige* it confers upon the President himself is of a kind that must often excite a vain regret in his brother head of the Surgical College.

The resolution forwarded to the Council demands that henceforth the President shall be elected at a general meeting, and by the Fellows there assembled. For this to be carried it will be necessitated that the Council shall voluntarily resign the privileges it now enjoys in this respect, and merge into the unsympathetic hands of twelve hundred electors the choice that its twenty-four members have so long exercised. But, though the resolution does not explicitly say so, it certainly implies that, given the power to choose, such choice will not be confined, as that of the Council is, to members of that body, but will be free to fix on any Fellow of the College deemed most capable and suitable to fill the chair with advantage to the common weal. If the powers to be committed to a general meeting are limited as those of the existing electors, but little benefit will be found to accrue; and it may therefore be taken for granted that along with the demand already formulated will be granted also the extension of the field of candidates referred to above.

MEDICAL COUNCIL OPINIONS ON THE DIRECT REPRESENTATIVE.

WE have often thought that there must be great self-satisfaction to the curate who is wont to dogmatise from the pulpit in the feeling that the rostrum is all his own, and that he need fear no replies or criticism from any of his audience who may think that he has been talking nonsense or making rash statements. It must indeed be a great aid to oratorical effect when a speaker is relieved from any apprehension as to his facts and arguments and able to devote his mind to the neatly turning of his phrases and to the scourging of his antagonists. Mr. MacNamara had his opportunity when he made his famous speech of the 1st of April (ominous date) against the "direct representative" in the complacent ears of the Medical Council, before whom he was safe from either contradiction or replication. But he should have taken the precaution to "square" the reporters, so that his very peculiar pronouncements should not reach the eyes of any one able or willing to meet him with refutation and with the ridicule which his oration deserved. Here is an extract from Mr. MacNamara's speech as reported by a contemporary:—

"The Medical Council had been the subject of constant abuse as a 'fainéant' body, and as not having exercised its powers to report bodies to the Privy Council. The result of a provincial agitation in Ireland was that when the matter was brought before the Irish College of Surgeons, only seven Fellows voted for direct representation. Some of the most distinguished members of the Council had expressed themselves against direct representation; and when he remembered the important duties of the

Council in regard to education, he could not conceive that a country practitioner, say from Essex, would be a better representative than any of the distinguished members who now composed that body. The agitation was but a journalistic one, got up by parties who sought by direct representation to get access to the Council Chamber."

Without further preface we may characterise the statement that direct representation was brought before the Fellows of the Irish College of Surgeons and supported by only seven votes as absolutely inaccurate, and without any foundation in fact. The question was never submitted to the Fellows, and Mr. MacNamara ought to know enough of the feeling of the College constituency to know that their voice is almost without exception in favour of reconstitution of the Medical Council, and that the entire provincial element and most of the metropolitan Fellows, are favourable to the introduction of a direct representative into that body.

The statement that the movement for this method of reform of the Medical Council is "a journalistic one got up by parties who sought by direct representation to get access to the Council chamber" is, no doubt, meant as an insult to those who have taken a leading part in the agitation, but it is equally an insult to the profession at large who have lent their countenance to that agitation, if it be not the result of indefensible ignorance of the facts.

If Mr. MacNamara were speaking where he might be answered, would he have ventured to say that a demand is merely journalistic and personal which has been persisted in from 1867 until to-day, which has been affirmed each year in the public meetings of every professional organisation, which had its inception in a memorial from 5,200 independent practitioners, which was reasserted on a plebiscite by 5,075 votes against 121, who held Mr. MacNamara's opinion, and which was assented to with more or less force in their evidence before the Royal Commission by the representatives of every licensing body in Ireland, and many of them elsewhere?

Aye! and assented to by Mr. MacNamara himself. When he permits himself to attribute personal motives and political dishonesty to those who have advocated direct representation, does he forget that on the 3rd of July, 1878, in his place in the Medical Council, he himself voted with Sir Dominic Corrigan and Dr. Haughton in favour of the opening up of the question of the reconstitution of the Medical Council, that he voted against a motion which was intended as a counterblast to direct representation, that he received—with his two distinguished co-voters—a resolution of thanks from the Irish Medical Association for his support of direct representation, and that, when in the following year he deserted Sir Dominic Corrigan and Dr. Haughton, and voted against reconstitution, his name was removed from the executive of that Association?

If these facts had been stated to the Medical Council perhaps Mr. MacNamara might not have been so well pleased with his rhetorical effort. Next time he thinks fit to publicly attribute self-aggrandisement as the motive of his political opponents, it will save eventual trouble if he will look up the facts before making the accusation.

Notes on Current Topics.

Typhoid Bacillus.

AN attempt to isolate the bacillus of enteric fever will probably be made under the stimulus given by the munificent offer of a Fellow of the Linnean Society of New South Wales to give a prize of £100 for the best essay on "The Life-History of the Bacillus of Typhoid Fever." Compositions must be written in English, and delivered at the Society's house by December 31st next. The objects to be kept in view by competitors are thus explained by the donor of the prize:—1. The specific characters of the organism whereby they are distinguishable from other forms of bacteria. 2. The changes through which the bacillus passes in the human body. 3. Its mode of development and reproduction in the human body. 4. Its changes, if any, after removal from the body, or under any other conditions of its existence. 5. The fluids or other substances best adapted for the growth of the organism. 6. The power of the organism to exist in pure or distilled water. 7. Its limits of endurance of heat, cold, desiccation, and moisture. It is explained further that, "as far as these points are concerned, the author should confine himself entirely to facts which come under his own observation, which should be fully detailed with a full explanation of the method of investigation. But, in dealing with the results obtained by these investigations, and the consideration of the means whereby a knowledge of the life-history of this most dangerous organism may help towards its eradication, the theories and observations of others may be referred to; but in every such case the authority must be correctly cited. The chief points to be ascertained on this branch of the subject are:—1. How and under what conditions does the organism gain access to the human body? 2. How can its growth be impeded, or its vitality destroyed in the human body without serious injury to the individual affected? 3. How can it be eradicated or rendered innocuous in wells, water-holes, drains, &c.?"

An Ominous Fact.

PROBABLY no greater misfortune ever befell this country, apart from national catastrophes, than that occasioned by the paralysis of anti-syphilitic sanitation by the memorable vote on Mr. Stansfeld's fatal motion last year. By-and-by the evil will attain such proportions that an irresistible demand for scientific legislation will be made; and as the time approaches nearer and nearer, we daily perceive accumulating evidence that its advent is rapidly hastening. Such significant proceedings as those which occurred on April 6 at Colchester must convince even the most purblind defender of free trade in syphilis that the country will not long consent to yield assent to their doctrines. At the recent Quarter Sessions at Colchester the Grand Jury made a presentment calling attention to the increased immorality in the town since the modification of the Contagious Diseases Acts came into force; and the Recorder, when acknowledging its receipt, made the startling declaration that since the suspension of compulsory examination the

number of cases in the military hospital had increased three hundred per cent. After further remarks on the irreparable injury done by the cessation of examinations, the Recorder continued: "I can only say that I for one, having heard and having made it my business to inquire into the operation of the mode of enforcement, most thoroughly and heartily agree with you. I will take care your presentment shall be forwarded to the proper quarter, where I hope it will receive the attention it deserves as coming from those who, having lived in a town where these Acts have been in force, are better qualified to judge of their operation than the number of people who judge this matter, however sincere they may be, more from theory than from actual experience."

In the face of such testimony as this, and testimony, too, which finds an echo in every quarter which has been affected by the withdrawal of compulsion, it is foolish to attempt a refutation of the nonsensical fables quoted by those who, in this, array themselves against order and decency by clamouring for unconditional repeal. Before long, it is to be hoped, the whole question will receive the attention it deserves, and as a result that a much-needed return to an even stricter régime than that temporarily suspended will be announced.

The City of London Coronership.

By the sudden death of Mr. W. J. Payne, which took place last week, the office of Coroner for the City of London, Southwark, and the Duchy of Lancaster, is rendered vacant. It is sincerely to be hoped that the contest that will arise in this connection may result in the election of a medical candidate, for in the City more than in any other place a knowledge of medical matters is of the utmost importance to a coroner. Dr. Wynn Westcott, who has for some time assisted Dr. Danford Thomas as deputy coroner for Central Middlesex, is, we are glad to learn, a candidate for the vacancy; and we can imagine no one better calculated to perform the duties of it with complete satisfaction.

A Puzzling Tumour.

MR. BELLAMY exhibited a case at the Clinical Society on Friday evening the nature of which could not be satisfactorily determined. The patient is a youth, about 16, who is unable to afford any sufficient explanation for the presence of the tumour. This consists of a diffuse elevated swelling, extending over the lower half of the sterno-mastoid muscle, from the middle line of the neck in front and outwards as far as a line drawn from the ear. The skin over it is of a bluish colour, and contains many small nœvoid spots of venous origin. On examination of the tumour by palpation, it is soft and non-resistant, while scattered through it are numbers of small, more or less indurated bodies suggestive of phleboliths. Obscure pulsation is perceptible in the mass, but it is evidently communicated to it from the vessels behind it. The patient says it commenced to grow six months ago, and that until that time from birth a small blue spot was the only abnormal appearance presented by the part. The tumour is attended by no prominent symptoms except occasional pain over its region, increased by handling, and having a neuralgic

character. His breathing is also rendered difficult at times. The theory of aneurism seems hardly tenable; while it probably may be a congenital hygroma which has recently taken on active development.

The Diseased Meat Trade under the Auspices of the Irish Local Government Board.

At the last meeting of the South Dublin Guardians a letter was read complaining of a statement made by one of the guardians, to this effect:—"The contractor for the purchase of cattle must be making a large profit, as the average cost of each animal was under £4 10s." It appeared that from the 20th July, 1882, to the 5th of April, 879 animals had been slaughtered for pleuro-pneumonia in the union. Of these 155 were sent to the knacker, and he had nothing to do with their prices; and the remaining 724 were sent to the butcher, for which an average of £5 14s. per head was received.

It will be almost incredible to our English readers that this beastly traffic in diseased meat is carried on openly in Dublin with the knowledge and apparent approval of the Irish Local Government Board. That the animals sold by the Irish Boards of Guardians are saturated with lung-fever is confessed, that the inspection of them to ascertain how far the disease has gone is perfunctory and insufficient is notorious, that the diseased meat so sold to the skink-butchers is re-sold by them to the poorer classes as good, sound, eatable meat, is manifest, and that the Guardians and the Irish Local Government Board are aware of the existence of this wicked trade is obvious from the fact that, within one union, 500 diseased beasts a year are sold at about one-sixth of the market price of sound meat.

When, not long since, we informed an official of the Cattle Department of the Privy Council that this trade in impure meat was carried on by Irish Boards of Guardians with the knowledge of the Irish Local Government Board, he could scarcely be induced to believe the statement, and he assured us that if the Privy Council had the least suspicion that a single diseased animal was sold by an English Board of Guardians, they would at once prosecute the Board.

It is monstrous and disgraceful, in the present condition of our knowledge of the transmission of fever germs, the Government Department whose duty it is to protect the Irish public against these proceedings, should connive at them as it does. Everyone knows the utter falsity of the theory that pleuro-pneumonic meat in any stage of the disease can be taken into the system without injurious results, and there can be little doubt that many of the 25 deaths from diarrhoea and dysentery, 206 from so-called convulsions, and 64 deaths from so-called typhoid, which occurred in Dublin within the last quarter, were due to the poisoning of the poor by the abominable carrion vended by the North and South Dublin Guardians. But, if this meat could be eaten safely, it would, nevertheless, be most disgraceful for any public body to lend itself to the making a profit of the sale of bad meat to the poor as good meat, and at the price of good meat. Such a transaction is roguery pure and simple.

The Council of the Irish College of Surgeons.

It seems probable that the general election of the Council next June will be hotly contested, if we may judge from the early appearance of candidates for seats on the governing body of the College. Dr. Tagert, formerly of Carrickmacross, now of Monkstown, co. Dublin, Dr. J. Bellow Kelly, of Drogheda, and Dr. Alcock Nixon, of Mercer's Hospital, have sent their cards of candidature to the Fellows. It is announced that Dr. Denham, a much-esteemed member of the Council, will not present himself for re-election.

Alcoholism in Children.

Those philosophers who annually assemble for the moral, social, and hygienic benefit of mankind in general, and in particular for their own mutual admiration and glorification, at the periodic feast of reason and flow of soul provided for them by the Social Science, and other similar congresses which now make autumn dreadful, are never weary of expatiating on the moral as well as physical improvements which, of late years, have been effected in the condition of our population. In reference to this we would crave liberty to say a few words by way of further comment on a case recently alluded to in this journal. We might, however, premise that, in some respects, the advancement thus claimed appears somewhat dubious. For example, at the present time, insanity as shown by the official reports of the number of registered lunatics now under supervision in England and Scotland as well as in Ireland, is nearly thrice more prevalent than was the case forty years ago. In the same way according to a recent writer, the proportion of scrofulous and tuberculous patients has largely increased in the practice of our hospitals. And in both instances the increase thus noticed appears to be to a considerable extent due to the great and increasing prevalence of alcoholism in all classes, in both sexes, and we regret to add at all ages, now coincidentally observed. The case under treatment in the Children's Hospital, Upper Temple Street, Dublin, where a boy, barely eight years of age, was recently admitted, suffering from well-marked *delirium a potu*, which nearly eventuated in the unfortunate child's death, might come as a not unfitting text for some observations on the terrible speed of intemperance now too apparent. In this instance the young inebriate was hereditarily predisposed to alcoholism. We believe that a full account of the case will probably be published by Dr. More Madden under whose care the patient was while in hospital, and we will not further dwell on it, but we may add that, the recklessness with which intoxicating drinks are supplied to the public and generally to all who can pay for them, even when as in this case, their customers are mere children, as well as to persons already drunk when entering the public house, urgently calls for inquiry and reform on medical as well as moral and social grounds. Very recently we saw three children, the age of the eldest of whom did not exceed ten or eleven years, in different states of intoxication reeling out of a public house in one of our principal thoroughfares on a Sunday

afternoon: one was unable to stand without the assistance of his companions, another was vomiting at the door of the gin palace, and all were uttering filthy imprecations, which under sad circumstances and in the voice of childhood were to us, not only the most pitiable of sounds, but also, the strongest appeal we had ever heard for some legal interference with that unholy traffic of which such were the results.

The Admission of Foreign Practitioners to Home Practice.

APROPOS of the proposition in the Medical Bill that foreign practitioners are to be admitted to practise in Great Britain if the Medical Council considers that their educational standard is sufficient, we notice that a new medical college has been organised in Cincinnati, under the title of the "Medical University of Ohio." This will make the *fourteenth* medical college in the State of Ohio. It would be interesting to know beforehand the method by which the Medical Council is to assess the educational status of the Medical University of Ohio, No. 14, and whether there is not a reasonable objection to the admission of the *alumni* of such an institution to the privileges of home practitioners whose status we know.

Notification of Infectious Diseases.

WE noted recently the fact that the medical practitioners of Brighton and Croydon are threatened with being put under the yoke of compulsory notification by virtue of private Bills which have been introduced to extend the system to those towns. These Bills have been remitted to the same committee of Parliament to which similar Bills were sent last year, and, if so, there can be no reasonable doubt that the Brighton and Croydon physicians will be put under "coercion," because the same committee last year refused to hear any evidence on the part of the profession, and passed these coercion Bills by a majority of one vote against the protests of the medical men of the towns to which the Bills referred. A still more alarming fact is that, within the last few days, the Lord Advocate and the Solicitor-General for Scotland have introduced a Bill to extend the compulsory notification system to the whole of the Scottish burghs, by which Bill every practitioner in Scotland residing in a municipality is put under a penalty of £2 for omission to notify. While these grievous encroachments on the rights of our profession are being made there does not seem to be any organisation in England or Scotland for mutual protection. The Parliamentary Bills Committee of the British Medical Association, which is supposed to have charge of the interests of medical men in England and Scotland, seems to have ceased to exist, or else its intelligence department has not yet arrived at the knowledge of these proceedings. It seems to us that unless the executive of the Association awakes to its duties, the members will shortly be in revolt against the mismanagement which has sacrificed their interests in this and other matters, and we trust that if it becomes necessary for the rank and file of the Association to take these matters into their own hands, they will not stop until they have executed a root and branch reform of the medico-political departments of the Association. If the Parliamentary

Bills Committee stands by and permits these Bills to pass without an effort to protect the profession, they will have to answer to the Association on the earliest public opportunity for having omitted to carry out the directions given by the members of the Association at Worcester and at Liverpool. At this moment medical men have to depend for protection against these Bills, not upon the executive of the British Medical Association, but upon the representatives in Parliament of the "Vigilance Association," an organisation weak in every sense, save that it possesses that earnestness and activity which the Parliamentary Bills Committee lacks.

A Yankee Definition of Chronic Bronchitis.

THE following is a ludicrous specimen of the Yankee method of speech as applied to therapeutics. The author of this peculiarly descriptive definition of chronic bronchitis is a Dr. Yount, of Lafayette, and the journal which gives him space for his lunatic lucubration is the *Canada Medical Record*:—

"'Winter cough' (says the writer) has been known for untold centuries. Nebuchadnezzar no doubt had this disease, for the physicians, after dosing him with villainous decoctions, nauseous infusions, and diabolical extracts, turned him out to grass. The chronic bronchitic then, as now, was a victim to be pitied.

"During the winter and spring months he sits in the house, in a snug corner, near a roaring fire, huddling together his skin and bones lest they get separated or lost. He sits there in his corner with his cuspidor handy, morose, dejected, and irritable to those around him. His face is pinched, and his colour yellow. In the summer, like a ground-hog, he comes from his hole, wrapped up in a thick ulster with fur collar, and cap drawn down over his ears, and his feet encased in large arctic overshoes. He walks slowly and swears rapidly at his ill-luck in having such a disease. He likes to tell how he feels, and gives all the blame for his illness to the weather and his liver."

If our Canadian contemporary could favour its readers with a portrait of the "ground-hog who comes from his hole wrapped in a thick ulster with fur collar, and cap drawn over his ears, and his feet encased in arctic overshoes," the pen and ink picture of Nebuchadnezzar would be complete.

WE note with satisfaction that Dr. J. A. Byrne, of Dublin, ex-President of the Dublin Obstetrical Society, has been elected an Honorary Fellow of the San Francisco Obstetrical Society.

DR. NORMAN KERR will deliver the inaugural address, as first president of the "Society for the Study and Cure of Inebriety," in the rooms of the Medical Society of London, on Friday next, at 3.30, when all members of the profession are invited to attend.

IN connection with the Hospital Association, Dr. Bristowe, F.R.S., and Miss Lückes will read papers this evening at 8 o'clock in the rooms of the Medical Society of London, entitled "How far should our Hospitals be Training Schools for Nurses."

Illicit Practice in France.

THE Abbe Maury, a priest in the parish of Cravens, has just been tried before the Police Tribunal of Saintes for illegally practising medicine. The offence was not denied, for a number of persons came forward to declare that he had cured them. The cure invoked in his defence an old decree of the Council of State which permits the rural clergy in urgent cases to give medical advice gratuitously. The Abbe Maury had made no charge for his consultations, and had only charged the cost of his medicines, but the Tribunal held that the offence had been proved, and sentenced him to pay a fine of 600 francs.

A Fever Hospital for Sunderland.

At a meeting in the Victoria Hall, Sunderland, on Wednesday last, the Mayor in the chair, the question of supplying the town with a special hospital for the treatment of fever patients was discussed, and a resolution affirming the necessity of such a step was carried unanimously. Among those who addressed the gathering was Dr. Abrath, who made a proposal to construct a number of separate temporary hospitals, to run on rails, the latter being furnished with a turntable for the purpose of facilitating the passage of air currents in various directions through the hospital. Dr. Mordey Douglas, in a long and able speech, explained the urgent necessity for forthwith carrying out the objects of the meeting. By his showing, existing provisions for treatment of fever cases are altogether inadequate to the wants created by emergencies, from experience of which Sunderland is, unfortunately, far from free. And so clearly was the necessity of removing the reproach in this connection from the town proved by Dr. Douglas, that it may be attributed to him that the resolution was carried in the way referred to. We trust that it may soon take practical effect.

Uterine Pathology.

DR. CLIFFORD ALLBUTT is an authority for whose opinions we entertain a high respect. His predictions always bear the stamp of a cultivated mind, comprehensive grasp of his subject, and the charm of honesty. In his Gulstonian Lectures, which during the past few weeks have been appearing in our columns, these characteristics are not wanting; and perhaps the best evidence of them is the fact that he has given offence in some quarters. For this everyone must make up his mind who enters certain departments of either medicine or surgery with the weapon of indignation against everything which has the semblance of quackery. Dr. Allbutt's remarks on uterine pathology will, however, find ready and grateful acceptance at the hands of all honest members of the profession—members who deplore alike the degradation of the medical calling, and, what is of even more consequence, the demoralisation of woman. How true it is, as pithily remarked by Dr. Allbutt, "Arraign the uterus, and you fix in the woman the arrow of hypochondria, it may be for life." How descriptive is his picture of the woman caught in the net of the gynaecologist, whose uterus, "like her nose, is a little on one side, or, again, like that organ, is running a little, or it is as flabby as her biceps, so that the unhappy viscus is impaled upon a

stem, or perched upon a prop, or is painted with carbolic acid every week in the year, except during the long vacation, when the gynaecologist is grouse-shooting or salmon-catching." Exception has been taken in high quarters to this manner of expression, but we overlook the airy humour in the presence of severe truth. How applicable is this to hyperborean regions, though Dr. Allbutt seems to have exclusively the metropolitan practitioner in his mind's eye. How happy is Dr. Allbutt's description of the under-educated and unscrupulous gynaecologist who, "looking only to the uterine organs, his reason bounded by the confines of the pelvis, attempts to stem the tide of general and diathetic maladies with little Partington mops of cotton-wool on the end of little sticks." Gynaecologists of this description are well known to us all. There are several reasons for the fascination which uterine pathology possesses for men of low talent, low morale, and high ambition. Uteri are pretty common; the practitioner's treatment and diagnosis are little liable to be supervised or checked; the emotional nature of the female is involved, and hence an unlimited scope is offered for unmitigated humbug. A species of martyrdom, especially in this relation, is very dear to many females, and a gossiping woman with an "inward complaint" is neither more nor less than a social nuisance.

There is, besides, fame to be reaped in the department of invention. The practitioner does not require to be much of a genius to be able to give a new twist to the blades of a forceps, a new valve to a speculum, invent a new uterine sound, or, though it may require more brain power, to add a new "bag" to the surgical Pantheon of the century.

We have every sympathy with Dr. Allbutt's opinions, and we commend his very able lectures to the closest consideration of our readers, and to all who have the moral and the social well-being of the profession at heart.

A Foreign View of our Adulteration Laws.

IN the Austrian Reichsrath, on the 14th ult., Abgeordneter Dr. Roser drew attention to the increase of adulteration of food stuffs and the spread of quackery in Austria, and alluded in the course of his remarks to England and the German Empire as countries in which stringent laws were in force against adulteration. He asked that the Government should appoint a Commission of experts to inquire into the subject. The Minister-President thought the existing regulations were sufficient to meet the requirements of the case. Our contemporary the *Wiener Allgemeine Medicinische Zeitung*, assuming such an alteration of the law to be possible, remarks that neither the Landes nor Ober-Sanitätärath, nor even the Stadtphysikat of Vienna possesses a proper chemical laboratory in which the necessary examinations of foods can be strictly carried out. With regard to his commendatory mention of England as a country in which the laws against adulteration are on a perfectly satisfactory footing, perhaps Dr. Roser is not aware that in this country a milk dealer may make £100 per annum by adulteration, and may safely calculate that even if successfully prosecuted, his fines and expenses of trial will not amount to more than £10 a year, leaving him a clear balance of £90. We do not consider this satisfactory.

Hope as a Remedy against Disease.

WE notice as a curious coincidence the appearance of Dr. J. Mortimer Granville's letter to the *Times*, Thursday, April 17th, under the above heading, coming as it does the day after the publication of a leader in our columns, April 16th, on the same subject, under the heading of "Hopefulness in Prognosis and Professional Manner—a Remedial Measure," it is at least singular, and affords another strong proof of how closely two persons can think and express themselves alike upon the same subject. Of course Dr. Granville's position and character render it impossible to regard the almost simultaneous appearance of his letter and our leader in any other light than that of a mere coincidence; but although pleased that his sentiments and ours are so strongly in union, we cannot help expressing regret that he should have chosen as his medium for their publication the columns of a lay newspaper, and that instead of seeking to impress them upon his medical brethren he should address them to the public generally. The doing so lays him open to the imputation of unworthy motives, however far such motives may be absent from his own mind.

Sham Medical Diplomas.

AN evening contemporary, usually well informed on matters medical, in its "Notes of the Day," on Saturday last, falls into the error of supposing or believing that because a person summoned before a Liverpool magistrate for falsely pretending to be a registered medical practitioner pleads that he holds a diploma of M.D. from "an authorised body in British Burmah" it really must be so. Now it is, or should be, known that there is no "authorised body" for granting diplomas in that part of the British Empire; no college that can legally confer a title to practise in any part of Great Britain. A document, it appears, was produced in court, and from this fact the editor argues that "the real question at stake is whether a diploma granted in one part of the British Empire has authority in all parts? and if, for instance, it was decided that a Burmese diploma does not entitle its holder to append the letters M.D. to his name in England, it would be open to the Burmese authorities to retaliate by refusing to recognise the validity of British diplomas." Now all this fine writing exhibits a lamentable amount of ignorance of British law bearing on the point, and also of the Medical Act, which we commend for perusal.

The individual whose prosecution was last week undertaken by the Liverpool Medical Defence Association (De Tomazie, an Asiatic, practising as "M.D. Ind." in West Derby Street, Liverpool) is the same who was successfully prosecuted two years ago for a similar offence, and the only difference in defence on the two occasions was that on the first the defendant was not able to produce a "diploma," and on the second he was able to do so. The learned stipendiary confessed that he did not know the worth of the "M.D. Ind. diploma" produced, and the prosecution do not appear to have been able to prove its worthlessness. That it is worthless no reasonable being can doubt, but this is a different thing to affording proof. On this point the prosecution were clearly at fault and they failed because

the case was not thoroughly got up, and not because of any inherent weakness in it.

The letters "Ind." after the M.D. can clearly have no effect one way or another. They have absolutely no meaning. An American would perhaps take them to mean Indiana, but to English people they might just as properly be taken to stand for "indecent," "indelicate," or a host of other things. We look upon the failure of the prosecution as unfortunate from more than one point of view, one point not the least in importance being that the public will be seen to look upon an unsuccessful prosecution of this kind as prosecution set on foot by professional jealousy.

PROFESSOR EILHARD SCHULZE, of Graz, has been called to the Chair of Comparative Anatomy in the Berlin University.

PROFESSOR TOLDT, of Prague, has been called to the Professorship of Anatomy in Vienna. He is not expected to commence his new duties, however, until the next winter session.

MR. FRANCIS HIRD, F.R.C.S., was a few days since presented with an illuminated address and a service of plate by his colleagues and former pupils of Charing Cross Hospital, upon his retirement from the office of Dean of the Medical School. Mr. Hird's services to the Hospital extend over a period of forty-five years.

THE office of Conservator to the Royal College of Surgeons of England having become vacant in consequence of the transference of Prof. Flower to the British Museum, the Council are prepared to receive applications from candidates for the appointment up to May 3rd. The honorarium attached is £600 per annum and a residence near the College.

DR. KOCH and the members of the German Commission sent last autumn to Egypt and India to investigate the cause of cholera, have arrived at Alexandria on their return to Europe. Their opinion is that as there is no appearance of cholera in Egypt at the time of the first intense heat the country will this year remain free from the epidemic.

In the list of the members of our profession who hold the Commission of the Peace in Ireland, we inadvertently omitted mention of our brethren who hold the magistracy for the City of Dublin—viz., Sir George Owens, who served the Lord Mayoralty in 1876, and the High Shrievalty in 1881; Dr. William Carte, of the Royal Hospital; and Dr. Long, of the Dublin Town Council.

In the principal foreign cities the rates of mortality per 1,000 of the various populations were, according to the latest official returns, as follow:—Calcutta 29, Bombay 25, Madras 62, Paris 29, Geneva 40, Brussels 27, Amsterdam 30, Rotterdam 24, The Hague 25, Copenhagen 21, Stockholm 24, Christiania 18, St. Petersburg 39, Berlin 22, Hamburg 27, Dresden 22, Breslau 37, Munich 36, Vienna 27, Prague 42, Buda-Pesth 33, Trieste 29.

Rome 34, Turin 39, Venice 21, Lisbon 38, New York 24, Brooklyn 22, Philadelphia 21, and Baltimore 20.

THE deaths registered last week in the principal large towns of the United Kingdom corresponded to an annual rate of 20·4 per 1,000 of their aggregate population. The death-rates in the several towns were:—Leicester 14; Bristol, Huddersfield 15; Sheffield 16; Bradford 18; London, Plymouth 19; Portsmouth, Leeds, Birmingham, Derby 20; Bolton, Birkenhead, Nottingham, Norwich 21; Blackburn, Newcastle-on-Tyne, Salford, Liverpool, Edinburgh, Sunderland 22; Dublin, Preston, Hull, Oldham 23; Brighton 24; Manchester 25; Glasgow 28; Cardiff, Halifax 30; Wolverhampton 31.

THE highest annual death-rates from diseases of the zymotic class in the large towns last week were—From whooping-cough, 1·9 in Salford and in Bolton, 1·7 in Liverpool, and 1·6 in London; from measles, 4·3 in Portsmouth, 2·6 in Oldham, 2·2 in Leeds, and 2·0 in Wolverhampton; from scarlet fever, 1·7 in Newcastle-upon-Tyne, 1·6 in Sheffield, and 1·3 in Leeds; and from "fever," 1·0 in Bolton. The 35 deaths from diphtheria included 17 in London, 7 in Glasgow, and 2 each in Portsmouth, Leicester, Leeds, and Cardiff. Small-pox caused 8 deaths in London, 4 in Liverpool, 3 in Newcastle-upon-Tyne, 2 each in Birmingham, Sheffield, and Sunderland, and 1 each in Derby and Hull.

Scotland.

[FROM OUR NORTHERN CORRESPONDENTS.]

UTERINE THERAPEUTICS.—DR. BELL'S TAMPON.—Dr. Robert Bell, of Glasgow, is an irrepressible exponent of peculiar views in connection with the treatment of certain uterine affections. By means of what he calls a medicated tampon, which consists of lint saturated with alum and glycerine, he seems to have reduced uterine therapeutics within very narrow limits. Unfortunately, however, his zeal and belief in the virtue of the agency in question, fail to make converts. Some two years ago, he read a paper on the subject before the Edinburgh Obstetrical Society, and it was received with mixed feelings of surprise and incredulity. Nothing daunted, he recently returned to the subject; and it is gratifying to note that he publicly informs the profession through the Edinburgh Obstetrical Society, that since his former appearance he has "had reason to modify his views very considerably." On this Dr. Bell is to be congratulated; and doubtless the announcement was refreshing to our Edinburgh *confrères*, if they are at all susceptible to influences which agitate higher spheres under like circumstances. In the discussion which followed the reading of Dr. Bell's paper, Dr. Angus MacDonald naively remarked "In his last communication Dr. Bell expressed his belief that his tampon could absorb fibroids, Dr. MacDonald was glad to notice no such claim made in the present paper. He had tried it conscientiously, but he had never succeeded in producing any permanent effect which he could attribute to the tampon." Professor Simpson "agreed with Dr. MacDonald in his low estimate of the value of this method of treatment." Surely Dr. Bell must now have quite enough of the Edinburgh Obstetrical Society, and *vice versa*!

UNIVERSITY MONOPOLY IN TEACHING.—In an able leader, with which we cordially agree, our contemporary the *Glasgow Herald* makes the following just remarks on the monopoly in teaching possessed by the Universities:—"To speak plainly, in the public interest, the University of Edinburgh enjoys a practical monopoly of medical education which is contrary to the spirit of fair play, and which is certainly adverse to the best interests of the University itself. So long as Professors examine their own students for degrees so long will the extra-mural lecturers be practically shut out of the field, except in those cases in which the extra-mural lecturer has had the good fortune to be elected assistant-examiner in the University. But this latter feature is rarely seen in Edinburgh. Strangers more (or less) distinguished are chosen; and the unenviable spirit which ignored the Medical School at the Tercentenary celebration repeats itself in all the relations of the University to its extra-mural rival."

EDINBURGH.—HEALTH OF THE CITY.—The mortality in Edinburgh for the week ending with Saturday, the 12th inst., was 100, and the death-rate 21 per 1,000 per annum. There were 25 deaths under 1 year and 16 above 60, of which 1 was above 90 years. Diseases of the chest accounted for at least 50 deaths, and zymotic causes for 15, of which 13 were due to whooping-cough, 1 to scarlatina, and 1 to measles, the intimations of these two diseases during the week being 27 and 62 respectively.

DEATH OF DR. JAMES PATTERSON CASSELLS.—We sincerely regret to announce the death of Dr. James P. Cassells, which occurred on the 13th inst., at Mount Florida, Glasgow, at the age of 48. Dr. Cassells was well known in the Anderston district, where he formerly practised as a general practitioner. A few years ago he took up the speciality of aural surgery, and founding the Glasgow Ear Hospital, secured a large and lucrative practice. He wrote many papers on Aural Surgery, and his name has been prominently associated with the recent translation of Politzer's classical treatise "On Diseases of the Ear," and Professor Hartmann's "Deaf-mutism and the Education of Deaf-mutes," both of which have been well received by the profession.

OUTBREAK OF FEVER IN PAISLEY.—An outbreak of fever has taken place in this town, owing to defective sanitary and drainage arrangements. The sanitary authority has taken all care to suppress the outbreak, which was beginning to assume large proportions. There are now 38 cases of fever in the hospital, the greatest number that has been in the hospital for a goodly number of years. In fact, the hospital is crowded, and some cases have to be accommodated in the old hospital.

MORTALITY IN GLASGOW.—The deaths in Glasgow during the week ending with Saturday, the 12th inst., were at the rate of 29 per 1,000 per annum of the population, as compared with 26 in the previous week, and 34, 27, and 26 in the corresponding periods of 1883, 1882, and 1881 respectively.

TERCENTENARY GOSSIP.

THE Tercentenary celebration of the University of Edinburgh has come and gone. The notables from all parts of the world, like meteors, have flashed across the horizon, and like meteors, have vanished, leaving a long train behind them, which is not likely to be forgotten for many a long day. Never has Edinburgh entertained so distinguished an assemblage, or displayed such right royal welcome to those who came as her invited guests to do honour to her noble University.

THE celebration commenced on Tuesday, as was meet it should be, by a reception by the City Fathers in the Museum of Science and Arts of the guests who had come to take part in the general rejoicing. The Lord Provost and Town Council in their civic robes received the guests, who filed in for nearly two hours in one continuous stream. The crush at times was very great, but where all was good nature and amiability, little inconvenience was experienced.

ON Wednesday the fine old cathedral of St. Giles, recently restored to its pristine grandeur by the late Dr. William Chambers, was crowded with a large audience. At a quarter to eleven o'clock the grand procession of notables and professors entered the church and took the seats assigned to them. Then followed the religious service, the sermon being preached by Professor Flint. To many who remembered the cold, barn-like interior of a Scottish kirk of their youth, the scene before them must have awakened strange thoughts. The gay and in many cases elaborate robes of the Academic visitors, with here and there the bright uniform of the military, formed a *mise-en-scène* not readily to be forgotten. The building is not well fitted for hearing, and the echoes in many parts quite drowned the voice of the preacher. The thought persistently arose that the old ceremonial religion which for so many centuries has been banished from the ancient pile may yet return, and that at an earlier date than many present would be inclined to admit.

THE service finished, the luncheon furnished by the Medical Faculty of the University followed. This was held in the new anatomical museum, which, as Sir James Paget remarked, could not be put to a better, or to a more fitting purpose in the future, for the education of the students who, he hoped, would still continue to flow to Edinburgh. The Medical Faculty and their Dean are to be congratulated on the satisfactory result of their efforts. The Extra-Mural Medical School was well represented, and we trust that for the future the two schools, neglecting side issues, will work together for the common weal of both.

OMITTING any notice of the numerous other entertainments in honour of the assembled guests, the most imposing meeting next to that in St. Giles' Cathedral—we should have called it Kirk—was the Tercentenary graduation ceremonial. The first item on the programme was the reception of delegates from the Universities and other learned bodies. These were received by the Lord Chancellor. Seventy-five Universities sent delegates, and fifty-three came from other learned bodies. Many of the delegates presented addresses prepared in the most elaborate manner, some in the form of richly-bound volumes, some in cases which looked like gigantic cases containing Pears' matchless shaving soap. Then followed the conferring of honorary degrees, the recipients of which each came in for a share of applause. Among those of whom special notice was taken we may mention M. Louis Pasteur, M. Ferdinand de Lesseps, Professors Virchow, Pettenkofer, Helmholtz, and Jowett. Dr. Martineau and Principal Tulloch, amongst those who received the degree of D.D., were most cheered. We have before given a list of the delegates and honorary graduates, so need not repeat them here. The Chancellor then closed the meeting with an address in which he gave a short sketch of the origin and progress of the University. In the midst of the proceedings a telegram was received from the Prince of Wales conveying his congratulations to the University. At the banquet a similar telegram was also received from the Queen, dated Flushing. Both were received with repeated applause, and the gracious message of Her Majesty has created a profound feeling here, especially

when the sad ordeal through which she has so recently passed is remembered.

As is usual wherever Britons celebrate anything, a banquet brought the Tercentenary celebration to a close, and Edinburgh has relapsed into its every-day appearance, as if nothing had happened or been happening for the last week.

PROFESSOR VIRCHOW AT THE TERCENTENARY.

AMONG the very able Tercentenary addresses delivered last week in Edinburgh, the following, by Professor Virchow, is notable as possessing special medical interest. The speech was in German, of which the following is a translation:—

In considering what to say that might be of interest to a group of students, I remembered that I would be speaking in this hall, not only to Scotland, but to England, Ireland, the Colonies, and the whole English-speaking world. I knew that great subjects were discussed in your University, in the wide range of which the teachings of this school were largely in accordance with my own. Among the matters which have a common interest for us, I am in such cordial sympathy with you that there is only one topic on which there may seem to have been some disturbance in the happy relation which subsists between us. On that matter, therefore, you will allow me now to speak to you—I mean the position which I am supposed to have taken up towards the teachings of Darwin. The opinions which I expressed have, in some English publications, been much misunderstood. I never was hostile to Darwin—never have said that Darwinism was a scientific impossibility. But at that time, when I pronounced my opinion on Darwinism at the Association of German Naturalists at Munich I was convinced, and still am, that the development which it had taken in Germany was extreme and arbitrary. Allow me to state to you the reasons on which I founded my opinion. Firstly, Darwinism was interpreted in Germany as including the question of the first origin in life, not merely its manner of propagation. Whoever investigates the subject of development comes upon the question of the creation of life. This was not a new question. It is the old *generatio equivoca*, or *Epigenesis*. Does life arise from a peculiar arrangement of inorganic atoms under certain conditions? We can imagine oxygen, hydrogen, carbon, and nitrogen coming together to form albumen, and that out of the albumen there was produced a living cell. All this is possible, but the highest possibility is only a speculation, and cannot be admitted as the basis of a doctrine. In science it is not hypotheses that decide, but facts; we arrive at truth only by investigation and experiment. I need not say that this demand of science for proof instead of speculation was long ago made in England. Ever since the time of Bacon it has had a home amongst you. In recent times the fact of the presence of minute organisms giving rise to important processes has been recognised, not only in medicine, but in connection with agriculture and various industries. It was of the utmost importance to determine whether these organisms were originated *de novo* in the decomposing bodies, or were produced by similar pre-existing organisms, and introduced from without. A century ago it was possible to admit the spontaneous generation of microbia. But here sits M. Pasteur, the man who has demonstrated by means of direct experiment that, in spite of all logical possibility, all known microbia found in decaying matter are derived from similar ancestors. No man would now be justified in practical life in acting on the possibility of a *generatio equivoca* of microbia. A physician who finds himself in presence of infectious disease among his patients, or an agriculturist whose crops are blighted, or a man engaged in the production of alcohol or sugar by fermentation, must set himself to discover what brings about the changes that he has to deal with; he must see that organisms are there which have been imported from without, and must then inquire whence they have been derived. The physician who has to combat an epidemic dare not act as if the germ were spontaneously produced in any patient. Such is the difference between logical possibilities and the practical work of daily life. Every teacher of science must lead his students to suppose that each living being that he meets must have had a father and mother, or at least one or other of them; and every scientific conclusion maintains that one generation is legitimately descended from another precisely similar. That was one consideration that led me to warn my fellow-countrymen against developing a system out of logical possibilities.

At the very time when we were getting free from the chains of former dogma, we seemed to be in danger of forging new ones for ourselves. The second question concerning Darwinism had regard to the descent of man, whether from apes or other vertebrate animal. Was there anywhere a pro-anthropos? In regard to this question, I thought that the existence of such a precursor of man was a logical possibility, perhaps a probability. Only I found, to begin with, that it was a purely speculative question; not one raised by any observed phenomenon. No pro-anthropos had ever been discovered, not even a fragment of him. I had myself long been specially occupied in making pre-historic investigation to get near the primitive man. When I began these studies, twenty years ago, there was a general disposition to arrive at this discovery. Everybody who found a skull in a cave or a bone in the fissure of a rock thought he had got a bit of him. I wish you specially to notice that the smaller the fragment of skull, the easier it was to make it out to be the skull of the pro-anthropos. It was never thought of where the entire skull was in hand. When the upper part of the cranium alone—the calvarium without the face and the base, as in the case of the Neanderthal skull—was discovered, it was easy, by changing its horizontal position, by elevating either the anterior or posterior part, to give the impression that it had belonged either to a being of a superior or inferior race. You can make the experiment with any calvarium. If you make a series of diagrams of skulls, placing them over each other, you may make them appear similar or dissimilar, according as you choose one or another fixed point for bringing them into relation. I should like to impress upon you that every discovery of that kind should be received with caution and scrutiny. In my judgment no skull hitherto discovered can be regarded as that of a predecessor of man. In the course of the last fifteen years we have had opportunity to examine skulls of all the various races of mankind—even of the most savage tribes—and among them all no group has been observed differing in its essential characters from the general human type. So that I must say that an anthropological teacher has not occasion to speak of a pro-anthropos except as a matter of speculation. But speculation in general is unprofitable. The day before I gave the address in Munich to which I have referred, Haeckel had gone so far as to propose to introduce into our schools a new system of religious instruction, based upon the doctrine of the "Descent of Man;" and I still think it necessary to guard against the danger of constructing systems of doctrine out of possibilities, and making these the basis of general education. Lastly, I have to refer to the geological aspect of the question. This is the most important aspect of it as treated by Darwin himself; and here we must recognise that the most important advance has been made in consequence of his ideas in our understanding of the progressive development of organs in the different classes of animals. From the earliest period the organisation of man has been regarded, and can only be regarded, as an animal organisation; and, therefore, from a zoological point of view, the body of a man must be regarded as belonging to the animal kingdom. That I do not wish to deny. This day ten years ago Liebig died. I recall his memory at this moment to repeat one of his memorable sayings—"Natural science is modest." He meant that science should be confined within the limits of observation. Every man who goes beyond that sphere becomes a transcendentalist, and transcendentalism has always been dangerous to science.

DR. ROGERS AND THE WESTMINSTER GUARDIANS.

IN our issue of October 31st, 1883, we drew attention to the suspension of Dr. Joseph Rogers, the Medical Officer of the Westminster Union Workhouse, who, as we then pointed out, had exerted himself for a long series of years in advocating the interests of the sick poor and of the Poor-law Medical Service, not in England alone, but in Ireland and Scotland, to which portions of the United Kingdom he had made repeated visits with the object of pressing forward their claims for larger consideration. Dr. Rogers, so we learn, some two and a-half years ago, was compelled to report the misconduct of the Matron. On investigation his allegation against her was sustained, and the woman was ordered to be admonished. From that time until October 1882, Dr. Rogers was exposed to a continuous system of annoyance, and refusals on the part of the Master and Matron to carry out his orders for the sick, accompanied on the part of the Master by the use of

blasphemous language. Dr. Rogers thereupon appealed to the Inspector, Mr. Robert Hedley, for his intervention, but only to meet from that official the most supercilious and objectionable treatment. Ultimately he placed documentary evidence in the hands of Mr. W. J. Fraser, solicitor, of Soho Square, one of the members of the Board, showing how he was prevented from doing his duty. Mr. Fraser brought the facts before the Board of Guardians, and asked for an inquiry, when he was absolutely hooted down; not being discouraged thereby, he, in conjunction with two of his colleagues, who supported him, drew up a presentment against the Master, and forwarded the same to the Local Government Board. Following the course always adopted by the department, a copy of their letter was sent to the Guardians, who immediately turned on their colleagues and passed a resolution "that they were unfit to associate with gentlemen," that is, the gentlemen of that Board. But as they had been asked to inquire into the truth of the charges they were compelled so to do. The inquiries were entered upon, when, as might have been expected, the Master was acquitted, and his accusers, from Dr. Rogers down to the humblest inmate, were stigmatised as slanderers. Notwithstanding this, the three insisted on an official inquiry, and Mr. Robert Hedley and an assessor were appointed to conduct it. The inquiry lasted ten and a-half days, and in the course of it evidence was adduced of continuous use of blasphemous language, personal violence to, and general maltreatment of, the aged and other inmates, by the Master, and of fraudulent entries of wines and spirits by the Matron and Master's clerk, in the medical officer's portion of the relief book, never ordered by the Doctor nor supplied to the sick.

The charges were clearly established, and the discharge of the Master appeared inevitable, when, to the surprise of all, it came out that Mr. R. Hedley, the Government Inspector, had recommended Sir C. Dilke, the President of the Local Government Board, to allow the Master to remain, to which, so we understand, the President very reluctantly acceded. Emboldened by this, the majority of the guardians at once commenced a system of reprisals against the medical officer; at first they called on him peremptorily to resign: on Dr. Rogers declining to do this, they, after an interval, suspended him from his office on charges as frivolous as they were malicious. The majority evidently relied on the fact that as Mr. Hedley had advised the retention of the Master that he would support their desire to get rid of the doctor, and there can be no doubt that with any ordinary medical officer such would have been the fate meted out to him, but they reckoned wrongly.

Dr. Rogers has made, during a public life of nearly forty years, many powerful political friends, and he was not to be disposed of so easily. He invoked the aid of those friends, and the malice of the majority of the guardians and the sympathy of Mr. R. Hedley with the views of the said majority were unavailing. Dr. Rogers was reinstated, but his reinstatement was accompanied by a most insulting letter, which we have good reason to believe was written by the baffled inspector. This, we learn, will yet be inquired into.

During his suspension Dr. Rogers used the spare time afforded him in working up an opposition to the majority of the guardians who had so unjustly suspended and insulted him. In that action he was supported, not only by the strength of his own cause, but by the fact that the Master of the workhouse had so acted in his position as to evoke antagonism from lady and other visitors, subordinate officers, and many inmates. This, coupled with his proved delinquencies, at the official inquiry, caused such a feeling of indignation as led to several gentlemen of position agreeing to stand as guardians. Their candidature was supported by the nobility, leading tradesmen, and clergy in St. James's, and by the leading tradesmen, clergy of all denominations, and others in St. Anne's. This uprising eventuated in the ignominious expulsion from office of the thirteen guardians who had supported the Master and persecuted the doctor, and their replacement by a new Board.

It is not the least of the triumphs achieved by Dr. Rogers that he has succeeded, not only in vindicating his own position, but of inflicting condign punishment on his opponents. It is, however, melancholy to reflect that our Central Government control should be so ineffective that one official, to wit, Mr. Robert Hedley, should through his partiality and perversity have rendered such an indignant uprising necessary; but *magna est veritas et prevalebit*.

Medical News.

The Royal Institution.—The following are the lecture arrangements for April and May:—Dr. Klein, two lectures on the Anatomy of Nerve and Muscle, on Tuesdays, April 22nd and 29th; Professor Gamgee, five lectures on the Physiology of Nerve and Muscle, on Tuesdays, May 6th to June 3rd; Professor Dewar, seven lectures on Flame and Oxidation, on Thursdays, April 24th to June 5th; Mr. Hodder M. Westropp, three lectures on Recent Discoveries in Roman Archaeology, on Saturdays, April 26th to May 10th; and Professor I. G. Bonney, four lectures on the Bearing of Microscopical Research upon some large Geological Problems, on Saturdays, May 17th to June 7th. The Friday evening meetings begin on April 25th, when Mr. Walter Besant is to give a discourse on the Art of Fiction.

The Parkes Museum of Hygiene.—At a meeting of the Council, held on the 9th inst., Dr. G. V. Poore in the chair, the following gentlemen were elected members:—Right Hon. Sir Charles Dilke, Bart., M.P.; Sir Spencer Wells, Bart.; Sir Thomas H. Farrer; Sir Henry Thring, K.C.B.; Mr. W. Cornwallis Cartwright, M.P.; Mr. Francis Galton, F.R.S.; Dr. W. Rath, Surgeon-General, Saxon Army; Mr. Octavius Hansard, F.R.I.B.A.; Mr. Arthur Cates, F.R.I.B.A.; Mr. Charles Barrey, F.S.A.; Dr. Hubert Airy; Dr. C. S. Paget, M.O.H.; Mr. J. Douglas Matthews, F.R.I.B.A.; Mr. Ernest Turner, F.R.I.B.A.; Dr. G. D'Arcy Adams; Mr. Benjamin Baker, C.E.; Mr. Charles Hancock; Mr. Shadworth H. Hodgson; Mr. A. McMarren; Mr. Monier Williams. During the past month there have been 51 new members elected.

Ledwich School of Medicine, Dublin.—The following students at this College were awarded prizes at the termination of the winter session:—Practice of Medicine: John Donaldson, 1st; A. Digges La Touche, 2nd. Surgery: G. Woods, 1st; H. Morrison, 2nd. Senior Anatomy: Shirley Roberts, 1st; J. W. Patrick, 2nd. Junior Anatomy: R. J. Hewitt and T. O. Williams, equal. Physiology: H. Morrison, 1st; Shirley Roberts, 2nd. Chemistry: Henry Breen, 1st; T. S. Siles and Thomas Browning, equal. Midwifery: John Donaldson, 1st; W. E. Lambert, 2nd.

South London School of Pharmacy, 325 Kennington Road.—The following prizes were presented to the successful competitors on Saturday, the 19th April, 1884:—Senior Chemistry:—*Medal*: F. Armstrong; *Certificate*: F. W. Ashton. Junior Chemistry:—*Medal*: Thos. B. Blyton; *Certificates (equal)*: F. W. Taylor, W. Holme. Botany:—*Medal*: R. M. Stewart; *Certificate*: G. D. Cooper. Materia Medica:—*Medal*: R. M. Stewart; *Certificate*: T. J. Clark. Practical Pharmacy and Dispensing:—*Medal*: T. A. Moss; *Certificate*: R. M. Stewart. *Extra Certificates*: Messrs. Atherton, Buxton, French, Hall, and Worfolk.

Pass Lists.

University of Glasgow.—*Degrees of M.B. and C.M.*—The following candidates have passed the first professional examination (Natural History, Botany, and Chemistry):—

Frederick Ashurst, Charles Banks, James A. Brown, James Bruce, Alexander Butler, Saxon S. Dale, Thomas T. Downie, David Elliot, William R. Forrester, William Gemmell, Andrew Gray, Harry Gray, Archibald Gunn, Edward O. Harrison, E. C. Hight, G. F. Hillard, Robert Hogg, Arthur D. Hughes, George J. Imrie, John A. Jackson, Thomas Kirkland, James Marshall, William Marshall, Thomas L. Macfarlane, Robert M'Ghie, George M'Intyre, C. A. Mackenzie, William T. Nicholson, Hugh Rhodes, Henry W. Robinson, William P. Sandilands, Charles E. Scanlan, Henry W. Sinclair, J. W. H. Stell, Robert Stevenson, Edward B. Tant, James A. Ure, and Andrew S. Wotherpoon.

The following candidates have passed the second professional examination (Anatomy and Physiology):—

William M. Alexander, M.A., John Allan, W. Carrick Allan, Samuel J. Baird, Charles William Bell, H. Duncan Brown, Alexander Bryce, William Butchart, M.A., Archibald T. Campbell, Robert Craik, William C. Crichton, John Currie, George W. Davis, J. L. Downs, William J. Giblin, John R. Gibson, John D. Gordon, Charles Gray, Yousof Hamis, Walter Hay, Herbert Hickie, John Hogg, James E. Hunter, William Huntly, M.A., George Marshall, J. G. Marshall, Alfred E. Miller, George Miller, Donald S. MacColl, J. R. R. M'Crindle, Tom Macdonald, John M'Keith, Archibald Macleachlan, William M'Millan, Charles M'Taggart, M.A., Andrew H. Richmond, John Ritchie, John Rowat, Thomas Rutherford, B.A., David Stiel, James Watson, Leonard Williams, James Wilson, M.A., William Yorke, and Robert R. Young. J. W. Shane passed the Second Examination, old Regulations Anatomy, Physiology, and Zoology).

The following candidates have passed the third professional examination (Regional Anatomy, Materia Medica and Pharmacy, and Pathology):—

Archibald S. Alexander, Samuel P. Alexander, William Allan, Alex. M. Bankier, John Broom, Hugh D. Buchanan, John Buchanan, J. Wilson Cameron, William D. Campbell, Quintia Chalmers, Robert Cook, Charles Court, B. S. Cowen, David K. Cross, William Cullen, Henry E. N. Doble, John Doid, James Dunlop, M.A., Robert Eaglesham, Robert M. Fleming, Robert O. Gilroy, John Graham, Ernest W. Haydon, Wm. J. Holme, John Hughes, Hugh Kelly, John A. Kerr, William Kirkland, Trafford Mitchell, Wm. C. C. Muir, James I. Macarthur, Thomas C. M'Culloch, John A. Macdonald, Roderick Macdonald, Digby M. Macphail, Alexander M. Macrae, Henry J. Neilson, James Parker, W. Whiteside Paterson, Andrew Richmond, David Roxburgh, Walter Sandeman, Wm. M. Sample, William Seright, Robert M. Service, William Shand, Walter W. Spence, Charles D. Temple, Allan Watt, Charles Whish, John White, Andrew Wilson, James Wilson, John S. Wright.

University of Aberdeen.—The following candidates having passed the necessary examinations, received their degrees at the late graduation ceremonial. The degree of M.D.:—

Alexander Theodore Brand, M.B., C.B., Driffield; William Carnegie, M.B., C.M., Penang; Sylvester William Pinclater, M.B., C.M., Dufftown; Timothy Siddall Jones, M.B., C.M., Swansea; James Millar, M.B., C.M., Arbroath; John Hay Moir, M.B., C.M., Burton-on-Trent; Charles Lloyd Tuckey, M.B., C.M., London; James Hutchison Walker, M.A., M.B., C.M., North Borneo.

The following candidates received the degrees of M.B. and C.M.:—

Henry M'Kenzie Adamson, Morphis, Montrose; George Henry Allden, Southampton; John Hector Anderson, Aberdeen; Joseph Anderson, Preston; Albert Henry Barrett, Wallingford, Berks; Christopher George Battiscombe, Blackheath; Francis Alexander Bennett, M.A., Cullen; William R. Donaldson Clark, M.A., Edinburgh; James Will Cook, Alnsea; Alexander Mitchell Cowie, Mortlach; James Forsyth Craig, M.A., Leslie, Inch; George Burnett Currie, M.A., Aberdeen; Henry Moxor Cyril Dalton, Newcastle, New South Wales; George Duffus, Cullen; Walter Angus Elmie, Beattot; Charles Albert Faulkner, Rajahmundry; John Andrew Fearn, Graaf Reinet, South Africa; William Revelly Forster, Blyth, Northumberland; John Gordon, Keith; Thomas Bell Graham, Ecclefechan; Andrew Grant, Balmoral; John William Harrison, Sandwich; Charles Robert Lyall, Aberdeen; Stuart Macdonald, Elgin; Frank James Mackintosh, M.A., Deskford; Alexander Maclean, F.R.C.S. Ed., Thurso; George Milne, Methlic; James Mitchell, Aberdeen; James Mitchell Munro, Inverurie; Alexander Murchison, Lochearn; Eneas Poonan, B.A., India; Robert Dowell Presslie, Aberdeen; Alfred Ernest Roberts, London; William Robertson, M.A., Rathen; William Ledingham Ruston, Wakefield; James Savage, Montrose; William Leith Irel and Sutherland, Aberdeen; Herman Thiele, Bermuda; Leslie Pyfe Walker, Aberdeen; John Eustace Webb, Windsor; James Will, Elton; John Thomas Windle, Banaley. Received their degrees with honourable distinction.

The John Murray Medal and Scholarship was awarded to Arthur Greatorex Smith. At the same time, the following candidate was certified as having passed all the examinations, but did not graduate:—Arthur Stephen Inglis.

Notices to Correspondents.

CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a *distinctive signature or initials*, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

LOCAL REPORTS AND NEWS.—Correspondents desirous of drawing attention to these are requested kindly to mark the newspapers when sending them to the Editor.

READING CASES.—Cloth board cases, gilt-lettered, containing 26 strings for holding each volume of the *Medical Press and Circular*, may now be had at either office of this Journal, price 2s. 6d. These cases will be found very useful to keep each weekly number intact, clean, and flat after it has passed through the post.

THE APPOINTMENT OF HOUSE SURGEON TO AN HOSPITAL: WHAT IS ITS PRACTICAL VALUE?

To the Editor of the MEDICAL PRESS AND CIRCULAR.

SIR,—So frequently have I been asked by the hospital students as to the course that they should pursue immediately after obtaining their diplomas, and so often have I recommended them to try and obtain a house surgeoncy in preference to anything else, that I shall feel obliged by your giving insertion to the following table of accidents, injuries, and diseases, with their necessary operations, occurring in a period of a little over eighteen months. It illustrates well the amount of experience that any young surgeon may gain, if fortunate enough to obtain such an appointment. To the late resident surgeon of the City of Dublin Hospital I am indebted for its compilation, and for permission to forward it to you for publication in the *Medical Press*. The cases and operations therein set down came under his immediate care during a portion only of his period of duty, and I believe that any young surgeon will allow (after reading the details given) how fully it

has borne out my views, and justified me in recommending a house surgery as a field of study, if, by any possibility, the student can obtain an appointment of the kind.

Yours, &c.

JOLLIFFE TUFFELL,

Consulting Surgeon to the City of Dublin Hospital.

[We regret we cannot give space for the extended list sent us. It includes: Amputations, 66; excisions, 138; fractures, 412; dislocations, 22; other operations, many of them capital, 1,070—total, 1,708. These were operations performed, not merely in the hospital, but in the presence of the house surgeon, and there can be no question that such experience would be simply invaluable in after-life.—ED.]

STRUMA.—Recent publications on the subject of acrofula are few in number. The chief is Mr. Treves' work, entitled "Scrofula and its Gland Disease." This gentleman is also author of the operation on the spine about which you make inquiry.

R. F. G.—The office is an annual one, but it is usual for the holder to obtain re-election in each of the three or four years succeeding his first appointment.

THE BOYCOTTING OF MEDICAL ASSISTANTS.

To the Editor of the MEDICAL PRESS AND CIRCULAR.

SIR,—I have read with care and some astonishment the replies and comments which my letter has elicited. Some of your correspondents dispute the accuracy of my statements, others impute motives. The latter I think I need not notice, especially when I note the *animus* of the writers. With regard to the former, let me at once say that I should be very glad to have my statements shown to be erroneous, but letters now lying before me testify to the unfortunate accuracy of my views; and the members of my *locum tenens* staff, on returning from duties in all parts of the country, confirm what is stated in letters. If the contrary position be true, then the demand for Irish gentlemen ought to give a great impetus to the business arrangements referred to by one of your correspondents, whose applications from English employers ought to be in excess of the supply which he can command. I do my utmost to remove the stupid prejudice to which I refer, and in many cases I succeed.

I think that I need not point out the illogical inference that because a few men are assassins therefore their nation is murderous. As a personal friend of the late Daniel O'Connell, Smith O'Brien, and others, I need scarcely say in which direction my sympathies go.

50 Lincoln's Inn Fields,

April 16, 1884.

Yours, &c.

J. BAXTER LANGLEY.

DR. FRANCIS.—The literature of tuberculosis is of so voluminous a character that it would be useless to give you any special references. If you could spend an hour or two in a good medical library, you would obtain a far better and more suggestive idea of the appropriate volumes for your purpose than we could give you without further details of your particular requirements.

PROFESSIONAL MEN IN AUSTRALIA.

WE are often asked our opinion by correspondents anxious to try their fortune in the antipodes. For these the following information, supplied us by the New South Wales Government Agency, will be of interest: "It can never be too strongly insisted upon that professional men, as a rule, cannot get on so well in Australia as in Europe. Members of the legal profession are numerous in New South Wales, and it is necessary to success that they should have some knowledge of the land system of the Colony. For hard-working medical men, content to bide their time, there are plenty of openings in the country districts, and surgeons accustomed to practice in the mining or rural districts would have no difficulty in forming a connection. Schoolmasters possessing the requisite qualifications can readily obtain employment under the Department of Public Instruction, but there are comparatively few chances for those accustomed only to the work of classical education."

DR. MURPHY.—Surgical ulcers, that prove intractable to ordinary forms of treatment have been cured by the application of a strong solution of chromic acid to them; this mode of treatment was suggested by Mr. H. T. Butlin, F.R.C.S., who got good results from it in several obstinate cases.

B. O. U.—The clinical history of the case is very suggestive of lupus. Unless you are quite convinced it is not an instance of this disease, it might be desirable to proceed on the supposition that it is. Has a microscopic examination of the morbid growth been made?

MR. TRUEMAN.—We are much obliged for the offer your letter contains. At present, however, we have no need for such a representative; but should occasion arise we shall be glad to claim your services.

DR. COLBURN.—The subject has frequently been treated, and always with special reference to the points you insist upon.

MR. E. C. B. (Stafford).—We can only hope, for your sake, the result will equal your enthusiasm.

DR. JOHN MOORE (Belfast).—Your letter, with editorial reply, was crowded out at press; it will appear in our next.

DR. A. J. BLAIR.—Case received; will appear in an early number.

EXAMINERSHIPS IN THE ROYAL COLLEGE OF SURGEONS, IRELAND.

To the Editor of the MEDICAL PRESS AND CIRCULAR.

SIR,—I would be glad to know whether it is not a fact that Fellows of the College are precluded by by-law or resolution of Council from holding Examinerships for more than seven years consecutively.

Yours, &c.

April 19, 1884.

JUSTICE.

DR. MARTIN (Sheffield).—Thanks; the paper has not been forgotten: it has simply been delayed for want of space, which we hope to supply in a week or two.

MR. FOSTER (Bradford).—We have no knowledge of such a publication. Try the German houses in London: Messrs. Trübner, Williams and Norgate, or Asher and Co.

DR. R. M. (Frankfort).—We have handed your letter of inquiry to our publisher, who will reply to you fully.

Meetings of the Societies.

WEDNESDAY, APRIL 23RD.

HUNTERIAN SOCIETY.—At 8 p.m., Dr. Hughlings-Jackson, On a Case of Charcot's Joint-disease in Locomotor Ataxy.—Dr. Fletcher Beach, On Atrophy of the Brain.

HOSPITALS ASSOCIATION.—At 8 p.m. (in the rooms of the Medical Society of London), Papers by Dr. Bristowe, F.R.S., and Miss Lückes, On Hospitals as Training Schools for Nurses.

THURSDAY, APRIL 24TH.

ROYAL INSTITUTION.—At 8 p.m., Professor Dewar, On Flame, &c.

FRIDAY, APRIL 25TH.

CLINICAL SOCIETY OF LONDON.—At 8.30 p.m. (Agenda paper not yet to hand).

ACADEMY OF MEDICINE IN IRELAND (Obstetrical Section).—Exhibitions: Dr. Macan, Vesical Calculus from a Patient with Vesico-Vaginal Fistula.—Dr. Neville (for Dr. H. M. Jones), New Instrument for Vaginal Irrigation. Papers: Dr. Macan, Report of the Rotunda Hospital for Twelve Months.—Dr. Neville, On the Prophylaxis of Puerperal Fever.—Dr. Purfoy, On Secondary Hemorrhage.

SOCIETY FOR THE STUDY OF INEBRIETY.—At 8.30 p.m. (in the rooms of the Medical Society of London), Inaugural Address by the President, Dr. Norman Kerr.

TUESDAY, APRIL 29TH.

ROYAL INSTITUTION.—At 8 p.m., Dr. Klein, Nerve and Muscle.

Vacancies.

Birmingham General Hospital.—Resident Surgical Officer and Resident Registrar and Pathologist. Salary attached to the former, £130 per annum, with board and residence; and to the latter, £100 per annum, with board and residence. Applications to the House Governor by April 26.

Chatham, St. Bartholomew's Hospital.—Assistant House Surgeon. Salary, £100, with board, &c. Endorsed applications to be sent in by May 1.

Coombe Hospital, Dublin.—Assistant Master. Applications to Master, or at Coombe Hospital.

Cheshire County Asylum, Macclesfield.—Medical Superintendent. Salary, £500, with furnished house, &c. Applications to Mr. A. C. Procter by May 3.

Royal London Ophthalmic Hospital.—Clinical Assistants will be appointed for one year from May 1. Applications to the Secretary before April 28. (See advt.)

Royal College of Surgeons, England.—Conservator of the Museum. Salary, £500, with residence. Applications to the Secretary of the College by May 3. (See advt.)

Whitechapel Union, London.—Infirmary Medical Officer. Salary, £150, with furnished apartments, &c. Applications to the Clerk of the Union on or before April 28.

Appointments.

ASHMEAD, G., L.R.C.P. Ed., L.R.C.S. Ed., Medical Officer for the Kingwinford No. 4 District of the Stourbridge Union.

COLL, A., Medical Officer to Knoeknolower Dispensary, Belmullet Union.

DONALD, A., M.B. C.M. Ed., M.R.C.S., House Surgeon to the Edinburgh Royal Maternity Hospital.

DRUITT, L., M.D., C.M. Ed., L.R.C.P. Ed., Medical Officer for the South Lambeth District.

FRASER, T. A., M.B., C.M. Ed., M.R.C.S., House Surgeon to the Edinburgh Royal Maternity Hospital.

HUNT, G. A., L.R.C.P. Ed., M.R.C.S., Medical Officer for the South Hornsey District.

MCLAUCHLAN, T. G., M.B., C.M. Ed., Medical Officer to the Hales Owen District of the Stourbridge Union.

TAYLOR, R. W. G., B.A., M.B., M.Ch. T. C. D., Medical Officer of Health to the Framham District of the Mitford and Launditch Union, Norfolk.

Births.

AUCHINCLOSS.—April 18, at 35 York Street, Dublin, the wife of Hugh A. Auchincloss, F.R.C.S.I., of a daughter.

KYLE.—April 18, at Measham, Derbyshire, the wife of T. W. Kyle, M.D., of a daughter.

PURVES.—April 17, at 20 Stratford Place, London, W., the wife of W. Laidlaw Purves, M.D., of a daughter.

Deaths.

BOND.—April 7, at Teignmouth, South Devon, Harman Reed Bond, Surgeon-Major (retired), Bengal Army, aged 72.

HENTSON.—April 12, at St. George's Cross, Southwark, S.E., William Hentsch, Resident Medical Officer of the Royal South London Dispensary, aged 75.

JOSEPH.—April 8, at Oaklands, Builth, South Wales, Thomas Morgan Joseph, M.R.C.S., L.R.C.P., aged 40.

PARSONS.—April 15, at his residence, Ivanhoe House, Newhaven, Sussex, Charles Parsons, M.D., L.R.C.S.I.

The Medical Press and Circular.

ON

METASTATIC PHLEGMON OF THE HAND.

By PROFESSOR THEODOR BILLROTH, Vienna.

THE patient was confined four weeks ago, and suffered from some febrile symptoms in childhood; there was, therefore, something about the genital organs not quite in order, but the symptoms never became of marked importance. Probably there was some parametritis present. A fortnight later an inflammation of the carpal bones came on. This must not be taken as accidental; we must rather look upon it as a metastasis of the original inflammation in the parametrium. With the ostitis of the carpal bones was associated suppuration of the sheath of the tendons; later on the inflammation progressed upwards, in part in the subcutaneous cellular tissue, and in part underneath the muscles. It frequently happens in puerperia that a comparatively small focus of inflammation brings in its train very grave conditions, such even as threaten life itself. Upon the whole, we may say that these metastases, when, as in this case, they find their way towards external parts, to the subcutaneous cellular tissue, or a little deeper, generally make their way out, whilst those that are transported internally bring about a lethal termination. The parametritis has here apparently died away, but the inflammatory process still exists; it is not easy to get rid of, as it lies deep, not only in the subcutaneous cellular tissue, but in the joint, in the bones, and in the sheaths of the tendons. The causes from which suppurations of the subcutaneous connective tissue take their origin are most frequently injuries, and especially crushes; but purulent inflammations do make their appearance, which apparently arise without the slightest external injury, and in which the question as to their cause cannot be answered. In some of the suppurations of this kind the spontaneous origin is only apparent—not real—as in most cases they originate in previously exist-

ing centres of inflammation, only the primary focus is not known, or quite overlooked. It is frequently the case that quite insignificant irritations are the cause of such conditions, and this is especially so in phlegmons that form at the tip of the fingers, in panaritias, and in those that form on the foot and especially around the bones.

Panaritias are especially frequent in cooks, and in individuals who have to handle substances of doubtful cleanliness; in cooks the epidermis is swollen, easily permeable to infective material, which may be furnished by meat which is not used fresh, but must be kept for some time before being cooked. Phlegmons of the foot came on in people who go about barefooted, or from chafing by hard boots, or from a nail penetrating the foot—such sores forming places of entrance for the infective material.

All these processes, when they have reached a certain degree of intensity, become more or less quickly and widely diffused, and act more or less upon the system generally. This is dependant on the intensity of the poison which the micrococci either introduce with themselves, or which is first generated by their growth, for the mechanical entrance of a foreign body alone would not be sufficient to lead to such consequences. Such inflammations only are called metastatic as make their appearance whilst another inflammation is in progress, and which, as observation teaches, has a certain relation to the preceding inflammation. If a person either spontaneously, or after an injury, has a phlegmon on the arm, and at the same time during its course develops another on the foot, or inflammations in the lungs, we have to do with metastatic processes. The explanation lies in the word itself that a connection exists between the two processes—that the process has shifted itself to a certain extent from the one locality to the other. Our predecessors thought that the first process must cease, and that by the suppression of it the second centre originated. But it is not correct that the first process must cease for the second to originate. According to the present view, we can say that the infective material passes from the primary centre through the

lymphatic channels into the blood, and is deposited—it may be here, it may be there—and after the micrococcus vegetation has once become established, a metastatic inflammation is originated at the spot. Fortunately, a barricade against the further spread of infective material is generally erected in cases where strong inflammatory infiltrations are present. The lymph channels are occluded, and it is characteristic of these inflammations that they are generally enclosed in a very short time; the centre of inflammation becomes encircled and encapsuled; the lymph passages, and the cellular interspaces become blocked up by fibrine; later on new tissue; and the infection cannot pass farther. When such an abscess is opened sufficiently early, the therapeutical results are favourable; when the pus has escaped healing takes place with rapidity. Only when the inflammation passes downwards the mechanical conditions are exceedingly unfavourable, as between the bones many lacunæ exist, in which the pus collects and cannot empty itself; and it is this wherein the great difficulty of healing lies. In the case of our patient, notwithstanding the depth of the centre by means of numerous incisions giving free exit, the process is so far got under control that an anchylosis of the wrist-joint only will result. She has no longer any fever; if she should, however, have rigors, high temperature, and dry tongue, then we should have to consider whether amputation would not be necessary.

We will still go on with the question, "In what way can we explain those inflammations without existing injuries of the skin?" Cannot infective material, diphtheria and decomposition bacteria penetrate the uninjured cuticle, enter and set up inflammations? We must answer with a decided—Yes; and more especially there are diphtheritic poisons that can penetrate into the skin through the hair follicles. But how is inflammation of the sheaths of tendons to be explained, and acute osteomyelitis? It appears to be proved beyond a doubt that the pus from these processes contains micrococci in great numbers, and that suppuration of this kind has its origin from the micrococci, but the pathway of infection is completely unknown—it is problematical whether the immigration of the micrococci takes place through the lungs, or through the intestinal tract or some other way. I have at one time defended the following explanation:—It is scarcely conceivable that the body does not always contain within itself a number of bacteria germs; a healthy organism is, however, proof against the ordinary bacteria of decomposition, or the conditions for their development are not present. The mucous membranes have such a powerful action that the bacteria germs cannot develop on them. If small particles of carbon can be taken up and transported to the axillary glands, why should not the minute micrococci find entrance into the blood? I have, therefore, assumed that a certain number of micrococci are always present within the body, but that in the case of healthy strong individuals they cannot arrive at development. But if the liquid become stagnant at any particular spot, the germs gain the upper hand in the unhealthy locality, and then it is not this diseased centre that is the cause of the inflammatory process, but the micrococci which have here obtained an opportunity to develop. I have prepared a glass with boiling oil and melted paraffin, have then very quickly removed the skin from the extremity of a rabbit, excartulated, thrust the parts into the boiling oil, and thence in a moment into the paraffin. In a short time the flesh was crowded with bacteria. From this I have drawn the conclusion that the bacteria were there before, and that a number of bacteria are present in every animal organism, but that they do not develop for the reason that for development no suitable soil is present.

The experiments upon which I have relied are incomplete conclusions, however, and more recently Meissner, of Göttingen, has succeeded in showing that it is improbable that micrococci exist in the normal living organism. He has succeeded in preparing portions of

the liver and spleen of rabbits, the extremities of frogs, in part in serum, in part dried, in such a manner that they have remained unchanged after the lapse of two or three years. This has been achieved solely by means of the most scrupulous cleanliness in manipulation, and entirely without chemical aid. Unfortunately, the results are not yet published, they are of great importance, for they prove that exceedingly careful exclusion of bacteria germs suffices to prevent decomposition. It is (not) necessary to make use of chemical agents that destroy them. According to this, one must say that it is improbable that the living organism contains bacteria germs, but they gain entrance as agents of disease as in the cases of inflammations of the spinal cord, and of the sheaths of tendons. But in what way the micrococci gain admission in these affections we do not know at present. In quite recent times the question has been raised whether any productive suppuration can arise without the agency of micrococci. Klebs has been of the opinion that when the entrance of micrococci is prevented, as, for example, in the case of gunshot wounds no suppuration will follow; Hueter has also said the same thing. In opposition to these views, work in part from the laboratory of Cohnheim has shown that other material also can produce suppuration—croton oil, for instance, that sets up suppuration under all conditions. The material that excites suppuration must be a chemical agent, a material of very labile equipoise (Gleichgewicht), and it is not clear why this chemical action should not be the property of other substances. It is, indeed, possible that in addition to fermentative agents already known, we shall yet discover a non-living agent capable of initiating fermentative processes.

A Course of Lectures

Delivered at the London Hospital during February, 1884.

By JONATHAN HUTCHINSON, F.R.C.S., F.R.S.,

Emeritus Professor of Clinical Surgery at the London Hospital; Consulting Surgeon to the London Hospital, and to the Royal London Ophthalmic Hospital.

LECTURE VI.—*Concluded from page 372.*

DISEASES OF THE NERVOUS SYSTEM OF SYPHILITIC ORIGIN.

Inflammation of Central Nerve Tracts.—Of this variety of the lesions produced in the nervous system by syphilis, the most striking example is that in which evidence of mischief is afforded by ophthalmoplegia; and under the name *ophthalmoplegia externa* Mr. Hutchinson, some time since, described certain cases in which the external muscles of the eye became the seat of affection, through their innervations. In these instances the eyeball assumes a fixed position, the extent of which varies to greater or less degree according to circumstances; and, as a rule, both organs are usually involved; the paralysis, however is restricted to the motor muscles of the eye. In six or seven cases of this description Mr. Hutchinson removed the affected organ, and the influence of syphilis could be traced in all but one, concerning which only a doubtful history could be obtained pointing to this complication as an originating cause. In those cases, where, as here, many nerves are so affected, the seat of the lesion to which their condition is attributable is most probably situated far back in the central nuclei, an assumption justified by the result of post-mortem examinations, which have demonstrated that injuries in this situation did exist in subjects who had exhibited the particular form of paralysis above mentioned during their lifetime. That which is true of ophthalmoplegia externa, moreover, may fairly be presumed to be true also in respect of other nerve nuclei, so that the information that is obtained respecting it may be extended to an explanation of

almost all forms of paralysis. It must further be said, too, that ophthalmoplegia externa itself occasionally is followed by extension of the injury it implies, and may even be implicated by the existence of locomotor ataxy and other diseases associated with nerve lesions. As showing the influence exercised by syphilis in this class of cases, and the difficulty which may be found in sometimes ascertaining without doubt in what relation it stands to the conditions observed, Mr. Hutchinson narrated a case which had been under his care at the Moorfields Hospital. The patient, a gardener, was admitted on account of paralysis of the sixth nerve, and denied that he had ever suffered from syphilis. He came of a very healthy stock, and was seemingly desirous of stating all that could assist a diagnosis of his ailment, with truthfulness. Notwithstanding his declaration, however, mercury and iodide of potassium were prescribed as medicines; and the case progressed for five or six years, by which time the eye became quite fixed. Next, atrophy of the optic nerve ensued; and later, weakness was manifested in the lower extremities, the assemblage of symptoms necessitating confinement entirely to bed for the last year preceding death, when general paralysis and blindness were present. During this latter period of twelve months Mr. Hutchinson had not had the patient under observation, and, being near his residence, he called, with the object of seeing how the case was progressing; only, however, to find that the patient had died the day before his arrival. It was then discovered that the nerve centres were disorganised by unmistakable inflammatory growths of syphilitic origin. Several of the children had been seen from time to time by Mr. Hutchinson, and in none had he been able to trace any signs whereby the validity of the father's claim to be free from syphilitic infection could be disproved; but a surgeon in practice at Wandsworth, and who numbered among his patients the *eldest* daughter of Mr. Hutchinson's patient, subsequently communicated to Mr. Hutchinson that this girl was the subject of well-marked inherited syphilis, possessing the characteristic notched incisors, and being, as well, affected with interstitial keratitis. Thus, and accidentally, the most certain proof of specific infection was obtained, and in a way which could hardly have been anticipated, but none the less satisfactory when once made clear.

Inflammations of Peripheral Organs.—The eye and the ear are the peripheral sense organs which most frequently become the seats of injury; and in the case of the former the changes that occur are capable of being easily observed: Different parts of the organ become seats of inflammation at varying times; the retina, for instance, may be so affected during the secondary stage of disease, and under the influence of mercury the inflammation may very possibly be found to clear up, leaving the structure so far in a healthy state that the power of vision will be retained. This, however, cannot be regarded as a common termination. Sometimes the retina and choroid are simultaneously, or concurrently, affected; while at others inflammation attacks the choroid alone, giving rise to choroiditis disseminata, or that condition known as tiger-skin choroid. The visible indications observed in these cases possess a value above and beyond that of demonstrating the actual condition of the parts observed, for they become important aids in determining what changes may be anticipated to be in progress in structures altogether removed from view, *e.g.*, the pia mater, and which are subjected to such influences as promote the visible alterations in regions accessible to direct examination.

Inflammation of the optic nerve itself, as a consequence of constitutional syphilis is of well recognised occurrence, and it may be observed sometimes at comparatively early stages of the disease in the secondary period; but the cases possessing well-marked features are those which present later in the course of illness, and nearer the tertiary stage.

It was observed by A. Fournier that not uncommonly in secondary syphilis an anæsthetic condition of the skin could be demonstrated; and Mr. Hutchinson is able to corroborate the truth of the observation. The actual condition, however, is rather one of analgesia than of anæsthesia, and the cases in which it has been noticed have been almost all in women, about whom, moreover, the suspicion of hysteria or of feigned symptoms could not be entertained. Another, and convincing proof of the reality of the symptoms observed in such cases is, that under anti-syphilitic treatment they disappear. Mr. Hutchinson said that he had never seen many examples of this form of affection, and in most the part affected was the posterior surface of the hand. His cases include also many—mostly, however, among men—in whom diminished sensation was present in the lower limb; and the suggestion occurs that they imply an affection of the end organs situated in the skin. The area of distribution followed by the anæsthesia renders it impossible to associate it with that covered by the filaments and branches of any known nerve.

Ophthalmoplegia interna constitutes a paralysis of the internal muscles of the eye, *e.g.*, the iris and ciliary. All these structures are supplied by branches through the ciliary ganglion, and Mr. Hutchinson suggests that this ganglion is the probable seat of degeneration in those cases where the internal or intrinsic muscles of the eye are the only parts of which the function is impaired. It must be remembered, however, that the disease may very possibly originate in the central organs; and it is useful to bear in mind that it often precedes the development of those changes associated under the title *ophthalmoplegia externa*.

Meningeal Inflammations.—These forms of injury may be either of a spreading or diffuse kind, or may assume the shape of gummata. The symptoms induced by these assume a considerable variety, and when large gummata exist the amount of compression set up by them may be of very serious importance. Respecting the diffuse variety of inflammation our knowledge is only limited, and much more information concerning it is a desideratum. Its existence, however, need not be doubted; nor that it may lead to very tangible effects.

Inflammations of Bone.—These injuries in syphilitic subjects have long been fully recognised, and present no difficulty that interferes with their character being fully understood.

Arterial Disease.—The lesions of the arterial system resulting from syphilis form a very important class of diseases, from the existence of which grave dangers to the patient must be apprehended. In syphilitic apoplexy, which occurs in this connection, the exciting cause is always thrombosis, and not rupture of the vessel. The mode of onset of the attack is peculiar, and is generally preceded for one or two days by threatening paralysis, the symptom having its origin in the diminution of the blood current through the affected vessels.

Syphilitic hemiplegia is a tolerably common affection from which recovery generally takes place, but not completely. The power of syphilis to imitate other diseases is of the most extraordinary character, and in this association almost all the systems of the body may be implicated. In the case of the skin there is no known form of disease peculiar to it, which may not find imitation in changes produced by the action of syphilitic poison on the regions correspondingly affected. Thus any part of the structure may be selected as a site, and every variety of rash, hitherto described, may be developed through the action of the poison.

Almost the same sweeping statements might be uttered in respect of the nervous system also, and that, every disease described in books as affections of the nervous system, may find imitation as a result of syphilitic affection. Thus, there is a *syphilitic epilepsy* caused by irritation of the brain through the pressure of gummata, and in this disease exactly the same

symptoms are observed as characterise ordinary attacks of epilepsy. Often, however, the degree of imitation is less absolutely complete.

Respecting locomotor ataxy, Mr. Hutchinson does not consider that all cases of the disease originate through syphilis; but he fully concurs in believing that a large number of syphilitic persons suffer from the disease, the course of which may in them be modified by treatment directed to the specific disease, though they will not result in cure. Ophthalmoplegia, also, is not always of syphilitic origin.

General Paralysis of the Insane has been clearly shown to depend on a spreading inflammation of the pia mater, and such an occurrence may readily take place in subjects affected by syphilis.

Under paraplegia several forms are noticed as being syphilitic in type, and facial paralysis comes under a like heading. Mania is due to acute or sub-acute inflammations of the pia mater, and follows from syphilitic infection; and also a class of vague hysterical and allied affections, often of an aggravated kind. Menière's disease, idiocy of the congenital syphilitic variety, and other diseases which might be mentioned, may one and all be traceable to the action of the virus of syphilis on the constitution, and to subsequent invasion of various organs.

Treatment in all cases of syphilitic disease is of paramount importance, and prognosis is most often of a hopeful nature. Reliance, however, must never be placed in a single remedy only, as demonstrated in a previous lecture; but, whenever occasion seems to call for them, both recognised specifics in treating syphilitic diseases should be called into requisition.

THE COMPARATIVE MORTALITY FROM PHTHISIS IN LONDON AND DUBLIN FOR THE PAST SIX YEARS.

By EDWARD SPENCER, M.A.

THE mortality from phthisis in Dublin having latterly increased, and being apparently over the normal death-rate from that disease, it occurred to me that it would be useful to investigate as far as possible the fatality from this cause in Dublin during the past six years, and compare it with that in London for the same period.

Tables are appended, giving the results for the six years ending 1883; the mortality has been calculated for every 10,000 living and the recorded or estimated increase of population allowed for.

The increase in the mortality in Dublin has been chiefly in the municipal district, the rate in the suburbs having somewhat diminished.

TABLE I.

	City.		Suburbs.		Registration Dist.	
	No. of Deaths.	Rate.	No. of Deaths.	Rate.	No. of Deaths.	Rate.
1878	785	31.9	160	23.2	945	30.1
1879	895	36.5	197	28.4	1,092	34.7
1880	938	38.2	199	28.7	1,137	36.1
1881	916	36.7	235	23.7	1,151	33.0
1882	956	33.2	226	23.0	1,182	33.9
Average ...	898	36.3	203	25.4	1,101	33.5
1883	1,086	42.5	244	24.6	1,330	38.0

It will be seen from Table I. that the death-rate in the city proper has risen from 31.9 per 10,000 in 1878 to 42.5 per 10,000 in 1883 (the average rate for the five years ending 1882 being 36.4); in the suburbs, although the rate for 1883 (24.6) is slightly above that for 1878 (23.2), it is nevertheless lower than the average for the

previous five years (25.2); and in the registration district, which includes both city and suburbs, the rate has increased from 30.1 in 1878 to 38.0 in 1883 (the average for the five years ending 1882 being 33.5).

Comparing the mortality in Dublin and London, it will be found from Table II. that the average rate in Dublin for the past five years is more than 45 per cent. higher than in London, and seems to be steadily increasing, while in London the mortality appears to be slightly diminishing (the rate for 1883 being 22.5, as compared with 22.9, the average for the previous five years).

TABLE II.

Rate of Mortality per 10,000.

	London.	Dublin.
1878	24.8	30.1
1879	24.5	34.7
1880	21.9	36.1
1881	21.7	33.0
1882	21.6	33.9
Average	22.9	33.5
1883	22.5	38.0

The question of the incidence of the mortality has next been considered, and is found both in London and Dublin to have been fairly constant during the six years in question. Investigation, however, on this point has revealed some interesting facts. It will be observed from Table III. that the mortality at the age period 5—20 is much greater in Dublin than in London. In Dublin 18 per cent. of the deaths registered were between the ages 5 and 20, as compared with a percentage of 9.7 at the same age period in London. On the other hand, it seems that there is a considerable excess in the mortality in London at the age period 0—5 (4.3 per cent. of the deaths registered) as compared with Dublin (2.0 per cent. of the deaths registered). This excess is, however, in part accounted for by the fact that the proportion of children living at the ages 0—5 is much greater in London than in Dublin. Taking the population at the two age period (0—5 and 5—20) it is found that in London the average death rate at the period 0—5 is 7.3 as compared with 6.1 in Dublin; while at the age period 5—20 the rate in London is only 7.1 as compared with 20.5 in Dublin.

It will also be seen that in London 14 per cent. of the entire mortality from phthisis, equal to a rate of 7.2 per 10,000, occurs among persons under 20 years of age; but that in Dublin 20 per cent. of the entire mortality, equal to a rate of 16.5 per 10,000, takes place within the same limits of age. Contrariwise, after passing 20 years, it is

TABLE III.

Showing the Percentage of Mortality from Phthisis at the various Age Periods in London and Dublin.

LONDON.						
	0 5	5-20	20-40	40-60	60-	Total.
1878 ...	4.9	9.7	48.3	31.4	5.7	100
1879 ...	4.1	10.2	48.8	31.6	5.3	100
1880 ...	4.1	10.1	49.6	30.8	5.4	100
1881 ...	3.7	9.9	50.0	31.4	5.0	100

This last table seems to show that children in London are born under less favourable conditions than those in Dublin, and succumb more rapidly to phthisis at the ages 0—5; that those who survive make a much harder struggle against the disease than the corresponding class in Dublin; and that, in short, consumptive people in London live much longer than those in Dublin.

On the general question it may be observed that we have an insidious disease making strong way among us, while in London it appears to yield to some influences. What these influences are, and whether consumption is a disease which, as the late Dr. Farr says, "is to a considerable extent under control, gives way to hygienic measures, and has decreased step by step within the past 27 years," are questions for sanitarians, but they are questions which, as far as Dublin is concerned, should be answered as soon as possible.

Clinical Records.

LIVERPOOL FEVER HOSPITAL.

A Case of Empyema, complicating Post-Scarlatinal Nephritis. (a)

By ROBERT S. AITKEN, B.A., M.B., M.Ch. Dub.,
Physician, Netherfield Fever Hospital, Liverpool.

EFFUSION into the pleura as a sequela of scarlatina, whether in consequence of scarlatinal rheumatism (so-called) or ensuing during the course of nephritis, is (as far as personal experience is concerned) of much less frequent occurrence than the analogous condition of the peritoneum, which not uncommonly complicates the latter affection. Of a large number of cases of scarlatina that from time to time have come under the observer's notice, this is the only one of empyema I recollect having met with. I cannot find another amongst my clinical records. The comparative rarity of pus in the pleura under these conditions is the only reason for bringing a case of this description under the notice of the profession. This affection would appear to be of as great, or even greater, rarity in small-pox, as in over one thousand cases of this disease observed during a recent epidemic in this city, I met with but one example of empyema. This occurred in a young female, who succumbed from hectic after a free incision had been made into the chest. *A priori* it may be predicated that when effusion does take place into the large serous cavities in the course of the acute eruptive or specific fevers, there would be reasonable suspicion of such effusion becoming rapidly purulent, and, as a matter of fact, I believe that this is the case, especially when the pleura is so affected. In considering these cases the probable existence of a strumous diathesis must be borne in mind. The boy whose case is about to be related was one of those ill-fed, ill-clothed, badly-housed children, which, too commonly in our great cities, are most likely to become the victims of struma.

I have to thank Mr. Blore, late Resident Medical Officer of Netherfield Fever Hospital for keeping the clinical records, from which the following account is abstracted:—

Pat. M., æt. 10, was admitted to Hospital on Dec. 1st,

(a) Read before the Liverpool Medical Institution.

1882, in the evening. The patient was apparently of the class known as "street Arabs," and consequently an accurate history of his previous condition could not be obtained. However, it was ascertained that a fortnight before admission he was suffering from "lumps under the jaws," and when he came under observation the skin was found to be generally disquamating. He was suffering from urgent and distressing dyspnoea; he could not assume the recumbent position; respirations were 60 in the minute; temp. 99°; pulse 100; and his urine contained a half of albumen and blood. There was slight cough. Feet oedematous, and there was a small amount of fluid in the peritoneum. The entire of the left chest was of resistant, woody dullness from top to bottom, with an absence of tactile vocal fremitus, and only distant breath-sounds were audible. The intercostal spaces were flattened, and the upper ones bulging. Cardiac impulse was situated in the right side of the epigastrium. Mr. Blore, after having confirmed his diagnosis of empyema by the withdrawal of some fluid by a hypodermic syringe, and microscopic examination showing pus cells in abundance, sent for me. The circumstances of the case being as related, and the boy being in imminent danger of dying from suffocation, it was determined to make a free incision into the chest. An attempt to borrow a spray apparatus being fruitless, the operation had to be performed without antiseptic precautions. Accordingly, a point was selected in the seventh interspace, a short distance in front of, and slightly below, the level of the inferior angle of the scapula, as being the most convenient to make the incision, and also as being favourably situated for drainage, as the boy lay on his left side. With some little difficulty, owing to the mobility of the soft parts, and the narrow space between the ribs in children, the pleural cavity was opened into, and purulent fluid began to flow in a full stream. When the flow began to slacken, some air was drawn in with a hissing sound. About 30 ozs. of semi-purulent matter escaped. A drainage-tube formed of a French elastic catheter, with the end cut off, and the sides perforated, was inserted down to the diaphragm, cut flush off with the skin, and retained by a thread passed through it by a needle. A large, soft sponge, wrung out of warm solution of carbolic acid, was placed over the side, covered with waterproof cloth, and the whole held in position by a bandage. It was interesting to notice how, as the intra-thoracic pressure became lessened, the respiration became more placid, and finally, after the operation was completed, settled down to 36 per minute. The patient was much relieved by the operation, and was enabled to lie comfortably down.

Dec. 2nd, 11.30 a.m.—Coughing a little. There was free drainage, the dressings being saturated. Air was entering the upper part of left lung, mingled with moist râles. Percussion note was resonant over anterior superior portion of the side. The heart was now beating in the left side of the epigastrium, instead of in the right, as before the operation. Bowels moved once. Moderate thirst; complaints of hunger. No rigors; no sweating; no fœtor. The pleural cavity was washed out with a solution of carbolic acid (1 in 40), and dressed as before. Pulse in forenoon, 118; in evening, 120. Resp. in forenoon, 36; in evening, 58. Temp. did not rise above 99·4°. He was put on milk diet, and a mixture containing liq. ammon. acet., spts. actis nit., tinct. ferri perch. and tinct. digitalis ordered.

3rd.—At 1.40 a.m. pulse was 100; resp. 36. He was perspiring. The side was dressed again. Ascites somewhat increased. 12 noon—Pulse 96; resp. 36; and temp. inclined to rise. The discharge having come through the dressing, the side was again dressed, this time with carbolicised lint and tow. The discharge was perfectly sweet. No change in condition of lung. Not much distress. At 7 p.m. the thermometer registered 101·6° F. At 11.30 p.m. dressing was again changed.

4th.—Discharge from the right ear. Respiratory sounds were heard all over the left side, mingled with râles. Percussion notes considerably improved. Discharge slight, and quite sweet. Temp. rose to 99·6° at 11 p.m. Urine still contained a considerable quantity of blood, but the albumen had decreased to $\frac{1}{4}$. The next day he was put on two eggs. Temp. rose at 11 p.m. to 101·6°.

6th.—Pulse 126; resp. 60. Temp. did not rise above normal, except at 3 a.m., when it was 99·8°. A peculiar kind of tubular breathing, having a metallic character, was audible in upper part of left chest. Discharge less purulent; no fœtor.

7th.—Pulse 120; resp. 40; temp. 100.2° in the evening. Urine contained blood and $\frac{1}{2}$ of albumen.

8th.—Percussion note over left side still rather dull. Plenty of râles to be heard over the entire chest, but especially over the anterior superior portion of the left side. The tubular respiration having a metallic character had vanished. Heart has not regained its normal position. Complained of pain in "his belly," across the epigastrium, where he placed his hands. Ascites seems to be somewhat less. Pulse—morning 130, evening 138; resp.—morning 40, evening 43. Thermometer indicated 101° in the evening. Urine still contains blood, but the albumen has fallen to $\frac{1}{2}$.

9th.—Very little discharge; cavity washed out with a solution of carbolic acid (1 in 40), and the drainage-tube removed. Pulse 130; resp. 38; temp. ranged between 99° in the morning and 101.2° in the evening.

10th.—Discharge moderate and quite sweet; a number of small pustules around the wound. Respiration and percussion note fairly good over left side, except at the lowest third posteriorly, where there is dulness and a few râles, but not nearly so many as there were a couple of days ago. Respiration and percussion note very good over right side, and hardly any râles. Pulse 130; respiration 30; temp. ranged between 99.2° in the morning, and 100.6° in the evening. Albumen reduced to $\frac{1}{2}$, but still some blood in the urine.

For the next three days the pulse averaged 120; resp. 30, and the temp. on two occasions rose to 100.6° and 100° on the evenings of the 11th and 13th respectively.

14th.—Pulse 120; temp. 99° in the morning, 99.4° in the evening. Percussion elicits a comparatively dull sound all over the left chest. Cardiac impulse in fourth interspace about one inch inside the nipple line. Fair respiratory sounds all over left side of chest. Some râles in the lower part of lung behind, and suspicious gurgling sounds below the left clavicle. During this and the two following days the urine contained about $\frac{1}{2}$ of albumen; still some blood. The temp. rose on the afternoon of Dec. 16th to 100.2° F.

17th.—Rather feeble respiration over the entire left lung, whilst on the right side it was somewhat exaggerated. Percussion note high-pitched in left infra-clavicular region; in other parts of this side there was comparative dulness, probably due to thickening of the pleura. A few moist râles were audible in left supra-spinous region. The temp. for this and the following days ranged between 100° and 101°.

19th.—The urine contained much blood. The temp. ranged between 97.2° at 3 a.m. and 102° at 7 p.m. Yesterday he was ordered grs. 2 of quinine and 5ma. each of tinct. ferri perchl. and tinct. digitalis, every four hours.

21st.—Dulness, tubular breathing, occasional friction rub, and pectorilquy over the left base posteriorly, indicating the existence of some pleuro-pneumonia. High-pitched percussion note and fair respiration, mingled with râles under left clavicle. More or less comparative dulness over other portions of left chest. On right side puerile breathing, with occasional râles. Percussion note clear. Cod-liver oil. During the next four days the temperature assumed deep curves, ranging from normal to 103°; at 3 p.m. on 22nd to 102°; at 3 p.m. on 23rd to 101.4°; and to 101.6° at 3 p.m. on 25th. This hectic type of temperature was coincident with the retention of some pus in the pleura, owing to the gradual closing of the opening. However, it was readily evacuated by the introduction of a director and by irrigation.

25th.—Purulent discharge from opening rather copious. The urine still contained blood and albumen.

28th.—Discharge from opening scanty. Percussion note clearer, and respiratory murmur fairly good all over left side. Some falling in of left chest, with deviation of the spine. Good breath-sounds on right side.

29th.—Discharge somewhat more abundant; does not escape readily. During this and the three preceding days the temp. did not rise above 99.4°, but on the next two days the thermometer registered 102° in the evening, and on Jan. 1st the temp. was 100° at 7 p.m. From this time the boy rapidly convalesced as far as the empyema was concerned; the temp. did not rise above normal, except in the forenoon of Jan 4th, when it was 101.2°. The albumen and blood disappeared from the urine, and he gained flesh.

Jan. 19th.—The patient was discharged, the condition of affairs being as follows:—Comparative dulness over left side as compared with right. Respiration fairly good, except

in the axillary region, where some suspicious gurgling râles (probably the precursors of phthisis) were heard.

Measurements of Chest.—Nipple line: Right side, 14 inches; left side, 12 $\frac{1}{2}$ inches. Xiphoid cartilage: Right side, 13 inches; left side, 12 $\frac{1}{2}$ inches.

Transactions of Societies.

ACADEMY OF MEDICINE IN IRELAND.

MEDICAL SECTION.

A MEETING of the Medical Section was held on Friday evening, March 14, at the College of Physicians, Dr. WILLIAM MOORE, President, in the Chair.

Dr. A. N. MONTGOMERY, hon. sec., read the minutes of the preceding meeting, which were confirmed.

LIVING SPECIMENS.

Dr. M. A. BOYD—A case of congenital cardiac disease, with intra-ventricular communication.

Dr. WALLACE BEATTY—A rare form of skin disease.

SPECIMENS EXHIBITED BY CARD.

Dr. C. J. NIXON—Cirrhosis of the kidney and its effects.

In reply to Dr. WRIGHT,

Dr. BOYD described the case he exhibited as one of congenital communication between the ventricles in a child 10 years old. The child had been delicate from birth, and as an infant had been very near dying. Recognising the case as one of cardiac disease, on examination he found a systolic murmur localised between the nipple of the left breast and the middle of the sternum, on a line with the nipple, extending upwards to the cartilage of the third rib on the left side. Within this boundary the murmur was loudest. There was more or less hypertrophy of both ventricles. The left ventricle acting stronger in its contraction than the right, caused, in his opinion, the hypertrophy of the right, which in this is greatest. There is a possibility of some congenital obstruction at the pulmonic orifice to help to produce this, as the murmur is propagated towards this opening.

A RARE FORM OF SKIN DISEASE.

Dr. WALLACE BEATTY read a paper describing two cases affected with a peculiar form of skin disease, resembling in some of its features urticaria pigmentosa. The patients were two brothers, aged respectively 15 and 12 years. The disease first appeared at the age of 12 in the elder brother's case, and at the age of 11 in the younger. The course of the affection appeared to be as follows:—An itchy spot manifests itself without any appearance of eruption. The patient scratches it. Redness, and sometimes, according to the elder brother's statement, an appearance like tubes is seen. This subsides, and in a few hours a slight raised pimple is observed, pin-head size or a little larger. This soon flattens, enlarges, and becomes dull, brown pigmented, forming a circular spot about $\frac{1}{2}$ -inch in diameter, presenting to the finger passed over it either the feel of normal skin, or of skin rather tougher than normal. This pigmented skin spot is unaltered by pressure. After a little the centre becomes whitish, the pimpling remaining brown, and finally the brown colour disappears, leaving white spots of different sizes, some very small, others large, but the greater number smaller than the brown macules. Some of these white spots are on a level with the surface of the skin and firm to feel, while others present minute depression somewhat thimble, or minute grooves radiating from the centre, appearing like scars. All these varieties, pimples, brown macules, macules with a brown pimpling, and whitish centre and white spots are present on various parts of the body, the front and back of the chest being most affected. A mottled appearance is thus produced, which is specially evident on the back. The abdomen and genitals are spared. The face is only a little affected, and the flexor aspect of the limbs but slightly affected. Dr. Beatty could not developae factitious wheals. There is no reason to suspect syphilitic taint. The disease, while it resembles urticaria pigmentosa in the presence of some itchiness, wheals produced by scratching, and subsequent pigmentary changes, is distinguished from all the cases of that disease formerly described in the following points:—(1) The disease commenced several years after birth. (2) The spots are at first chiefly papular, and rapidly

flatten; they are not, as in most of the cases of urticaria pigmentosa, in the form of vesicles, tubercles, or nodules, and localised infiltrations. (3) The final stage, the formation of white spots, is peculiar.

Dr. WALTER SMITH said there could be no question that the disease described was one of great rarity, and of considerable practical importance, on account of the possibility of confounding it in younger patients with erysipelas, and in the older with stains left by secondary rash. He saw both boys some weeks ago, and was struck by the peculiar features of the disease as described by Dr. Beatty—the trophic changes and the production of soars without any vesication, pustulation, or breach of surface. It was not easy to give the disease a name other than that mentioned by Dr. Beatty—urticaria pigmentosa. Of the ordinary form of urticaria the usual features were suddenness of onset and rapid evanescence. The eruption here began early in life, persisted for months and years, and went through cycles of aggravation and decline, and in these respects presented marked features of contrast with ordinary urticaria. It was a question whether it should be put under the same heading at all. Anyone who looked at the picture of Dr. W. Morant Baker's cases in the Clinical Society's Transactions would say the eruption approximated nearer to Dr. Beatty's case than the illustration in Dr. Tilbury Fox's Atlas. Dr. Beatty had laid stress on the difference observed in his own case as compared with those already recorded. As there had been only nineteen cases recorded, the natural history of the disease, if it had any, was not exhausted, and therefore it was obvious Dr. Beatty might have an opportunity of recording features in the disease hitherto not met with by other observers. As to what could be done for patients suffering from the disease, there was little to be said beyond the fact that they must be content to await the will of the healer of all diseases.

Dr. FINNEY said it was usual to find pigmentation following a great many eruptive diseases. There was a red or blood spot where there had been scratching, and it was quite possible the rash of the itching spot might be pruritis, but there were also spots on the back. The case was a great puzzle, and the chief point of interest was the importance of distinguishing it from the congenital and acquired forms of specific disease.

Dr. BEATTY, in reply, pointed out that the spots developed spontaneously, and that, at all events, it was obvious all of them could not have been produced by artificial scratches.

CASE OF PARALYSIS IN A CHILD.

Dr. MACSWINEY reported the particulars of a case of temporary spinal paralysis in a boy, *æt.* 6, and exhibited the patient, quite recovered. The boy had whooping-cough for three months. After this he was exposed to rain and cold for hours on an outside car, and got an attack of tonsillitis. This was treated with local application of caustic solution, and was cured in a week. About this time, also, he commenced to cut up four permanent molar teeth, which caused much pain. Now it began to be noticed that he was unsteady on his legs in walking. This feebleness of gait increased rapidly, extending upwards through the trunk to the arms. The muscular feebleness became daily worse, and finally, in a very short time, he was universally and completely paralysed. He could not stand, was not able to use his hands to bring food to his mouth, had to be fed, lay in the bed quite helpless, and was lifted out and in as occasion required. All this time his general health was good. He ate and slept well, looked healthy and intelligent, his muscles were not in the least atrophied, his voice was natural, he protruded his tongue in mid-line, his sphincters were unaffected, he had no fever. The electrical contractility of his muscles was unimpaired. The "sole of the foot" reflex was present. The "patellar tendon" reflex could not be demonstrated. Regarding this latter, Dr. MacSwiney found experimentally that it was not manifested in several young boys, and he raised the question, Was it present in such subjects at all? Mobility rapidly returned to the muscles, and in three weeks' time he was as well as ever. The case closely resembled Landry's disease in all important particulars. There was motor paralysis spreading rapidly from below upwards, unaccompanied by fever, not involving sensibility, the bladder or the rectum, without atrophy or change in the electrical excitability of themselves. There were also the salient points in paralysis *acuta ascendens*. As to its etiology, it was not anemia of the antero-lateral columns of the cord from exhaustion consequent on the pertussis. His good condition and health were inconsistent with

this. It was not the result of exposure to cold. This had expended itself in the attack of tonsillitis. It was not due to intestinal worms. Anthelmintics brought none away. It was not chorea paralysis, in which there are clonic spasms, where the paralysis is never universal, and where the general health is always impaired. It was not diphtheria paralysis, because this begins in the soft palate and pharynx, and is incomplete, is denoted by loss of Faradaic contractility, anæsthesia, dysphagia, nasal voice, defective eye accommodation, amaurosis, accompanied with a fatuous, idiotic expression of face. There remained reflex paralysis from dentition. To this Dr. MacSwiney attributed the initiation of the symptoms. He lanced the gums. Coincidentally with this the patient got better, and soon became well. His view of the series of pathological events was—exalted reflex irritability excited by difficult dentition, producing a dynamic lesion of the cord, unaccompanied, he assumed, by any structural alteration, and culminating in this attack of transitory spinal paralysis.

Dr. HENRY KENNEDY considered the extraordinary feature of the paralysis was its short duration. Having seen the case, he regarded it as presenting the appearance of a modification of chorea. No doubt the state of the mouth had a good deal to say to its development. He had seen a good many cases where purging sufficed to cure the disease.

Dr. GUNN having observed the case from the admission of the little sufferer into hospital until he left, said he felt puzzled at first as to the prognosis, because the child was going from bad to worse, and becoming completely paralysed. He would have given an opinion that the case was one of paralysis pure and simple. Dr. MacSwiney had not laid sufficient stress on the choreic symptoms which at first developed. The rapid cure was entirely owing to the removal of the exciting cause, by Dr. MacSwiney having lanced the gums.

Dr. NIXON was chiefly interested in deciding what the case was originally. From the observations at the end of his paper, Dr. MacSwiney would regard the case as one of reflex paralysis, probably tracing the origin of the paralysis to an irritating process going on in the gums. But he was himself disposed to think that, as their knowledge of nervous diseases progressed, the less inclined they would be to attribute traces of paralysis to reflex causes, and the term reflex paralysis would become more and more rare. The occurrence of paralysis from peripheral irritation, such as worms in the intestines, or the irritation going on in the development of teeth, was very unusual. As the result of the investigations of Brown-Séquard, it was shown that in those cases where paralysis occurred from peripheral irritation, what was dealt with was not a reflex process, but an ascending neuritis. In children peripheral irritation connected with the teeth and transmitted to the nervous system would not result in paralysis, but in convulsions; and consequently, he would not regard Dr. MacSwiney's case as one of reflex paralysis. Then what was it? Dr. MacSwiney had given a clear history that at the starting-point of the disease the patient had had sore-throat with a number of white patches on the throat, and he would regard the case as one starting in diphtheria, and the paralysis that ran such a rapid course as diphtheritic paralysis. He did not think there was the special type so well marked as usually in Landry's paralysis. There was a typical case of this affection at present in Dundrum Lunatic Asylum.

The PRESIDENT regarded Dr. MacSwiney's case as of great practical interest. It recalled a case in his own experience, a young girl, *æt.* 15, who had nasal utterance and difficulty of swallowing. She became ataxic. Previously to coming under his care she had suffered from sore-throat. In some respects his case differed from Dr. MacSwiney's. There was albumen in the urine, and recovery, though perfect, was not so rapid. He held with Dr. Nixon, that the sore-throat in Dr. MacSwiney's case was the beginning of the formidable lesion to which he had referred, and had the patient been twenty years older, the paralysis would have been of longer duration.

Dr. MACSWINEY, in reply, said the President's case was no doubt one of true diphtheritic paralysis, but he found it utterly impossible to regard his own as due to diphtheritic affection, and there was absolutely no chorea present in any portion of the history of the case. Chorea was manifested mainly by chronic convulsions, but at no time were such convulsions present. Authorities the most eminent had placed upon record cases in which extremely well-marked ataxic paralysis was referred to dentition. Dr. West had recorded a valuable case of paralysis due to the extrusion of molar teeth. Therefore, in urging that the case was probably due to the reflex irritability or excitability consequent on dentition he was doing

that which appeared to be likely from the history of the case and of similar cases recorded in great numbers.

ETIOLOGY OF CLIMATIC FEVERS IN INDIA.

Dr. S. N. MONTGOMERY, at the request of Surgeon-Major Gore, A.M.D., read, by permission of the Council, a paper on the etiology of the common climatic fevers of the Kumaon Hill Ranges.

The discussion on this paper was postponed till next meeting, owing to the lateness of the hour.

The Section then adjourned.

THE SHEFFIELD MEDICO-CHIRURGICAL SOCIETY.

THURSDAY, MARCH 20TH.

The President, Dr. BANHAM, in the Chair.

TUMOUR IN THE MIDDLE FOSSA OF THE SKULL.

Dr. BANHAM introduced to the Society a patient that he considered was suffering from a tumour in the middle fossa of the skull. He also showed sections under the microscope taken from a case of glioma of the pons varolii, which had been under his care in the Sheffield General Infirmary, the clinical features of which had already been brought under the notice of the Society at an earlier meeting during the life of the patient.

HYSTERECTOMY.

Dr. KEELING related the particulars of a case of hysterectomy in which a large uterine tumour was removed, along with the body of the uterus and its appendages, by abdominal section. The broad ligaments containing large vessels running up into the mass above were tied in two portions with catgut ligature, and the stump of the tumour secured by means of Koeberle's serre-neud in the lower angle of the womb. A smart hæmorrhage which occurred twenty-seven hours after the operation was stayed by tightening the wire ligature. With this exception the patient made an excellent recovery, and at the end of seven weeks was about to leave the hospital.

Dr. WHITE on a

CASE OF TRANSVERSE FRACTURE OF PATELLA.

John G., æt. 46, a labourer, admitted into the hospital under the care of Dr. Keeling on the 20th Oct., 1883. Had a transverse fracture of the left patella produced by muscular violence. There was not very much separation of the fragments. The knee was extended, and a back splint with a foot-piece adjusted; the hip was flexed, and the foot raised about 18 inches. A piece of strapping broad enough to encircle half the limb, was put on the front of the thigh, from its inferior angles two pieces of calico bandage stitched to it passed down over the foot-piece and were drawn firmly downwards so as to counteract the action of the extensor muscles of the thigh. Ligamentous union with $\frac{1}{2}$ of an inch of separation took place. Ten years previously he had fractured the opposite patella. The treatment then adopted seems to have been almost *nil*. The fragments are now 3 inches apart, but the movements of the joint are very good, and the power of the limb almost unimpaired. Points of interest: Fracture of one patella following that of its fellow not unusual; the very useful limb with 3 inches of separation of the fragments.

DOUBLE OVARIOTOMY.

Mr. W. BANHAM related the notes of a case of double ovariectomy which had been successfully performed by Mr. G. Shaw, of Attercliffe, on a woman, æt. 44. The first operation was performed on September 12, 1883, and the second on January 7th, 1884, a period of less than four months having elapsed between the two operations. The right (first removed) cyst was found to be a multilocular one, which had undergone sarcomatous changes. At the time of operation the left ovary was examined and found apparently healthy. When removed later, the left was ascertained to be a cystic sarcoma, and the cyst wall had ruptured before the operation, its contents escaping into the peritoneum. A smart attack of acute peritonitis followed, although the temperature was persistently below 98°4'; the patient was, however, able to leave her bed in less than a month. The disease had since recurred in the uterus.

A QUARTER OF A CENTURY'S SURGERY, ETC.

Mr. ARTHUR JACKSON read a paper entitled "A Quarter of

a Century's Surgery, its lessons, its failures, its disappointments, its prophecies." This will be published *in extenso* in a later number.

LIVERPOOL MEDICAL INSTITUTION.

THE Twelfth Ordinary Meeting of the Session was held on Thursday, March 27th,

DR. GEE, President, in the Chair.

TUBERCULOSIS OF THE URINARY ORGANS.

Dr. RICH showed a specimen of tuberculosis of the urinary organs, taken from a man who died in the Liverpool Royal Infirmary on March 8th. He was a baker by occupation, æt. 19, and was admitted into hospital on February 8th. There was a strong tuberculous history. He had had scarlatina at 4 years, and rheumatic fever at 9. From this time he had enjoyed good health up to twelve months ago, when cough began and then emaciation. He afterwards complained of pain in the lumbar region and tenderness, the urine contained pus and there was frequent micturition. He died twenty-nine days after admission. The lungs on post-mortem examination were found studded with miliary tubercle, but no cavities existed. Both kidneys were the seat of large caseous masses, and the bladder of tuberculous ulcers. The prostate was almost wholly destroyed.

Dr. HYL GREVES showed a liver from

A CASE OF ACUTE YELLOW ATROPHY OF THE LIVER IN A CHILD æt. 1 year, 8 months. Admitted into Children's Infirmary, Mar. 6, 1884. *History*.—Had always been a healthy boy from birth till Christmas last, when he had a slight attack of jaundice from which he recovered in four days. He had no constitutional disturbance. He remained well till the 23rd of February, he then again became jaundiced and seemed feverish, as he continued to get worse he was brought to the Children's Infirmary, and admitted on March 9th. The family history threw no light on the case and was unimportant. There was no other case of illness in the house. *State on Admission*.—He is a well-nourished strongly made child, much jaundiced all over the conjunctiva, other mucous membranes being similarly affected, there were a few subcutaneous ecchymoses on the flanks and abdomen, but no œdema. He seemed fairly well and free from pain, and he took his food well (milk diet). He was, however, very fretful and irritable at times. The liver was distinctly enlarged, the lower margin which was firm and somewhat resistant being clearly felt about 1½ inches beyond the lower margin of the ribs, it did not then seem to cause pain when pressed upon. His bowels were open regularly once or twice daily, the motions being very pale and smelling offensively. He passed urine in fair quantity, it contained bile, but no albumen or leucin or tyrosin throughout the course of the case, though it was carefully looked for. He had no vomiting, nor diarrhoea, his temperature was normal, and, excepting the slight irritability, there were no nervous symptoms. The case was thought to be one of simple catarrhal jaundice and was treated accordingly. He remained in very much the same condition till March 11th, when he became somewhat drowsy and more irritable. In other respects he was no worse. March 15th he was very restless, constantly tossing about in bed and screaming out in evident pain, he lay on his abdomen with his legs drawn up. He had slight convulsive movements also in the right arm. The liver was found to have diminished considerably in size, and the lower margin had lost its previously well defined margin, indeed, it could not be at all clearly defined, there was increased tenderness on pressure, this, in addition to the other symptoms lead us to suspect that the case might be one of acute yellow atrophy. Next day, the breathing was somewhat stertorous, the convulsive movements of the arm continued with occasional intermissions. He cried out when disturbed, but apparently did not recognise anyone. Pupils dilated and acted sluggishly to light. Temperature 100°2° F. On the 17th he was much worse, quite unconscious, breathing stertorous, pulse over 140 and very feeble. His temperature began to rise rapidly, reaching to 104° F. at night. He was strongly convulsed at times both in arms and legs. He vomited yellowish fluid. Passed urine freely. Bowels opened by injection, motions still white. Cold sponging failed to prevent the temperature from rising, and he died on the 18th at 8 a.m., the thermometer having risen to 108°2° F. *Post-mortem Notes*.—

Liver weighed 12½ ozs., less firm than normally, of a dirty yellow ochre colour throughout, all trace of lobulation lost. About ½ an oz. of yellow bile in gall-bladder which flowed freely along bile ducts into duodenum. Slight ecchymoses beneath peritoneal covering of gall-bladder, and another larger one had taken place in the substance of the right supra-renal capsule. No ecchymoses were found elsewhere. On microscopic examination the liver cells were found to be greatly disorganised, a few normal cells were present, all, however, contained irregular masses of bright organic yellow coloured pigment, which also existed free between the cells, many of the latter became almost black when treated with osmic acid, showing the presence of a large amount, no crystals of leucine or tyrosine were found. There was no increase in the connective tissues, and no evidence of catarrh of the bile ducts. The kidneys were pale, considerably enlarged, and extremely fatty, being of a uniform opaque yellow colour. The other organs with the exception of being bile-stained were normal.

Mr. PAUL showed a specimen of

CONGENITAL SARCOMA OF THE KIDNEY.

The growth occurred in a female child, and was first noticed at the age of six months. It grew very rapidly, associated with extreme emaciation, and ended fatally at the age of one year. When admitted, under Dr. W. Williams, one month before death, the tumour was much too large to admit of any question of operation. It sprang from the left lumbar region, and filled almost the whole abdomen. The upper part was cystic, and about a pint of thin brown fluid was drawn off with the aspirator. The lower part was all solid, but so soft as to communicate a sensation of fluctuation. At the post-mortem the tumour weighed six pounds, the rest of the body weighing ten pounds. It had probably commenced in the region of the hilus as normal kidney encapsuled the lower part of the tumour. Its chief vascular supply was the renal artery, enlarged and elongated. On section, the growth was of brain-like consistence and appearance, and externally soft and homogeneous, in older parts rather more dense, and showing tracts of large soft-walled vessels, hæmorrhages, degenerated, but not necrosed, looking patches, and other irregularities of structure. The large cyst at the upper part appeared to have originated from softening of a clot. It had no intra-cystic growth, nor proper cyst wall. Under the microscope the young growth consisted of a vascular embryonic connective tissue, resembling the embryonic subcutaneous tissue of an early embryo, and it very clearly, in the other parts, passed through the various stages of development of cellular tissue, showing an inter-cellular fibrous stroma, and ultimately a perfect areolar tissue, in which were well grown yellow elastic fibres. Mr. Paul said that this specimen strongly supported the advantage of classifying these distinctly congenital growths by themselves. He believed that when carefully examined throughout, they would all be found to be of a complex character, and resembling the ultimate evolution of that portion of the protovertebral somite from which they took their origin. To place a tumour containing (accidentally) striated muscular fibres in a class by itself, and to regard the above specimen as a variety of round celled sarcoma, was to neglect what was perhaps the clearest indication that we had in the whole series of tumours for a sound basis of classification.

Mr. C. G. LEE then read a note on the "Vitreous," which will appear in our next.

Dr. CATON read a paper founded on

NOTES OF EIGHTY-FOUR CASES OF ACUTE PNEUMONIA AND PLEURO-PNEUMONIA, WITH SOME REMARKS ON SEPTIC PNEUMONIA.

He remarked at the outset that pneumonia varied in type. It was generally sporadic and mild, but at times it was of a malignant type. It was almost universally regarded as non-infectious. He compared it to pleuro-pneumonia in cattle, which had long been known as a sporadic disease, but which became epizootic in 1842. He alluded to some of the numerous epidemics mentioned in medical history, that of Belgium in the 16th century, those of Chester, Christiania, and in later times to the Mediterranean epidemic of 1860, in which the fleet was attacked. The sick were landed at Malta, and communicated the disease to the inmates of the hospital. Still later was the epidemic in Ireland in 1863, in which the mortality was excessive, that in Hanover in 1878, in which pericarditis occurred in one-fourth of the cases, and mening-

itis in one-ninth, whilst fatty degeneration of the heart and nephritis were observed. The discovery of the micrococcus of Friedländer was interesting as possibly explaining the occasional epidemic character of the disease. A description of the micrococcus and of experiments made with it on animals was given, the micrococcus itself being shown through the kindness of Dr. Dreschfeld, of Manchester. The 84 cases tabulated included acute pneumonia and pleuro-pneumonia, catarrhal pneumonia was, as a rule, excluded. The deaths were 29 in number, the rate of mortality was high, but this was partly owing to the class of patients treated at the Northern Hospital, in which all the cases were observed. These were generally sailors and dock labourers, many of whom were intemperate. As an illustration, he mentioned the case of one man who acknowledged that he was in the habit of drinking 3 quarts of rum daily. There was also a large number (12) of drowning cases. The disease had shown itself of a malignant form at times. Thus in 1879 there were 13 cases of pleuro-pneumonia, with 7 deaths. In 1880 the type was mild, but towards the end of the year, and through the year 1881, 17 cases occurred, 10 of them being cases of pleuro-pneumonia, and out of the 17 no less than 13 died. In the beginning of 1882 the pleuro-pneumonia disappeared, and since then only 2 deaths had occurred. He considered that his views as to the occasional malignancy of type were confirmed by the hospital statistics and medical officers' returns for the period. In 1876 the deaths from pneumonia in hospital and in the city generally were respectively 63 and 597; in 1877, 79 and 593; in 1878, 118 and 670; in 1879, 134 and 803; in 1880, no returns; in 1881, 172 and 930; and in 1882, 135 and 850. On inquiring into the locality of the city that furnished the greater number of cases, he found that there were two principal centres that had furnished a considerable proportion of the cases. The treatment had been on the same line throughout. At the commencement of the disease large jacket poultices were applied, first of mustard and then of linseed, and changed every four hours. Great care was taken to avoid exposure of the patient's body to cold and draughts. At first the diet was of milk, and a more nutritious diet was given as the patient was able to benefit by it. Brandy was given if the heart sounds became feeble. The drugs administered were carbonate of ammonia, 5 grains every four hours; with senega or sweet spirits of nitre. If the cough was irritating, opium was given in small doses; aconite if the pulse was full and bounding; if resolution was slow, counter irritants (croton oil liniment) were applied.

Dr. CAMERON wished to make some remarks on the pathology of the disease. As regarded the micro-organisms found in the disease, he did not think the evidence forthcoming was strong enough to show the relations of cause and effect between the organisms in question and the disease. He could not recall a single instance in which the disease showed an infectious character. He had seen epidemic pneumonia but not infectious pneumonia. Every now and then an epidemic type prevailed, in which the cases occurring were of a much lower type. The reader of the paper had made no mention of the influence of the seasons. The mortality depended on so many causes—age, the time at which the cases came under treatment, if in the first stage they recovered, but if in the third stage they did not. The intemperate habit of patients had a good deal to do in determining the issue. Those cases were very fatal that resulted from falling into the water in a state of intoxication.

On the motion of Dr. DICKINSON the discussion was adjourned to the next meeting.

The Royal Free Hospital, London.—The annual dinner in support of this institution was held at Willis's Rooms, on Wednesday last, under the presidency of the Lord Mayor. After the usual loyal toasts his lordship made an earnest appeal to the company on behalf of the Hospital, which, since its foundation in 1828 up to the end of last year, had received no fewer than 1,794,515 patients within its walls. The number of in-patients admitted during the past year was 1,772, being the largest number ever received in the like period; whilst the number of out-patients during the year was 21,142. The total ordinary expenditure for the year amounted to £10,600 odd. In reply to the toast of "The Medical Staff" Mr. Gant, as the Senior, was called on to reply, after which the Secretary announced donations and subscriptions for the evening to the amount of about £1,600.

France.

[FROM OUR SPECIAL CORRESPONDENT.]

THE LOCOMOBILITY OF THE BRAIN.—At the Académie de Médecine M. Bécларd opposed the opinion pronounced by M. Luys in a preceding *séance* on the locomobility of the brain, under certain circumstances and positions. He thought that the word "movement" was badly chosen to represent what passes in the cranium, he would prefer "commotion" or a change in the volume of the cerebral mass which, after all, was very limited, and to be explained by the number of vessels it contained. For him, he could not accept the idea of total displacements as entertained by M. Luys, for there did not exist in the cranial cavity any space that was not occupied either by the brain itself, the venous plexus or the cephalo-rachidian liquid. M. Luys, in replying, maintained what he had already advanced, and was followed by M. Jules Guérin and M. Collin, who were both in favour of the theory of cerebral displacement under the conditions already mentioned. M. Dechambre drew the attention of the meeting to a case of chromodrosis or coloured perspiration. It was observed in a young woman, æt. 28, who, four days after delivery noticed bluish stains on her neck, back, chest, and abdomen. Four months afterwards these stains were of three colours, blue, green and yellow. Her linen was deeply stained, but the colouring matter was easily dissolved in hot water. M. Collin thought that the phenomenon was due in some way to the bile which contained a yellow matter easily converted into blue under the influences of certain acids.

THE QUACK ZOUAVE JACOB.—A celebrity of no small renown, especially in Parisian circles, has just appeared in a rather ignominious position before the police magistrate and heard himself condemned to six days' imprisonment and a fine for illegally practising medicine. The hero, who is popularly known as Jacob, the Zouave, was, in times gone by, a simple soldier in a regiment of Zouaves doing duty in the garden of France, known as Algeria. Was it there that he acquired the power of mesmerising, fascinating, or to speak vulgarly of throwing dust in the eyes of his patients, I know not, but in any case as soon as his service was finished in the colony, he returned to Paris, where, in no less a quarter than the Champs Elysée he commenced to practice his "art." The French people are not a whit behind ourselves in their admiration for all that is mysterious and absurd, and soon the "Cabinet" of our friend Jacob was invaded by a crowd of maimed, half blind, deaf and dumb, with a good mixture of all that was hysterical and hypochondriacal, and I am ashamed to relate, that amongst the latter might have been found persons of very high and honourable positions; a general or two not disdaining to consult the celebrated Zouave. As mystery was the *sine quâ non* in the success of the business Jacob did not fail to envelope all his movements and tactics in that convenient shroud. He presented himself before his patients wrapped in a cloak of oriental design, and walking with majestic step up and down before the *malades*—they were all seated in a row—he made certain passes in front of each patient, and by these outward and visible signs an invisible and magnetic power was pretended to be communicated to the patient, which, of course, was to effect a radical cure. He never asked for money knowing that it would have been illegal, but he sold his own portrait to each patient, so that at the end of his day's work he often made £10 or more. For some reason he left the aristocratic quarter of the

Champs Elysée for the democratic neighbourhood of the famous Rue de la Roquette, and there a "patient" of his assured me, the police had to be told off specially to keep the entry to his residence, so great was the crowd which flocked to consult him. My informant, who was suffering from locomotor ataxy, went to the Zouave to prove his powers of healing, and offered him a good round sum if he would promise to cure him, the "doctor" got into a rage at the idea of doubting his capacities, and remarking that he was grievously wanting in what he considered the most essential quality, faith, he bade him begone! When his game was fully played out he disappeared from the scene and for some years no more was heard of him. Probably he was quietly enjoying the proceeds of his work. Lately he installed himself in the Avenue de Clichy, and, although he had lost most of his former renown, he had yet been able to dupe many of those whose admiration for absurdities has no equal. It is highly probable that the prosecution on the part of the authorities will be regarded as *persecution* by the over-confiding public, and consequently the popularity of Jacob, the Zouave, will be in no small measure increased.

DR. KOCH'S SEVENTH CHOLERA REPORT.

THIS report issued by Dr. Koch from Calcutta, under date of April 4th, is of more than usual interest. After describing the water tanks and their surroundings, and the quality of the contained water, and mentioning the fact that medical men practising in India have often observed localised epidemics of cholera in the immediate vicinity of such tanks, at periods when the disease was not unusually rampant in localities more remote, he goes on to say that he has long had a desire to be informed of such an outbreak in the immediate neighbourhood of a tank. At last (the week before the date of the report), such an epidemic was reported to him in one of the suburbs of Calcutta, in which the cases of the disease were limited to a collection of some hundreds of huts in the immediate neighbourhood of a tank. In a short time seventeen persons died of cholera in this locality, whilst the disease was not prevalent in places remote from this centre. The same spot was repeatedly visited by cholera last year. The Commission at once began its investigations, and it was ascertained that the tank was used by the inhabitants for bathing, washing, and drinking, and that the clothes of the first person that died of cholera were washed in it. Samples of water were then taken from various parts of the tank, and at various times, and were examined by the aid of nutrient gelatine cultivation with the result that in the first samples a tolerably large number of cholera bacilli were discovered, of the later samples that were taken at the close of the epidemic, only one contained cholera bacilli, and this was taken from a very foul part of the tank. When it is borne in mind that so many kinds of water have been examined for cholera bacilli without result, and that they have at last been found in a tank the centre of a cholera epidemic, "this result" he says, "must be looked upon as one of great importance. It is certain that the water in the tank was infected by cholera linen, which according to earlier observations generally contains cholera bacilli in great numbers; it is further ascertained that the inhabitants used the water for domestic and especially drinking purposes. Thus we have here to a certain extent an accidental

experiment on man, which takes the place of the omitted experiments on animals in this instance, and which can be taken as a further confirmation of the assumption that the cholera bacilli are really the causes of the disease."

He then goes on to say that a total of forty-two cholera bodies have been examined and twenty-eight patients, and that the later investigations have afforded nothing new, but that they have throughout confirmed the earlier observations.

The effects of various disinfectants have been studied. Attempts to discover a permanent or resisting form of bacillus have so far failed. "The only possibility," he says, "of keeping the cholera bacilli capable of development, consists in preventing their drying up. In fluids they remain for weeks viable, and everything appears to go to prove that it is only in a moist state that they can be transported and enter the system in an active condition."

No mention, whatever, is made of the successful inoculation of any animal with cholera bacilli by any other investigator.

Owing to the hot season now coming on, and the consequent impossibility of carrying on laboratory work from the great heat, the labours of the Commission will cease for the present.

THE SOCIETY FOR THE CURE AND STUDY OF INEBRIETY.

ON Friday last a new society, having for its object the cure and study of inebriety, was inaugurated at the rooms of the Medical Society of London; and the occasion was signalled by the delivery of an opening address from Dr. Norman Kerr, the President of the Association. Previously to the meeting, a luncheon was served in the large room in which the meetings of the Medical Society are held, and among the hundred and thirty guests attending were a large number of well-known members of the medical profession, including Sir Spencer Wells, Dr. W. B. Carpenter, Dr. Farquharson, M.P., Dr. Hare, Dr. Danford Thomas, Surgeon-General Francis, Surgeon-Major Evatt, &c., &c. Following the luncheon, speeches were delivered in proposing and responding to various toasts, by Lord Shaftesbury, Sir Lyon Playfair, Dr. Kerr, Lord Claude Hamilton, &c., and all the speakers concurred in approving the objects with which the Society had been founded. These were further dwelt upon at greater length by the President, Dr. Kerr, whose address was devoted to recapitulating the conditions under which inebriety exists in this country, and the possible methods for advancing measures for its cure among those suffering under the disease which creates the passion for drink. As to whether any need for such a society can be said to have arisen, especially since the number of medical societies, all more or less supposed to deal with inebriety as part of their work, Dr. Kerr is emphatically of opinion that no mistake on this point is possible; and he believes and insists that a large and beneficent work lies ready to be performed in this direction by such as will bring earnestness and intelligence to assist in prosecuting it. To some extent he explained the nature of drunkenness, regarding it as the outcome of natural law, and drew the distinction between sin, vice, crime, and disease in this connection, the genesis of inebriety forming a special subject of the address. Throughout it was of a nature to appeal to the sympathies of everyone who possesses a desire to lessen as much as possible the vast evils arising from intemperance in our midst; and though evidently designed as an appeal to non-professional hearers, it did not fail also to impress

those medical men who were present as a forcible and eloquent denunciation of drink indulgence, and as an argumentative apology for the creation of a society with the objects described.

Of the prospects before the Association thus floated into existence it would be premature as yet to speak. A good many members will doubtless enrol themselves at first; but inasmuch as solidity of work done rather than numerical magnitude of meetings, must be the test by which it will be tried, there cannot yet be any just criterion of its future success. Such a society may do a very considerable amount of useful, though humble, work if it will consent to occupy the humble position of a handmaid as regards its greater cousins; and there is good reason for assuming that such a position will be not refused by it. Tending to a common end with kindred temperance societies also, its addition to their forces will strengthen the impression made on the national sin of drunkenness; and in every way the new Association is a welcome one.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, APRIL 30, 1884.

THE FUTURE OF THE ROYAL COLLEGE OF SURGEONS OF ENGLAND.—IV.

THERE is an obvious method of determining whom among the members of the Council are at any time most qualified to assume the presidential functions, but which, in mere suggestion, will doubtless be regarded as ultra revolutionary. We refer to the plan of publishing accurate and detailed reports of the periodical meetings of the Council, and of the part taken therein by

individual members of the body. There is really no reason why such reports should be of the meagre nature of those submitted under official sanction at the present time. These afford no evidence of capacity or incapacity for administration on the part of separate councillors, and hence, too, they are useless as a means of aiding the choice of electors under the popular *régime* that will eventually be adopted at the College. It should, therefore, be insisted on that a public record of its history in this connection shall be made part and parcel of imminent reform, and if any sort of inducement beyond the justice and reasonableness of the request is required to commend its adoption, there is one argument which should prove irresistible to ambitious present and future councillors. As it is, these are debarred from enforcing on general notice the great talents they may possess for official life; and are dependent on the chances of permanent tenure of their posts for the reward to which, in secret at least, the most junior of them look forward. In the character of senators deliberating with the knowledge that their speeches will be immediately criticised by the whole body of their possible constituents, renewed stimulus will be given to incite them to acquire a distinguished position among their *confrères*; and not only this, but more permanent and material advantages may also accrue to them from such publicity. The acme of social success, the desiderated baronetcy, will be brought much more nearly within reach; and the life of a councillor will be, under the conditions sketched out, a perpetual struggle, under vastly improved auspices, for the attainment of that which every surgeon figures in his own mind as the goal of his strivings.

But there is another, and possibly a higher ground for the claim we have advanced on behalf of the College as a whole. The actions of the Council are of the greatest interest to those whom its decisions and discussions directly affect, and no kind of excuse can be offered for withholding from the latter immediate and complete accounts of the proceedings taken ostensibly with a view to guarding their concerns. As matters stand at present the Fellows and Members are subjected to indignities which might appropriately be named by a harsher term, in being served with a bare statement of what has been done, in place of a full report of how, and why, and by whom, proposals affecting them have been brought forward. Only under a system the like of which no other similar institution in the world will tolerate, is it possible that the faults complained of could be allowed to exist; and that no voluntary effort from within has ever been made to terminate them is an unanswerable reason why they should be speedily and for ever made impossible of occurrence again.

Among the numerous letters we have received in relation to these articles, a good many ask the question, How in the future is it proposed to differentiate between Fellows and Members as respecting the privileges each class shall specially enjoy? As regards Fellows, it has already been declared by the meeting convened at the College, that to them alone shall be entrusted the election of President; but that they shall, in common with the general body of Members, assemble in annual

meeting to receive the Council's report, and confirm or reject, as may be, the suggestions of that body. To this it seems desirable to add that the election of the Council itself should be confided to the Fellows alone; and thought at first such a limitation seems unjust, yet a little consideration removes the feeling. The attainment of the Fellowship of the College is sought by those who, whether already members or not, aim at a surgical distinction above and beyond that which is a licence to practise merely; and while freely admitting the claim of holders of the latter to share in their own government, it seems clear that the welfare of the institution and its priceless treasures are even more nearly a concern to those who have sacrificed much in time and money to obtain the senior title. Moreover, it always remains open to Members to qualify for participation in the full privileges of Fellows, by taking steps to rank among their numbers; and the injustice, therefore, in withholding from them a power to elect Council and President, is less real than seeming. But were this not the case, there is one other difficulty which is of a practical kind, and is insuperable, to prevent the conferring of this privilege on Members as well as Fellows, that, viz., of recording the votes. It would be manifestly unfair to the majority of the electorate, who by reason of professional engagements could not personally attend even an annual meeting, to refuse them the right of voting by proxy. The labour involved in distributing and collecting some eighteen thousand or more of these documents could not possibly be performed satisfactorily; whereas, if the numbers are reduced within the limits that include Fellows only, the task, though still of great magnitude, becomes at least of possible performance.

We have now to describe the means whereby the objects aimed at may be secured. It has already been said that the smallest amount of sympathy is to be expected from the Council now in office, the majority of its members being averse to admitting Fellows and Members to any share in the government of the College. Consequently it is useless to think of appealing for assistance to constituted authority, and trust must be had rather to those who take a broader view of the question at issue, and will consent to go to the Council under a pledge to advocate the claims formulated by the body of the College. But a few weeks intervene between this and the time when a fresh election to the Council will take place, and this interval should be utilised to find eligible candidates with views in consonance with the spirit of reform. The widespread desire for changes rendered necessary by the progress of events will render it an easy matter to find gentlemen in every way competent to obtain the suffrages of a sufficiently strong electorate to ensure their triumphant return; and in order to economise time it may be well to remember that any answer to the resolutions of the meeting of March 24 has been deferred by the Council till the end of May.

Recruited each year by a contingent of Fellows determined to carry out the unanimous wishes of a representative meeting of the College, the Council will in time become itself an agent in procuring its own reform, and in fulfilling the scheme for abolishing an illiberal and

antiquated oligarchical régime. Meanwhile the formation of a permanent association for reforming abuses, permanent, that is, until its end is achieved, is a first necessity of the moment; and no time is like the immediate present for its organisation.

THE INFLUENCE OF POLITICAL MOVEMENTS ON THE CHARACTER OF DELIRIUM.

IN his lecture at the Salpêtrière on the 23rd of March, 1884, referred to by our French correspondent April 16th, M. Legrand du Saulle discussed the influence of political movements or crises on the nature of delirium, illustrating his observations by the special intellectual and physical anomalies observed in infants born during the siege of Paris. He demonstrated that political and social outbursts influence in this regard only individuals predisposed to mental alienation. There was not, for instance, any increase in the number of lunatics, or cases of mental aberrations during the troubled period extending from 1847 to 1854, and the same holds good as to the period from 1870 to 1871. According to Legrand du Saulle it is rather commercial speculations and sudden reverses of social position which beget mental alienation. In estimating the relative frequency of mental alienation it was pointed out that the increasing vigilance of the authorities has brought to light, and thus considerably influences statistics, a large number of cases of mental alienation, for example, of imbecility, epilepsy, and senile dementia, which formerly remained ignored throughout the country. "This is a fact which falls to be discounted in estimating the relative frequency of mental alienation at the present time. If the political revolutions of 1870-71 have at all influenced the mental state, it is especially because they have modified the conditions of existence. Hence it was that after the declaration of war, when a large number of young men were called to the army, there existed a large number of cases of sub-acute alcoholism, in consequence of the excesses committed under the influence of pending departure to the scene of action. With the approach of the enemy of investiture the suburban population took refuge in Paris; and under the condition of constant agony and anxiety, insufficient nourishment, and bad hygienic conditions, furnished a large number of examples of melancholic delirium. Under the influence of the changed conditions of existence necessitated by the defence other troubles are seen to originate. The men passing their time at the fortifications became addicted to alcoholic excesses, and a great number of them were affected with sub-acute alcoholism; the females insufficiently fed became the victims of psychical troubles due to inanition, such as hallucinations, melancholic delirium, &c. Meantime pure madness seemed on the decrease, the "inventors" alone appeared to multiply. During the period of the bombardment the people of Montrouge demoralised sought refuge in other quarters of Paris, of these a great number were affected with *panophobia*, and of perplexing melancholia. A certain number of the females presented, without any period of incubation, phenomena of melancholia with stupor, of which, after

being cured, they were able to give a succinct account. During all that period the epileptics at the "Aunexé" of the Salpêtrière suffered from no increased number of attacks. In short but one category of the insane seems to have been notably augmented, viz., the "inventors," who became markedly more numerous up to the period of the Commune. In the presence of evidence on the hereditary and personal antecedents of persons at that time affected with psychical aberrations the existence of *obsessional madness* could not be admitted.

The pathogenic influences of the state of siege were not experienced alone by adults; they were very marked in the development of infants begotten during that period. Under the term "infants of the siege," among the working population, was expressed a recognition of the numerous defects in the development of children born during the latter months of 1871, and likewise the exceptional mortality observed among them. With a view to scientifically verifying this popular opinion, M. Legrand du Saulle's examination resulted in the following:—Thus, in the case of 92 children born during the siege, he found in 64 cases physical, intellectual, or affective anomalies, the remaining 28 were ill developed and sickly. Of these 64, 35 presented physical anomalies, malformations, or perversions of nutrition, 21 intellectual aberrations (imbeciles, idiots, &c.), and 8 were affected with troubles of the affective or moral order. The personal observations of M. Legrand du Saulle are based upon notes furnished by M. Bourneville and Ladreit de la Charrière. It being, therefore, an established fact that a certain proportion of infants begotten during the condition of siege, present certain physical, moral, and intellectual aberrations, it becomes a question to what special pathogenic cause are these to be ascribed. A complex pathology of which the principal elements are alcoholism, inanition, and a psychical state determined by moral shock under the peculiarly distressing conditions. If the popular opinion as to "children of siege" has found a scientific basis in the researches of M. Legrand du Saulle, the question is still not exhausted. It remains to determine, after due consideration and discounting of the hereditary tendency, to what extent as isolated factors in the causation of the morbid phenomena, inanition and alcoholism enter. Again, at what time do these agencies come into activity; is it at the moment of conception, during gestation, or at what period? It is presumable, indeed, that each morbid perversion can only be called into existence at a given period of the evolution of the embryo. It must be admitted that in the case of subjects observed at the hospitals it is difficult to establish these distinctions. We are concerned with the progeny, especially of poor classes, exposed at times to inadequate nourishment, alcoholic excesses, and a special psychical condition begotten of peculiarly depressing conditions. This psychical influence is undoubtedly the least understood, and the most interesting to study.

We have recently had occasion to observe, remarks M. Ch. Péré, in another environment, an important fact in this relationship. A girl of 12 years of age, tolerably well developed, and with regular cranial

outline, came recently under our notice. She had been operated on for left lateral hare-lip. She complains of tic of the eye-lids. She speaks with much difficulty, and indeed, it was not until the age of six that she was able to make herself understood. From time to time she is troubled with incontinence of urine. She reads badly, and writes with difficulty, notwithstanding that great pains have been taken with her education. She is always somnolent, taciturn, and appears from time to time to have fits of vertigo, during which anything which she holds in her hands is allowed to drop. Her father is healthy and sober, and without any nervous antecedents; an uncle and aunt possess an equally good medical history; the grandfather was gouty. Her mother is somewhat romanesque in disposition, but never suffered from pronounced nervous disease. A maternal aunt suffered from chorea without rheumatism. There is no other nervous history. Three children born before this one have been perfectly healthy. The father, who is an advocate, is familiar with the question of heredity in this bearing, and has suffered from a good deal of consequent anxiety. He states as follows:—Everything leads him to infer that the conception of this infant took place on the 2nd May, 1871, about 7 o'clock in the morning; and half an hour afterwards a troop of national guards presented themselves in the sleeping apartment to make a search. The mother became extremely alarmed, was immediately seized with vomiting, and several days elapsed before her excitement had subsided. The household was able to quit Paris, and her pregnancy advanced and was accomplished in a normal manner. In this case there was neither inanition nor alcoholism; and the disturbing element seems alone to have been of a psychical nature. The fact of an aunt being choreic serves to demonstrate a nervopathic tendency on the part of the mother, and explains to some extent the excessive "emotive" which so unfortunately influenced the development of this "infant of the Commune."

Notes on Current Topics.

Exclusiveness in Medical Appointments.

In a letter recently addressed to the *Times*, Dr. MacNaughton Jones calls attention to the existence of a rule in many English hospitals which excludes from their medical staff all practitioners save those who hold some specified English qualifications. Dr. Jones asks:

"Is it not time that such a questionable regulation should no longer be permitted to exclude from fair competition for these public offices graduates of the English, Scotch, and Irish Universities, and Fellows of the Royal Colleges of Ireland and Edinburgh? Such a condition (he says) is contrary to the spirit of the present Medical Amendment Act. It is contrary also to the spirit of modern open and fair competition in all public offices and State appointments." He asks that "a clause might be inserted into the Medical Bill providing that all public and official medical appointments in the United Kingdom shall be open to all duly qualified medical men without any reference to the source from which their degrees or diplomas are obtained."

The complaint uttered by Dr. Jones is perfectly reasonable, and he speaks justly when he represents this ex-

clusiveness as a relic of barbarous times, when there was no security that a practitioner should know his business unless he held degrees from certain institutions; but this unreasoning exclusiveness of which he complains finds an exponent in the person of Dr. Marmaduke Shield, of St. George's Hospital, who writes to the *Times* to defend the system:—

"It is a notable truth," he says, "that the higher examinations of the London Medical Examining Boards are so stringent that no man passes to the goal they guard unless he has worked hard and spent much time and money. It is only natural, therefore, that hospital teachers should be elected from their ranks."

"I am not aware that graduates of the Universities are excluded from the higher posts in the profession. A Government would indeed be 'Liberal' that would interfere with the privileges and decisions of a voluntary society of medical men!"

If Dr. Shield had prepared himself to express an opinion on the subject by examining into the nature of the exclusiveness of which Dr. Jones complains, he would have found that not a few institutions; still insist that their medical officers shall be licentiates of "the College and Hall;" while other institutions insist on membership of Colleges of Physicians and Surgeons. By such institutions the highest degrees of the Universities are rejected in common with licences granted outside London; but it is not wonderful that lay governors—ignorant of the merits of particular degrees—should impose such a limitation when a practitioner of Dr. Shield's standing appears in their defence.

His assumption of the superiority of the examinations of the "London Medical Examining Boards," and as defender of the claim that these Boards should have a monopoly of all hospital teachers, is an amusing display of local self-sufficiency, considering that Dr. Shield has the means at hand—in the reports of the Medical Council Visitors—to satisfy himself that some of these examinations are immeasurably inferior to the examinations of bodies outside Ireland. But assuming, for the sake of argument, that at present no guarantee of sufficient education is to be had outside London, it will be seen that Dr. Shield's position is entirely illogical, because Dr. MacNaughton Jones proposes simply that the exclusiveness of which he complains shall cease with the passing of the Medical Bill, and that none but public and official institutions shall be legally limited as to the qualifications which they demand from their medical staff. The existing condition of affairs will be altogether at an end if the Medical Bill passes, for then the Divisional Board examination will guarantee the competency of the practitioner. This exclusiveness has been most stupidly exercised, because, in many instances, the qualification insisted on by the hospital rule is obviously inferior to those which are tabooed, and so far has this exclusion been pursued that certain Colleges of Physicians have been obliged to institute a new order of members in order to meet the rule which excludes licentiates but recognises members.

THE opening of the new wing of St. Mary's Hospital, Paddington, by the Princess Louise, which was fixed to take place on the 6th prox., has been postponed until the beginning of July, in consequence of the death of the Duke of Albany.

Wanted—a Beverage.

EVEN staunch advocates of temperance are not slow to admit the serious drawbacks from which the cause suffers by reason of their inability to offer any kind of substitute for beer possessing the qualities, less intoxication, for which that beverage is so universally popular. Attempts innumerable have been made to overcome this difficulty; but hitherto all the liquors invented for the replacement of alcoholics have failed to commend themselves to the palate accustomed to the variety of taste and flavour offered in the long list of wines, &c., in general use. With the knowledge of these facts before us, therefore, we could not help but regard with a feeling of anxious interest the goodly array of seductive-looking bottles ranged at the luncheon of the Society for the Study and Cure of Intemperance on Friday last. As far as externals could guide belief, these at least promised to be no unworthy representatives of the clarets, sauternes, sherries, and hocks customarily found at such entertainments; and expectation in this direction was increased by the announcement that these unintoxicating wines had been "imported from their native vineyards" "by the maker," who, moreover, had cruelly subscribed each high-sounding name on the menu by an appetising description of the qualities of each particular beverage. But, alas! for the realisation; and equally for the appreciation meted out to the wines, as shown by the very modest impression made upon the supply. Not a "dead man" could be seen, and our own representative, on returning from the lunch, expressed his opinion of the new "non-intoxicants" in a way that created no kind of desire to become acquainted with them on the part of those who have not as yet accomplished this. In every other respect the meeting and the lunch were exceptionally successful; but the problem to discover a palatable substitute for alcoholic beverages remains still as ever, unsolved. It must be more to the taste than flavoured syrup and water; the so-called "wines" provided on the occasion in question can claim no higher distinction.

Dr. Homans as an Ovariologist.

As a successful operator in cases of ovariectomy, Dr. John Homans, of Harvard University, and the Massachusetts General Hospital, U.S.A., is tolerably well known to British specialists. It may therefore be of interest to state the following facts in connection with his practice, and which formed the preface to a lecture delivered by Dr. Homans at the Harvard Medical School, a report appearing subsequently in the *Boston Medical and Surgical Journal*. Dr. Homans asserted that he had opened the abdomen for various purposes 203 times, and had operated for excision of diseased ovaries 159 times. The first five cases of ovariectomy were done without antiseptic precautions, and they all terminated fatally. The next 100 were performed antiseptically: 87 recovered, 13 died. Since then he has done 54 ovariectomies, with only 4 deaths, the last 30 having all recovered. Operation was declined in only one case that offered, and in this 2,270 pounds of fluid have already been removed by tapping within five years. After describing the preparations to be made for, and the mode of carrying out the operation, Dr. Homans concludes with this warning as to after-

treatment: "The cardinal principle in taking care of a patient after ovariectomy is to give all opiates and stimulants by the rectum until flatus passes the bowels, or until all symptoms of nausea or vomiting have been absent for many hours."

The Micrococcus of Pneumonia.

DR. RUDOLF EMMERICH, assistant in the Hygienic Institution, Munich, some time ago discovered the encapsuled micrococci (Friedländer's) which are characteristic of pneumonia under the flooring of a prison at Amberg. He subjected them to pure cultivation experiments, which gave the result that they really were Friedländer's cocci. He considers that the cause of an epidemic of pneumonia that ravaged the prison in 1880, and from which 46 out of 161 inmates succumbed, is now made plain. He examined the corresponding parts of houses that were free from disease, and in these failed to find a fungus similar to that discovered in the prison.

Hospitals as Nursing Institutions.

At the second meeting of the Hospitals Association, held last Wednesday, the question of utilising hospitals as training-schools for nurses was under discussion. Papers were read by Dr. Bristowe and by the Matron of the London Hospital. The former communicated some interesting experiences of his long connection with St. Thomas's Hospital, and referred to the special facilities there enjoyed for nurse-training through the Nightingale endowment. The views of the lady who succeeded Dr. Bristowe very naturally inclined to raise her special department into importance; and it is not very difficult to perceive that, in spite of protestations as to subservience, Miss Lückes would not be unwilling to have nurse-training regarded as a superior business to either doctoring or doctor-educating. The tendency with modern matrons and the system of sisterdom that attends them is to subordinate efficiency to the demand for "training" of probationers; and none can so well tell the painful shortcomings of those to whom ward work is entrusted under this system, as those who have medical charge of patients in those hospitals where almost daily changes are made in the attendant. It is satisfactory that the tone of the discussion after the papers referred to had been read was very evidently against the aspirations indulged in by Miss Lückes. Naturally, practical physicians and surgeons will think more of the needs of patients, and less of abstract qualities of the ideal nurse, than a lady who, however efficient she may be in an administrative capacity, cannot possibly appreciate the motives which influence the medical mind in its decision as to the requirements of a good nurse. One other point arises too. As at present carried out at the London and elsewhere, women are taught to be nurses on a principle which is held to be economical in the interests of the charity. As probationers, and while paying a certain weekly sum to the hospital, they are taught in the wards at the expense, not rarely, of annoyance to house-surgeon and dressers, whose functions are interfered with by the ignorance of these untrained learners. They replace the old, efficient nurses; and at the caprice apparently of any senior ad-

ministrative official they are hurried about from place to place in the hospital, so that it sometimes happens that within a week three or four different nurses will be on duty in the same ward. Such deficiencies are too great a price to pay for the paltry saving effected; nor can it be said that the vaunted superiority in educational matters possessed by the new order over the old is exhibited in any marked degree that can be noticed. The question, however, is a large and important one, and will probably occupy the attention of the Association yet again.

Osmic Acid Treatment of Peripheral Neuralgia.

DR. EULENBERG, of Berlin, has employed subcutaneous injection of osmic acid in 29 cases of peripheral neuralgia. The dose employed was 7 minims of a 1 per cent. aqueous solution. The treatment was persisted in for periods of from 1 to 6 weeks, and the number of injections made varied from 3 to 14. Of the 29 cases only 7 are reported as cured, viz., 4 of sciatic, 11 of lumbar, 1 of brachial, and 1 of intercostal neuralgia. The success has not been as great as previous trials would lead us to hope for; but supposing that the whole 29 cases had resisted all other methods of treatment, success in 25 per cent. of the cases must have been gratifying—at least to those who were benefited.

Volunteer Medical Association Lectures.

At a meeting of Volunteer medical officers and others, held last week, a proposal was carried to change the title of the Volunteer Medical Organisation, founded by the exertions of Surgeon-Major Evatt, to that of "The Volunteer Medical Association," under which name it will henceforth be known. At the same time it was resolved that a series of lectures should be given in London, at intervals, on subjects connected with Volunteer medical work; and there was expressed a well-founded hope that the theatre of the United Service Institution might be available for this purpose. In conformity with this arrangement, three lectures will probably be delivered during the months of May and June, and invitations to undertake this duty have already been addressed to certain eminent officers connected with the medical military service. In a few days, it is hoped, full particulars will be published of the scheme; but meanwhile it is possible to express sympathy with it, and to predict from it a beneficent result in developing the efficiency of the Volunteer medical service, the condition of which is such as to render such a stimulus very desirable indeed.

IN the principal foreign cities the rates of mortality per 1,000 of the various populations were, according to the latest official returns, as follow:—Calcutta 26, Bombay 25, Madras 76, Paris 28, Geneva 38, Brussels 24, Amsterdam 27, Rotterdam 29, The Hague 22, Copenhagen 17, Stockholm 20, Christiania 16, St. Petersburg 42, Berlin 24, Hamburg 28, Dresden 25, Breslau 28, Munich 31, Vienna 33, Prague 39, Rome 36, Turin 33, Venice 22, Lisbon 27, New York 26, Brooklyn 20, Philadelphia 23, and Baltimore 20.

Total Transposition of Organs.

DR. P. GUTTMANN, of Berlin, demonstrated a preparation from a case of complete transposition of viscera before the Berlin Society for Medicine (Junere Medizin) on March 17th. The case was that of a man, 62 years of age, who died of tuberculosis. The diagnosis was made during life, and completely verified by the preparation shown. Even to the most minute details the transposition was complete. Attention was first drawn to the irregularity by observing that the heart pulsed on the right side, percussion then showed that the liver was on the left, and the spleen on the right. Œsophageal auscultation demonstrated that the cardiac orifice of the stomach was on the right, and the stethoscope showed that the lungs were also transposed. Dr. Guttman had met with records of fifteen similar cases, and in all of them except two the individuals that were the subjects of the abnormality were right-handed, showing that the view held by some that such were generally left-handed was not borne out by facts.

The Separation of Consumptive Persons in the German Army.

A CIRCULAR, dated 13th August, 1882, issued to the Prussian Army respecting the spread of consumption, recommends the military doctors to redouble their vigilance in keeping out soldiers either threatened or attacked with this disease. An immediate return to their homes, or a short holiday to recruit the strength of those showing the symptoms would do much to prevent infection. The circular also states that great care should be taken, especially in the infirmaries and hospitals, not to let those suffering from tuberculosis be with other patients, especially those who are attacked by bronchitis or pneumonia. This order, says the *Revue d'Hygiène*, is very necessary and useful, but we regret not finding among its rules one relating to the disinfecting of the hospitals by burning 30 grs. of sulphur per square yard every autumn, and having a general cleaning out before the winter sets in.

Fermentation Processes in the Human Mouth and their Relation to Caries of the Teeth.

HERR MILLER read a paper on the above subject before the Hygienic Society of Berlin, on the 4th inst., in which he followed up the view first promulgated by him, that the first stage of dental caries was a decalcification of the dental structure produced by acids, which were mainly formed in the mouth as the product of fermentation processes, and that the second stage was a destruction of the softened osseous structure by micro-organisms. The paper detailed his attempts to determine the nature of the ferment present and to isolate it; to ascertain the conditions of its activity as well as the products of it, and the best means of checking it, and finally his attempts to ascertain the influence of the various forms of bacteria that originate in the oral cavity, on certain special and general diseases. He has found that the ferment exists in the saliva, and that it results from the growth of two kinds

of organisms which he has named *a* *Milchsäurepilz* and *b* *Milchsäurepilz*. He thinks these forms may really be one organism, but he has not yet succeeded in developing the one from the other. The acid produced he has ascertained to be a lactate of zinc. He has succeeded in producing rapid caries of the teeth, through the action of the acid generated by the artificially cultivated *leptothrix*. He then sought for a germicide that would check or entirely prevent the growth of the acid forming organism. He found that the following substances possessed such a power:—Corrosive sublimate 1 in 500,000 checked the formation of acid, 1 in 100,000 completely destroyed it. Permanganate of potash 1 in 2,000 checked, 1 in 1,000 completely destroyed it. Carbolic acid 1 in 1,000 checked, 1 in 500 completely destroyed it. Salicylic acid 1 in 125 checked, 1 in 75 completely destroyed it. He thinks a solution of corrosive sublimate of the strength of 1 part to 5 or 10,000 would be a very effective mouth wash and one entirely free from danger. Of the other fungi appearing in the mouth, the author mentioned that of vinegar, and the hay bacillus. The latter was easily isolated and was of interest from the rôle it was suspected of playing in typhoid fever. The spores of the fungus remained capable of development after one hour's cooking in solution of meat extract, and also after longer retention in a .3 per cent. solution of lactic acid. It was not impossible therefore that spores capable of development might find their way through the mouth and into the intestines. He had also met with scattered bacilli of the butyric acid fungus in the oral secretions, and many times a sarcina like alga of great resisting power. Bearing in mind the great number of intestinal affections in which fermentation played a part, he considered that the fungi originating such processes should be attacked in their place of origin.

MR. ANDREW CARNEGIE, the Scotch-American iron-master, has given fifty thousand dollars to the Bellevue Hospital Medical School, New York, to encourage medical discovery especially in connection with the germ theory, with a view to the prevention of disease.

THE deaths registered last week in the principal large towns of the United Kingdom corresponded to an annual rate of 22.5 per 1,000 of their aggregate population. The death-rates in the several towns were:—Derby 13; Brighton 14; Leicester 16; Huddersfield 17; Hull 19; Plymouth, Birmingham, Blackburn, Birkenhead 20; Edinburgh, Newcastle-on-Tyne, Bristol, Salford, London, Sunderland 21; Halifax, Bradford 22; Sheffield 23; Norwich, Liverpool, Glasgow, Portsmouth, Preston 25; Nottingham, Cardiff 26; Leeds, Oldham, Wolverhampton, Manchester, Bolton, Dublin 28.

THE highest annual death-rates last week in the large towns from diseases of the zymotic class were:—From whooping-cough, 2.4 in Bolton, and 1.7 in London, in Liverpool, and in Manchester; from measles, 4.7 in Wolverhampton, 3.1 in Portsmouth, and 2.8 in Nottingham; from scarlet fever, 3.1 in Sheffield, 2.1 in Preston,

1.7 in Cardiff, and 1.6 in Leeds; and from "fever," 1.2 in Bradford. The 30 deaths from diphtheria included 18 in London, 4 in Glasgow, and 2 in Dublin. Small-pox caused 11 deaths in London, 2 in Liverpool, 2 in Newcastle-upon-Tyne, 1 in Wolverhampton, and 1 in Sheffield.

Scotland.

[FROM OUR NORTHERN CORRESPONDENTS.]

A COLLEGE OF SURGEONS FOR SCOTLAND.—There is every probability of a union taking place between the College of Surgeons of Edinburgh and the Glasgow Faculty of Physicians and Surgeons, the result being one College of Surgeons for Scotland. Such a consummation is devoutly to be hoped for, and we trust before long to be able to announce that the union has taken place.

LEGACIES TO GLASGOW MEDICAL CHARITIES.—By the will of Miss Hunter, of Hunterston, the following sums have been bequeathed:—To the Glasgow Royal Infirmary, £100; to the Glasgow Blind Asylum, £100; to the Glasgow Deaf and Dumb Asylum, £100.

MORTALITY IN GLASGOW.—The deaths in Glasgow during the week ending with Saturday, the 19th inst., were at the rate of 25 per 1,000 per annum of the population, as compared with 29 in the previous week, and 34, 27, and 27 in the corresponding periods of 1883, 1882, and 1881.

HEALTH OF EDINBURGH.—The mortality in Edinburgh for the week ending with Saturday, the 19th inst., was 98, and the death-rate 20 per 1,000. Diseases of the chest accounted for at least 50 deaths, and zymotic causes for 14, of which 1 was due to fever, 3 to scarlatina, and 3 to measles, the intimations of these diseases for the week being 16, 23, and 47 respectively.

THE OUTBREAK OF SMALL-POX AT GLASGOW.—Dr. Russell's last fortnightly report states that there had been four deaths from small-pox registered, all of which took place in the hospital, two belonging to the Northern District, one to the Eastern, and one to the Southern. Three of the four cases were unvaccinated. There had been 21 cases of small-pox registered, as compared with 24 in the preceding fortnight. Of these 12 were from the Eastern district, four in the Northern, three in the Southern, one in the Western, and one in the Central. All were removed to the hospital excepting two.

THE LATE TERCENTENARY.

THE Edinburgh University Tercentenary has come and gone, and we cannot help thinking, while we are in some respects hostile to the Scotch University system, that it furnishes a hopeful augury for the future, apart from the pomp and self-gratulation begotten of the occasion. It has brought together almost from "China to Peru" representatives of various nations and professions, the noble utterances of many of whom showing that there are higher interests and federations than those of country—the claims of science and the federation of humanity. A sour people, inhabiting a damp climate "contiguous to the melancholy main," and only natural when three-fourths under the influence of their national beverage, the Scotch have done not a little to further the interests of humanity and the emancipation of intellect. James Watt, Robert Burns, John Knox, and Adam Smith have been powerful preachers in their day, of necessity in advance of the times in which they lived. On

the part of the distinguished foreigners who recently visited Edinburgh, their knowledge of our language, literature, and history were highly creditable to them, as it was flattering to us. Without intending any invidious distinction we may mention the names of Count Saffi of Bologna, Beets of Utrecht (for theologians even we have our meed of praise), Straszewski of Cracow, and, belonging to our own profession, Virchow, Helmholtz, and Pasteur. There can be no more effectual humanising agency than the assembling together of men of culture of all nations; such meetings are yet too infrequent; and not only is our profession, but Europe is under an obligation to the University of Edinburgh for the recent Tercentenary demonstration. It is by such means and such influence that the day-dream of all good men will come to be realised, when justice shall bind the nations together, and "man to man the world o'er shall brothers be and a' that."

In addition to the addresses from sister Universities which were presented by the delegates at the meeting in the Synod Hall, many more have been sent direct to the University. A large number of the Continental addresses are most beautifully and artistically illuminated, resembling in style the missals of the old monks. It has been suggested that before being laid aside, the addresses should be displayed for the inspection of the public; and there is a possibility of that being done by the University authorities.

THE Principal of the University has received the following letter from a gentleman who does not at present wish his name to be published:—"I cannot leave the city without personally tendering you, and those associated with you, my thanks for giving me an opportunity of joining in a celebration that I would have been most sorry to have missed. You have the strongest claims on the patriotism of all natives of Scotland, and more especially on those of Edinburgh. With every good wish for the future progress of the University, and as an earnest of that wish being sincere, I beg you will place my name as a donor of £500 on your next list of subscribers to the fund for completion of your hall, &c."

As a *souvenir* of the celebration, Dr. Maurice Straszewski, Professor of Philosophy in the University of Cracow, and delegate from that University on this occasion, has dedicated to the University of Edinburgh a work he has just published on the origin and development of pessimism in India. The book is in Polish, and is prefaced with a Latin address in which its scope and purport are explained. An English edition will, we understand, shortly be published. Professor Straszewski is also the author of works on the present state of philosophy and its relations to other sciences, and on the philosophy of Spinoza.

THE articles on the "Rise and Progress of the University of Edinburgh" which appeared a few weeks ago in the columns of our contemporary, the *Scotsman*, have been republished in a handsome volume by Messrs. Blackwood & Sons with the title of "Oure Townis Colledge." The articles are characterised by great breadth in the treatment of the subject, and the past dealings of the Senatus with the Town Council are shown in a light which certainly do not redound to the credit of the former.

UNDER the title of "Tercentenary Celebration—the Procession," Mr. G. P. Johnston has published a series of groupings of the Edinburgh professors, some of the extra-mural lecturers, and other eminent men taking part in the festival, accompanied with what purports to be a versified description. The letterpress is very poor, and as for the sketches, while some of the portraits are sufficiently recognisable, the identi-

fication of others will be found to require considerable ingenuity. The best of the series is certainly that of Professor Simpson in the garb of a monthly nurse wheeling in a perambulator two chubby babies—Dr. Berry Hart and Dr. Halliday Croom—the latter dangling from a stick a bladder, on the condition of which during parturition he has written so recently and so well.

Literary Notes and Gossip.

"The Urine in Health and in Disease, together with its Chemical Examination," by H. Aubrey Husband (Livingstone, Edinburgh), is a small volume which may be carried in the waistcoat pocket. The book is neatly got up, and is illustrated by several plates, giving the most usual deposits found in the urine.

"Selections from Essays on Health Culture and the Sanitary Woollen System," by Gustav Jaeger, M.D., is a collection of Essays written at various times by the author, and apparently with the object of advancing the sale of Dr. Jaeger's woollen manufactures, for it is published by the Doctor's Sanitary System Woollen Company, Limited. But apart from its evident object, the book contains many useful hints and suggestions which no one would be the worse for knowing and putting into practice.

THE following specimen of editorial courtesy is 'amusing, if nothing else. The *Medical Age* of New York says, *Le Moniteur de la Policlinique* calls the leading medical journal of this country a "red-skinned, Yankee cocoanut, without education, without wit, without intelligence." How truly is a prophet not without honour save in his own country! The *Medical Age* retorts with studious politeness that *Le Moniteur* is educated, witty, and intelligent—doubtless as education, wit, and intelligence go in France.

IN so extensive a fire as that which occurred a few days since in Paternoster Row—the centre of book-printing and book-selling London—it was not to be expected that medical authors would escape its effects more than others; but so far we are delighted to ascertain that but two instances, and these not of a serious nature, resulted. The MS. of the second volume of Dr. Morell Mackenzie's work on "Diseases of the Throat and Nose" was entirely consumed, but fortunately it had been put in type, and can be reset from proofs in the author's possession. The other case was that of Dr. MacNaughton Jones, who lost 300 out of 500 copies of his little work just issued on "Spinal Deformities."

THE announcements of new books for the coming month are principally confined to health treatises and pamphlets: these are legion, in anticipation of the coming exhibition to be inaugurated next week. The public ought certainly to stand in no need of doctors if they digest only one-tenth of what is promised. Of medical works proper we have volume III. of Roscoe and Schorlemmer's Chemistry, a Manual of Diseases of Women and Uterine Therapeutics by Dr. Macnaughton Jones, Physiological and Pathological Chemistry by Dr. Cranston Charles, Syphilis and Pseudo-Syphilis by Mr. Alfred Cooper, *Materia Medica* and Therapeutics by Dr. Bruce, and a new edition of Keetley's Index to Surgery.

TO amateur ornithologists, especially those having a *penchant* for parrots and birds of like species, "Parrots in Captivity," by Dr. W. T. Green (Bell and Sons), now appearing in monthly parts at a shilling, will possess great attractions. Such a work simply surprises us with the amazing variety of colour and species found in this gorgeously plumed favourite. Each monthly part of Dr. Green's venture contains three plates of rare beauty and exquisite workmanship, and we can only hope that its great cost will be more than met by the success it undoubtedly merits. Our *compatriots* contributions to ornithology are unique, and so far as we are aware more extensive than any other member of the profession, and it affords us much pleasure

to congratulate him that in the midst of a busy professional life he can find time to instruct a wider sphere in these interesting by-paths of science.

In a review of Dr. Ross's "Treatise on Diseases of the Nervous System" which recently appeared in the *Philadelphia Medical Times*, the author of the notice thus sarcastically alludes to the well-known weakness of American publishers:—"We are very glad to note, as an indication of growth of honesty among our American publishers, that, although the title-page bears the impress of a New York firm, the book was printed in Manchester, where its wretched muslin covers indicate that it was also bound." For ourselves, however, we fear the reviewer's congratulation on the improvement in his countrymen's morality towards English authors is very premature. Pirating a voluminous work like Dr. Ross's would mean an outlay that even New York publishers would fear to make, associated as it surely would be with the certain risk of retaliatory measures on the part of its legitimate owner.

We are glad to notice the controversy now going on in the United States on the subject of copyright law, for only by such discussion can we ever hope for a fair interchange of brain and money value between the two countries. Hitherto America has had it all her own way, she would allow no law or International courtesy to stand in her run of wholesale piracy, and labours of European authors have been seized and reprinted without fee or reward for the enrichment of American publishers. Lately some of the leading houses in that country, to their credit be it said, have voluntarily offered and paid compensatory sums to modern English authors, notably those in our own profession, for the right to reprint their works, although possessing the power under American law to do so without such permission. We regret, however, to meet with an exception to this honourable change of ideas in the person of Mr. H. C. Lea, one of the largest of Transatlantic publishers, who, in a leaflet to hand, advocates the narrow-minded and unjust principle of non-importation of English manufactured books, so that all copyright works shall be manufactured in the States.

This handy little volume, "Therapeutische Notizen der Deutschen Medizinischen-Zeitung, 1880-83," is somewhat of a novelty in journalism, inasmuch as it takes the place of one issue of the paper, that of April 14th, 1884, No. 30, and is furnished free to all subscribers. It contains in a very abbreviated form references to all the therapeutical notes that have appeared in the journal during the four years 1880 to 1883. In addition to this, in order to make the work as complete as possible, all the drugs of the German Pharmacopœia, second edition, are introduced with their single and maximal doses, as well as other drugs in ordinary use not included in either the *Zeitung* or *Pharmacopœia*. The notes are given under the headings both of drugs and diseases. We have no hesitation in saying that the notes will prove reliable and useful.

THE profusion of door-plates and coloured lamps at the residences of suburban practitioners in our day brings to one's thoughts the barber-surgeon's pole of a century ago, when over the surgeon's door or window was invariably seen the surgical stick of three colours; blue, to represent venous blood, red, arterial blood, and white, the bandage for use after bleeding. The coloured lamps of the present day, however, have no such significance, as various hues are requisitioned according to the taste of the owner, and the lamp is merely suggestive to the uninitiated at night of the presence of a medical man in case of need. The stick here referred to is of great antiquity, illuminations thereof being found in missals as far back as the reign of Edward the First. To lovers of folk-lore the papers of Mr. Cordy Jeafferson now appearing in the *Leisure Hour* on "Doctors out of Practice" will have an especial attraction.

ACCURACY of expression is generally regarded as much to be desired in all matters pertaining to medicine and medical institutions. It may very well be doubted, however, whether the medical officer of the Cathcart Parochial Board, if questioned on this subject, would be found an enthusiastic upholder of the ideal terminology, for, in the monthly report of the Board in question, the following unperiphrastic mode of communicating information as to the health of the district occurs:

"The Inspector then proceeded to read the medical officer's report for the month of March. There were, he said, 'nineteen cases on the roll. The doctor had cured five and killed one, leaving only thirteen on the roll.' He meant to say one had died." This inspector ought henceforth to be retained in the permanent service of the State, with a special office, adjacent to the Local Government Board's central bureau.

MR. JAMES CANTLIE, F.R.C.S., has printed for circulation a valuable little essay on "The Effects of Certain Anatomical Relations," which he lately delivered in the form of a lecture to the Medical Society of Charing Cross Hospital. It is full of interest, and is very usefully suggestive of reflections on certain points of common observation during dissection, but the *rationale* of which does not, as a rule, explain itself unsought to the mind of the student. Such, *e.g.*, as the relation in position of light-weighted and heavy viscera in the body, the constant parallelism of veins and arteries, and a peculiar coiled appearance of nerves in rest, which Mr. Cantlie has himself been the first to notice. The observations contained in the paper deserve a more prominent record than the fugitive publication they have received, and it is to be hoped Mr. Cantlie will redeem the promise with which he concludes, to continue the subject at greater detail on a subsequent occasion.

"Æsthetical Sanitation" (Stanford) is the title of a small brochure by Mr. William White, dedicated with permission to the Duchess of Teck. This book is a reprint of some papers contributed by the author to the columns of the *British Architect*, where they appear to have received such acceptance as to induce the writer to publish them in book form. They tell the "twice told tale" of the absurdity of many of our "daring" fashions, and show in plain and readable language the danger of many of the attempts at the so-called improvement of the human form divine. We commend this little book to those young ladies who are ignorant of the author's only safe rules as to the tightness of a dress, and would humbly request them to discard every dress which will "open in the smallest degree when the buttons, hooks and eyes, or laces are undone, and in which the arms cannot be at will raised, lowered, thrown backwards or forwards, turned in any direction, without perceptible drag on the dress."

"Universal Attraction and its Relation to the Chemical Elements, the Key to a Consistent Philosophy," by W. H. Sharp (Livingstone, Edinburgh), is an attempt to show that Newton did not know everything about the laws of Nature, and that Newton's law of attraction is not the law of universal attraction, but that there is a higher law, and that the different atomic weights of the elements are not due to different kinds of matter, but to the difference of the earth's attraction upon these atoms; that as all atoms are supposed to occupy unit space, logic suggests that the mass put into each will be unit mass, and therefore the atomic densities will be unit densities. To compare the mass of the atoms we are taught to do so by weighing, but *not directly*, but through the medium of the earth. But this weighing involves the assumption that the earth's attractive force acts in the same manner upon the different kinds of atoms. The author then suggests that each atom has its own atomic vibration, which gives character and weight to the atom, and as a result differences in chemical compounds. We hope that we have given the author's views correctly, and would commend the book to our readers who are interested in the study of ingenious theories.

IN a pleasantly gossiping article in the April number of the *Leisure Hour* we once more come across that celebrated but eccentric surgeon Dr. Monsey, who thrived during Sir Robert Walpole's time, one of whose special devotions was the drawing of teeth by the aid of catgut attached to a bullet. It is said he even drew several of his own bicusps by this method for practice. It was not, however, an easy matter to persuade patients to submit to this rough but speedy method. Once a gentleman, who had agreed to make trial of the novelty, and had even allowed the apparatus to be adjusted, turned craven at the last moment. "Stop! stop!" he exclaimed. "I've changed my mind." "But I haven't changed mine," answered the doctor, pulling the trigger, and the tooth flew out of the window. Even at this distance of time it is curious to discover that the patient of this comedy was his grace the Duke of Grafton, and that, to avenge himself for the loss of a place

in the Lord Chamberlain's gift, the operator attached the catgut to the wrong tooth. * *

NEW BOOKS AND NEW EDITIONS.—The following have been received for review since the publication of our last monthly list (March 26th):—*The Treatment of Spinal Curvatures*, by H. MacNaughton Jones, M.D. *The Influence of Heredity and Contagion on the Propagation of Tuberculosis*, by M.M. George Fleming, A. Lydlin, and Van Harten. *Diabetes Mellitus*, by H. J. Philpot, L.R.C.P. *A Year-book of Therapeutics for 1883*, edited by R. W. Amidon, M.D. *A Year-book of Surgery for 1883*, by C. J. Knight, M.D. *Corpulence and its Treatment*, by Dr. Ebstein; translated from the German by A. H. Keane, B.A. *Ambulance Handbook for Volunteers and others*, by J. A. Raye, L.R.C.P. *Memoirs of Life and Work*, by C. J. B. Williams, M.D., F.R.S. *Disease Prevention*, by Cornelius B. Fox, M.D. *A Treatise on Chemistry*, by H. E. Roscoe, F.R.S., and C. Schorlemmer, F.R.S., Vol. III. *Cremation*, by Sir Henry Thompson, F.R.C.S. *The Asclepiad*, edited by Dr. Richardson, F.R.S. *An Index to Surgery (2nd Edition)*, by C. B. Kestley, F.R.C.S.

THE DETAIL OF THE MEDICAL BILL.

THE form which the agitation in favour of the Bill has taken is extremely unsatisfactory to us, because it is obvious to us that some of the leaders of this agitation do not show any disposition to acquaint themselves with the contents of the Bill, as a precedent to suggesting reasonable improvements. What the origin of the detail of the measure may have been we cannot say, but it bears on it the imprint of the hand of someone who was acquainted with the London College of Surgeons, some other person who had the Scotch Universities in his eye, and of a technical bill-drawer who understood nothing, and probably cared nothing whatever how the Bill might work. Consequently we have a measure in which the third hand has combined the diverse views of the two advisers, and a muddle has necessarily resulted. As an example of this condition of things we may select the clause which deals with the distribution of the surplus funds in hands of the Divisional Board, which is clearly made to fit the Hunterian Museum, and is not only inapplicable, but totally incomprehensible, to all Colleges outside London. Again, the clause which accords special money privileges to University undergraduates is made suitable to such Universities as Oxford, Cambridge, London, and Dublin, but totally inapplicable to the Royal Irish and several of the Scotch Universities. And these are only examples of errors of detail with which the Bill bristles.

We do not in the least make this complaint as a reason against the passing of the Bill, for if faults of detail were to be taken as cause for throwing out a measure no Bill would ever get through Parliament. Every Bill is open to the same objection, and the course uniformly pursued is to assert the broad principles of the measure, as has been done in this case, and to proceed then to make it perfect in its parts, an object which is effected both by compromise and by fighting out the disputed points in committee. The more in the way of amendment has been done by previous compromise and conciliation, the less remains to be done by wrangling across the floor of the House of Commons, and every day's experience shows us that nothing is so fatal to the advancement of a Bill as the want of previous mutual understandings.

In the case of the Medical Bill it seems that every attempt to amend its many imperfections will be the subject of a bitter fight in the House, and that its passage through the Committee stage must therefore be stormy, turbulent, and slow. For this three parties are to blame, the licensing bodies which have asked too much concession, Mr. Mundella, who has refused to listen to any compromise

or change whatever, and lastly, the promoters of the Bill, who seem to have taken no steps to bring about a *rapprochement*, simply because they have never taken the trouble to examine carefully the contents of the Bill or the reasons urged for amendment. We go further and say that they have done immense harm to the cause of medical reform, and have thrown the most serious hindrances in the way of the measure by the line they have taken, because, instead of attempting to solve difficulties and remove stumbling-blocks, they have devoted themselves to dinning into the ears of the Minister the assurance that the profession is fully satisfied with the Bill as it stands, that the opinions of the licensing bodies should be wholly ignored in the settlement of the question, and that their opposition in Parliament is not worth considering. None of these assurances are justified by the facts. The profession, so far as they know the details of the Bill, are not satisfied, and the less meagre their information becomes, the more they recognise faults needing to be remedied, and, if it should pass as it stands, we believe that those who have kept them in ignorance will have a heavy reckoning to answer for. The licensing bodies, as a whole, are not deserving of the harsh treatment which the Bill would mete out to them, inasmuch as they have not all participated in the misdeeds which the Bill seeks to make impossible. Moreover, they are not by any means to be disregarded as political opponents, but, on the contrary, are very much to be feared, and, without doubt, could throw out the Bill if they acted together, and if the Government did not care to make it one of their primary measures.

The policy of the promoters has been, in our opinion, disastrous and most imprudent, but it is not too late to remedy it, and we hope it will be at once changed for one of conciliation and compromise with the licensing bodies. That it has been the outcome of an insufficient knowledge of the detail of the Bill is obvious from the misconceptions which find expression in journal articles inspired by those who have adopted this policy.

In one medical contemporary we noted, last week, an exposition of editorial opinion which clearly showed that the writer had not fathomed the depth of the University fee clause, and that his purview of the effect of that clause did not extend beyond the institutions with which he was personally connected; and in another journal of the same date we note that the effect of the anti-quack clauses of the Bill has been entirely misconceived.

The profession is, in fact, asked to "shut its eyes and open its mouth and see what the king will send," the licensing bodies are adjured to trust in Providence and be content, and the Government is entreated to do battle for medical reform without considering the strength of its opponents.

Few Bills were ever carried by such means as this; and none, if so carried, ever proved satisfactory as a final settlement of disputed questions. If the Medical Bill is to be carried in its present form, it can only be by the determination of Government to make it a primary question; and, if so passed, a year will not elapse before an agitation will arise for amendments which are now disregarded.

THE Queen has conferred a Companionship of the Bath on Mr. Arnold Royle, M.R.C.S., &c., who has been in medical attendance on the late Duke of Albany since 1875.

WE learn that the Harveian Society of London has unanimously conferred upon Dr. Banks, of Dublin, Physician to Her Majesty, President of the Irish Academy of Medicine,

and Regius Professor of Physic in the University of Dublin, the honour of electing him Corresponding Member of the Society, a distinction which does much credit, not only to Dr. Banks, but to the Society itself.

Correspondence.

HOPE AS A REMEDY AGAINST DISEASE.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR.—The annotation in your journal of the 23rd inst. brings to my knowledge two facts: First, that an article entitled "Hopefulness in Prognosis and Professional Manner—a Remedial Measure" appeared in your columns on April 16th; and, second, that you half suspect me of plagiarism, because a letter of mine on "Hope as a Remedy against Disease" appeared in the *Times* of April 17th. I agree with you that the "almost simultaneous appearance" of the article and the letter is a very curious coincidence. You will, however, I am sure, acquit me of any literary theft, either of subject or matter, when I tell you that my letter was written and posted to the editor of the *Times* on the morning of the 15th inst., so that I could not possibly have stolen your ideas or arguments even had I been capable of so paltry an act of dishonesty.

As regards the "imputation of unworthy motives," to which you think I have laid myself open by addressing my remonstrance against hopelessness to a lay journal instead of to a professional periodical, I must ask you to remember that the despair I deprecate is something in the mind of the patient, not in that of the doctor! I will not, however, discuss the question of propriety, or try to defend myself. In the course of a somewhat long experience of public life I have always found it best to act on one's own inner sense of right and to leave the consequences. I have found that the phrase "the world is very censorious" simply means that the person using it desires to veil his own censoriousness under the imputation of that quality to an intangible entity indicated as "the world." I am, in a very exclusive sense, a consulting physician, and those of my professional brethren who disapprove of my conduct in the matter of my writings or in any other way have the remedy in their own hands. They can discontinue the practice of calling me in and they can refuse to meet me. I am neither careless of my own reputation nor envious of that enjoyed by any other physician. I have never said or written anything to the detriment of a brother practitioner; and in all my dealings with professional men I have tried to do as I would be done by. It is a consolation to me to know that there are *some*, at least, who do not think ill of me or impute "unworthy motives." I am sorry to have offended you, Mr. Editor, and the more so because this is the second occasion within a few weeks on which you have "alated" me. Do not judge me either insolent under rebuke or impatient of correction. I am sincerely grieved to have angered you. Life is too short for fruitless contentions.

I have not yet read your article, but I shall now do so with great interest; and it will give me much pleasure to find that we are agreed as to the monstrous folly—I could use a stronger word—of frightening patients to death with our pathological prognoses. No medical man who has had any considerable experience of consulting-room and bedside practice can fail to know that such poor *guesses* as we can, at the best, make with regard to the duration and issue of morbid states and even of organic diseases, are not of a nature to be treated as *knowledge*; and, as I have said elsewhere, I say here, patients are ill-advised to be depressed by them. There are, within my own knowledge, persons now living, and likely to live, whose lives I, in common with other practitioners, credited with a very brief expectancy twenty years ago. They had "tubercle," or "cancer," or "heart" or "kidney" disease, and doubtless, they have these mortal maladies still; but, despite our prognoses, they did not die twenty years ago, when disease appeared to be active as well as "incurable," and it is certainly quiescent now and matters nothing that it is still incurable. Moreover, they began to mend—and this is a point on which I wish to lay especial stress—when they got over the scare we gave them and ceased to take the precautions we enjoined. So far am I from thinking patients afflicted with organic disease are the better for being under treatment,

that I would infinitely prefer if I had any such malady myself not to be treated at all! This is the moral of the doctrine I am trying to teach, and I must hold to it even though it be so heretical that you feel bound to excommunicate

Yours faithfully,

16 Welbeck Street,
April 23, 1884.

J. MORTIMER GRANVILLE.

P.S.—Since writing the above I have seen your article, and I must ask leave to say that it is, in my judgment, one of the soundest and most useful I have ever read. I only wish I had seen it before I wrote my letter. You have written for the medical man the complement of what I wrote for the patient. There is only this difference: you seem to have been thinking of acute cases. These were in my mind too, but I wrote *chiefly* for those poor creatures who go about doomed and miserable with the brain-burden of an ever-present consciousness of carrying about in their bodies the poisoned barb of the last enemy. When I wrote it was under the pressure of some quite recent impressions of the mischievous effects of "opinions" expressed by consultants, after a very brief examination, which I found to be practically "sentences of death." Against the wickedness—yes, I will say *wickedness*—of such declarations I protest. They are the outcome of a pretentious spirit that ought to be exorcised. The public need to be warned against the men who, because they find a little dulness under the clavicle or prolonged expiration, prate of "consumption," or who, because they find a trace of albumen in the urine, dismally portend death from kidney disease. Why, Sir, there are medical men in good health who can show from fifteen to twenty per cent. of albumen in their own urine, and have been able to do so any time for fifteen years past and who are, nevertheless, well and hearty yet; and they do not either starve themselves by avoiding "brown meat," or lead the wretched life of your "patient with renal disease." Every step forward in science shows the folly of some old belief. Five-and-twenty years ago flattening of the sub-clavicular region was supposed to indicate active disease; we know now that it rather bespeaks an attempt at recovery. I might instance other proofs of our fallibility. Let us be more careful how we give bad prognoses; and let those who do not *feel* ill decline to think they must be so simply because "the doctor" talks of "organic disease" or an "incurable malady."

I leave the conversion of the profession, to a right way of thinking and speaking, to you. Meanwhile, leave me to put the patients on their guard, and to rescue the victims of "science" as best I may.

J. M. G.

THE COMING MEETING OF THE BRITISH MEDICAL ASSOCIATION AT BELFAST.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR.—Will you kindly permit me to correct some mistakes which appeared in your leading article on "The Coming Meeting of the British Medical Association" in your issue of the 2nd inst., and to endeavour to remove some misapprehensions that may have been created thereby. First, as to the statement "that the northern capital of Ireland had put itself in the post of honour to the exclusion of its own guests." I beg to state that all appointments of officers are made by the Council of the Association in London, and not by the local committee, so that it does not rest with that body to place itself in any post of honour. As to the appointments that have been made by the Council of the Association, out of eight Presidents of Sections only two have been selected from Belfast, of eighteen Vice-Presidents of Sections three have been selected from Belfast, and as regards Secretaries of Sections it has always been considered desirable that one for each section should be resident at the place of meeting, thus eight secretaries of sections have been appointed from Belfast, not because they desired to put themselves in the post of honour to the exclusion of their guests, but because they were willing to undertake a task of self-denying self-sacrificing toil to render the meeting of their guests as pleasant and as successful as they could. Again, as to the statement "the studied omission of Dublin from a place in the coming meeting is, we are aware, regarded as a deliberate intimation from Belfast that the presence and co-operation of the profession in Dublin is not desired." I take the liberty of assuring the profession in Dublin that nothing could be

more remote from the wish or desire of the profession in Belfast, or of the intention of the Council of the Association. No such omission has been made, and the selection from Dublin to one of the highest posts of honour the Council had to bestow—the Reader of the Address in Obstetrics—might have been accepted as proof of this; besides, the Presidency of one of the Sections, and the Vice-Presidency of another were offered to Dublin and declined. It will be thus seen from the appointments already made and those offered to Dublin that every desire existed to place it in the position which its eminence in the profession both merits and commands.

Yours, &c.,
Belfast, April 10th, 1884.

JOHN MOORE.

[We believe that though, technically, the selection of Presidents and Vice-Presidents of Sections rests with the Central Council of the Association, the recommendations of the local organisers of the meeting are almost always confirmed, and they are the virtual appointers. We, of course, accept the disclaimer of Dr. Moore with reference to the apparent snubbing of the profession in Dublin, and we are bound to believe that the exclusion of which we complained was an inadvertence. But that there was such an exclusion no one who looks at the list of officers of the coming meeting can doubt. Here is the list of officers selected from Dublin:—Medical Section, one Vice-President; Surgical do., none; Obstetric do., none; Public Medicine do., none; Ophthalmological do., none; Physiology and Pathology do., none; Therapeutical do., one Vice-President; Psychology do., one Vice-President. This list cannot be made sufficient by the fact that a Dublin obstetrician is asked to deliver the address in his own subject, but even this very limited recognition of the professional forwardness of the Irish metropolis is made the subject of attack by a party in Belfast, for whom we do not at all hold the local committee responsible, but who, no doubt, consider themselves the exponents of Belfast opinion. Without doubt the initial organisation of the Belfast meeting has been very unfortunate.—Ed.]

PAPER VOTING IN THE IRISH COLLEGE OF SURGEONS.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—The annual election of the Council of the College approaches, and I have reason to believe that in anticipation of it a letter will shortly be addressed to the Fellows in which the Council will be attacked for having neglected to give effect to the recommendation passed by the College that votes for Council election should henceforth be given by the Fellows by means of papers sent through the post, the Fellow who votes being absent. I understand that a voting list is in preparation, which omits the names of all councillors who are supposed to be hostile to this method of voting, and substitutes those of opposition candidates. Under these circumstances I think it well to anticipate the statements which may be made by explaining to the Fellows at large why it is that their recommendation has not yet been acted upon by the Council.

The substitution of *absentia* paper votes for personal suffrage requires a change of the Charter of the College, for which an application to the Secretary of State is necessary. As a first step the recommendation of the Fellows at large must be obtained (which is supposed, in this instance, to have been done), and, as a second step, the Council must consider the recommendation and approve. Thus a recommendation from the Fellows passed in the beginning of June cannot be considered in Council until some weeks later, and if details have to be settled by a committee and reconsidered by Council, perhaps more than once, it will be easily understood that considerable delay takes place in carrying the matter further, even if the Council is ever so anxious to make progress.

Now for forty years, from 1544 up to 1883, no change of Charter was asked for, but in the early part of last year the Council resolved to ask for a change which would alter the mode of electing professors, and that change having been

agreed to in March, received the approval of the College at large in June, at the same meeting at which the paper voting took its first step. Thus the change for paper voting was only first proposed at the moment when the change for professional election was finally approved, and it is, therefore, easy to understand that the latter change could be, and was, immediately proceeded with while the former had to be debated in Council, and its details worked out in committee. But, notwithstanding this, the change of method of professorial election did not obtain the sanction of the Secretary of State until nearly five months afterwards, and with that sanction came an account for £140 for fees to the Attorney General and other officials in carrying out the alteration of Charter. Naturally the Council considered it unwise to hurry forward a single further change without considering whether there might be other emendations necessary which might be obtained at the same time and without additional cost. Accordingly the Council remitted to a committee to examine the Charter and see in what respects it needs alteration, and that committee met several times and agreed on sundry proposals; but then came the Medical Bill, which unsettled everything, and it became obvious that it would be inadvisable to incur the heavy expense of further alterations until it was ascertained whether a new state of affairs would arise which would involve a recasting of the entire Charter. Thus it came about that the proceedings of the committee went no further, and I believe the Fellows will see that the Council acted properly in delaying action as they are accused of doing.

Though I am aware that I am myself the subject of special attack, I think it unnecessary to make any apology for my action. I opposed, in the presence of the Fellows, a change which would rob the provincial Fellows of their influence in the College. I resisted, in the Council, the confirmation of the recommendation made by the College at large because I believe that that recommendation was snatched by a chance vote of an insignificant minority, and does not express the deliberate opinion of the College. But when the Council decided against me I made no further opposition, nor did any member of the Council, and if it should be represented that the Council as a whole, or any of its members, have deliberately obstructed the arrangements for paper voting, that representation will be untrue.

I am, &c.,

ARCHIBALD H. JACOB, M.D. Dub. Univ., F.R.C.S.I.

Royal College of Physicians of London.—At the ordinary meeting of the Council of this College, on Thursday last, the President, Sir William Jenner, Bart., in the chair, Mr. J. Bland Sutton, of the Middlesex Hospital, was declared the successful competitor of the Murchison Scholarship on the recommendation of the examiners. There were fifteen competitors for the prize, and the success of Mr. Sutton is therefore the more pronounced. The name of Mr. R. F. Fox was also honourably mentioned in this connection. The other business transacted was of a routine character, and comprised a refusal of the request from the Trustees for Manufactures in Scotland for the loan of some of the College portraits. The by-laws approved at the last meeting were formally enacted; and a committee was appointed to superintend a banquet to be given in accordance with the testament of Harvey.

The Council of the Irish College of Surgeons.—In addition to the candidates for seats on the Council of whom we spoke last week, Mr. Stokes, Professor of Surgery in the College, and Dr. Carte, of the Royal Hospital, Kilmainham, Dr. W. A. Elliott, of the Whitworth Surgical Hospital, Dr. Meldon, of Jervis Street Hospital, and Dr. C. H. Robinson, will, we understand, present themselves for the suffrages of the Fellows. There are now eight candidates in addition to those members of the outgoing Council who propose offering themselves for re-election.

The Election of Examiners at the Irish College of Surgeons.—The annual election takes place on next Tuesday, and several competitors, in addition to the out-going Courts, present themselves. Dr. Kendal Franks, of the Adelaide Hospital, Mr. Ormsby, of the Meath, Dr. Richard Hayes, of Stevens's Hospital, and Drs. Kilgarriff and Boyd, of the Mater Misericordiae, have announced their intention to offer themselves. The election will be by the entire Council.

Society for Relief of Widows and Orphans of Medical Men.

—A quarterly court of the Directors of this society was held on Wednesday, April 9th, Sir James Paget, Bart., President, in the chair. A letter was read from Sir George Burrows, late President, in answer to resolution passed at the last court on his resignation of the Presidentship. The death of a widow receiving £50 per annum was reported. There were no fresh applications for relief. Four new members were elected, the deaths of two announced, and the resignation of another. The half-yearly applications from the widows and orphans on the funds were read, and it was resolved that a sum of £1,162 be granted at the next court to 57 widows, 5 orphans, and 3 recipients from the Copeland fund. It was also resolved that Mr. James T. Ware and Sir Erasmus Wilson be nominated Vice-Presidents in the place of Sir James Paget, elected President, and Mr. Charles Hawkins, resigned, and that Dr. Kempster, Mr. Stamford Feloe, Mr. Brodhurst, Mr. Lowne, jun., Dr. Herbert Davies, and Dr. Russell Reynolds be nominated Directors in the place of the six seniors who retire. Tuesday, the 13th of May, was fixed for the annual general meeting at 5 p.m.

Pass Lists.

Royal College of Physicians of London.—The following candidates, having passed the necessary examinations, were admitted Members on Thursday, April 24th :—

Coutts, John Alfred, M.B. Cambridge, Ladbroke Grove Road, W.
Murray, Hubert Montague, M.B. London, Canonbury, N.
Efringe, John James, M.B. Edinburgh, 36 Bruton Street, W.
Robinson, Luke, M.D. California, 48 Tavistock Square, W.C.
Squire, John Edward, M.D. London, 6 Orchard Street, W.
White, Ernest William, M.B. Lond., Kent Lunatic Asylum.

The following were admitted Licentiates of this College on Thursday, April 24th :—

Alsop, Clement, 5 Upper Chadwell Street, E.C.
Andrews, Alexander Gordon, 44A Colehill Street, S.W.
Bean, Charles Edward, Guy's Hospital, S.E.
Biggs, Charles Edward Forbes, 17 Beaulieu Road, W.
Brodie, Charles Gordon, 12 South Crescent, W.C.
Butler, Gilbert Edward, Westminster Hospital, S.W.
Carnelley, Matthew, Guy's Hospital, S.E.
Carroll, Edward Richard William Charles, Cancer Hospital, S.W.
Claremont, Louis Bennett, Millbrook House, Harrington Sq., N.W.
Clark, Arthur William, Guy's Hospital, S.E.
Clarke, James Macfarlane, Infirmary, Manchester.
Coe, Henry Clark, M.D. Harvard, Detroit, United States.
Colman, Henry, Cumberland House, Kew.
Cook, Augustus Henry, 25 Dunning Road, N.W.
Davis, Slewright Arthur, Llanelli.
Dodd, Arthur Herbert, 2 Petherton Road, N.
Elliott, William Augustine, Windsor.
Griggs, William Alfred, 11 Treasillan Crescent, S.E.
Hayes, James, Leigh, Lancashire.
Hear, Charles Desambler, 4 Campden Hill Gardens, W.
Jones, David Llewellyn, Charing Cross Hospital, W.C.
Kendall, George, 193 Clapham Road, S.E.
Lilly, Alfred Thomas Irvine, 2 Milner Street, S.W.
London, John Edward, Berblow, British Guiana.
Lyon, Thomas Glover, 83 Asylum Road, S.E.
McDonall, Herbert Crichton, 11 Philip Road, S.E.
Mande, Arthur, 5 Bishopwood Road, N.
Milligan, Robert Arthur, 174 Coldharbour Lane, S.E.
Milnes, John George, 67 Upper Tulse Hill, S.W.

Wright, Holland Hodgson, 3 Park Road Villas, S.E.

Royal College of Surgeons of England.—The following candidates, having passed the required examination for the diploma, were admitted Members of the College on Monday, April 21st :—

Andrews, Alex. G., L.R.C.P. Lond.
Bateson, John F., M.B. Ed.
Brown, Osmond Percy, L.S.A.
Burt, Thomas, L.S.A.
Davies, S. A., L.R.C.P. Lond.
Dent, Herbert C., L.S.A.
Evers, Charles John, L.S.A.
Fuller, Arthur, M.B. Ed.
Hardie, R., M.B. Durh.
Hunter, Robert R., M.B. Glas.
James, Henry D., L.S.A.
Marsden, H. H., L.K.Q.C.P.I.
Miller, William Francis, M.D.
Owen, William H., L.K.Q.C.P.I.
Plewmann, Sidney, L.S.A.
Satchell, Charles G., L.S.A.
Starr, William H., L.S.A.

The following were admitted Members on Tuesday, April 22nd :—

Anglin, William, M.D.
Coe, H. C., M.D. Harv. Univ.
Corkhill, J. G. G., L.R.C.P. Ed.
Fall, Edwin A., L.R.C.P. Ed.
Gemmel, Arch. B., L.R.C.P. Ed.
Hale, George Ernest, L.R.C.P. Ed.

The following were admitted Members on Wednesday, April 23rd :—

Anderson, G. E. Caldwell
Barrett, Gilbert Lacy
Bateson, Llewellyn Jones
Braddon, William Leonard
Dixon, J. R. Lucas, L.R.C.P. Ed.
Edwards, William Rice
Forester, Thomas Frederick, L.S.A.
Fletcher, G. W. Henry
Gordon, Frederick William
Gough, John Harley

Harris, John Henry, L.S.A.
Hepworth, Arthur, M.B. Durh.
Lilly, A. T. Irvine, L.R.C.P. Lond.
McVitie, John W., L.R.C.P. Ed.
Nunn, John Robert, L.S.A.
Turner, George, L.R.C.P. Ed.

Hugill, George Frederick, L.S.A.
Morris, E. G. Freeman
Pearson, Hoslop Laird
Pettifer, Edmund Cleaver
Shaw, William Ormerod
Thomas, David
Tomkins, Harding Henbest
Tupholme, John T., L.R.C.P. Ed.
Wells, George Lee
Winton, Alfred do.

The following were admitted Members on Thursday, the 24th :—

Bowes, W. Henry
Blomfield, J. Edward
Brookings, E. Lamley
Chambers, H. William
Comber, A. Wandesford
Garrod, A. Edward
Hutchinson, F. Selby
Jenkins, John
Jones, F. W. Caton
Jones, Thomas

Lamb, Hugh
Molesworth, Robert Everard
Murray, G. A. Everett
Parfitt, E. Browne
Peck, R. Holman
Reeks, John
Turner, A. Jefferis
Williams, J. Traherne
Woolbert, H. Robert
Wright, J. Lister.

The following were admitted Members on Friday, the 25th :—

Anderson, W. Dunlop.
De'Ath, G. Hanby
Fenwick, W. Cecil, L.R.C.P. Edin.
Jacobson, T. Brander
Johnson, Obadiah, L.S.A.
Kent, H. Arthur
Kirkhouse, George, L.S.A.
McDonall, H. C., L.R.C.P. Lond.

Milnes, J. George, L.R.C.P. Lond.
Morton, Frederick
Plant, Charles, L.R.C.P. Lond.
Slater, Charles
Thompson, Martland
Tyrrell, W. G. B., L.R.C.P.
Wilkinson, C. John, L.S.A.

The following were admitted Members on the 26th :—

Bryceson, Ebenezer, L.S.A.
Clayton, J. T., L.S.A.
Colyer, J. R.
Flach, R. Tanner
Head, E. A. D., L.S.A.
Humphrey, F. R., L.S.A.
Lane, F. Herbert, L.S.A.

Monks, G. Howard, M.D.
Pulkin, B. Gibbs, L.S.A.
Sworn, H. G., L.K.Q.C.P. Irel.
Syme, G. Adlington, M.B.
Urwick, William, L.S.A.
White, J. William, L.K.Q.C.P. Irel.

King and Queen's College of Physicians.—At the April examinations the following candidates obtained the licences in Medicine and Midwifery of the College :—

Medicine.

Drake, Thomas George
Dreaper, George Albert
Keating, Michael Edward
Murphy, Richard

O'Connor, William Edmund
Purdon, Joseph Arthur
Robinson, John
Stoney, Frederick J. W.

Midwifery.

Drake, Thomas George
Dreaper, George Albert
Keating, Michael Edward

McCrath, John E.
Murphy, Richard
Purdon, Joseph Arthur

Frederick J. W. Stoney.

At the same court William J. Smyly was elected a Fellow. At the same meeting the following gentlemen were elected to the Honorary Fellowship of the College :—

Henry W. Acland, C.B., President of the General Medical Council.
Thomas Crawford, Director-General of the Army Medical Department.

St. Andrews University.—The following registered medical practitioners, having passed the required examinations, received the degree of Doctor of Medicine at a graduation ceremony last week :—

Christholm, Kenneth, Manchester.
Clapperton, James, Broughton.
Farrar, Joseph, Morecambe.
Higgs, Thomas, Dudley.
Hollings, Edwin, London.

Lloyd, Samuel, London.
Pathhead, Porteous, Fife.
Smith, W., Eccles, Manchester.
Tomlinson, Edward D., A.M.D.
Wilkinson, Adam, Shaftesbury.

Faculty of Physicians and Surgeons, Glasgow.—At the April sittings of the examiners the following candidates passed the final examination for the licence of the Faculty :—

John C. Aldred, Dore, Sheffield; Frederick H. Davis, Dawley; Wm. Duncan, Larne; James Herron, M.D., London; Edward Hopkins, Glasgow; Thomas McIlroy, M.D., Newtownards; James Miller, London; Wm. S. Pratt, Weedon; Geo. C. Richardson, Glasgow; Thomas Russell, Glasgow; Robert W. Slater, Kirkwall.

The following passed the final examination for the double qualification granted conjointly by the Faculty and by the Royal College of Physicians, Edinburgh :—

Haggarth M. Addison, London; Wm. A. Algie, Glasgow; George B. Buttery, Govan; David P. Gage, Kilwinning; Henry A. Keegel, Ceylon; James McIlwraith, Glasgow; Rhys D. Morgan, Glasgow; Alexander A. Sutton, Glasgow; Edward Thomas, Glasgow; George D. Trevor-Roper, Maidenhead.

Notices to Correspondents.

MR. J. H. (London).—Thanks; we shall be glad to utilise the information sent in an early number.

MR. H. F. (Liverpool).—The subject possesses no special interest to medical men; and with the present demands upon our space for legitimate matter, we are unable to accept it for publication.

MR. ROGER WILLIAMS (Middlesex Hospital).—Our space has been all promised for the next few weeks; when these engagements are fulfilled it will afford us much pleasure to put your paper in type.

MR. LEE (Liverpool).—Your paper, On the Reproduction of the Vitreous, is marked for insertion in our next number.

A THIRD YEAR'S MAN will find Dr. Handael Griffiths' "Text-book of Materia Medica" best suited for his purpose.

A DISPENSARY HACK.—Your letter is unfortunately crowded out at the last moment.

SHELFANGER SPA.

ABOUT two years since we called attention to a new health resort, or to be more exact, to an ancient Roman spring re-discovered, and now rising in importance among the Spas of Great Britain. The resident medical officer of that establishment now sends us the following short note received, during the past few days, from the Marquis of Huntly, to which we are happy to afford space, as evidence of the correctness of our views formerly expressed, and of the valuable therapeutic agent the re-opening of this spring places within the reach of physicians at home:—

April 12th, 1884.

DEAR SIR,—My visit to England has, I am thankful to say, resulted in a remarkable improvement in my health, and I shall always feel indebted for it to the bracing air of Norfolk, the mineral swimming bath, and tonic table water of Shelfanger (near Diss). Any seeking a genial and good class home, will find it at the Shelfanger Spa; and they will further find that it possesses invaluable resources of health and recreation. As a matter of fact, I have in one month gained more than half a stone in weight.

I am, Sir, yours truly,

GORDON-HUNTLY.

A NORTHERN STUDENT.—It would be scarcely considerate to the author of the work to print your letter, although the repetition of the statement in successive editions implies censurable negligence in revision of proof-sheets. Your better course would be to write a private letter to the gentleman in question, calling his attention to the matter, and suggesting the necessary correction in future issues of the book.

DR. COLLINS.—As you narrate it, the case appears to be one of intra-thoracic tumour, most probably aneurismal in character. A sign relied on by Dr. Drummond, of Newcastle-on-Tyne, and said by him to be invariably present, is pain at the angle of the scapula. In several instances his diagnosis has been completely verified, even when the usual certain symptoms have failed to present during life.

FEES FOR INSPECTING LABOURERS' DWELLINGS.

R. B. writes: I (as also the other medical officer of my union) was summoned to attend at the Workhouse to give evidence at an inquiry about labourers' houses. We were also requested to attend at a preliminary inquiry held by the guardians some weeks ago. We attended both. Perhaps you would kindly let us know: (1) Are we entitled to remuneration? (2) If so, how much? (3) How are we to proceed in order to obtain it? (4) What unions may we quote as precedents in making our application?

[1. You are—we believe—entitled to payment by the guardians. Your fees for this evidence would be part of the expenses of the provisional order for the building of the dwellings, and would be paid as such. But, if the provisional order falls through, or if you have made inspections, your claim will be against the guardians. Whether they are or are not liable to pay will be decided within a couple of weeks by the issue of an action which the Irish Medical Association has instituted against the Youghal guardians on behalf of the medical officers of that union. 2. A reasonable fee for attending and giving evidence at the inquiry would be from £1 1s. to £3 3s., according to the detention from business which you suffered, and the distance you had to travel. 3. Your best course is to apply to the guardians for payment and await events. 4. A payment for inspections has been made by the South Dublin Union, which is the only precedent we can quote.—ED.]

DR. WAINWRIGHT.—A pill containing acid. carbol. gr. ss. will probably be found more serviceable than any of the remedies you have been employing. It is a powerful anti-ferment.

G. L. R.—The friends of the patient can prohibit post-mortem examination, which then, even in the absence of any certain cause of death, cannot be performed except under authority of an order issued by the Coroner. Should this official decide that such examination is unnecessary, there is no means of obtaining it legally.

MR. MENDOLA.—You are in error, and can only right yourself by acknowledging it.

DR. DONALDSON.—The Bill has still to pass through all its stages in the House of Commons before it has a chance of becoming law; and even then the Lords' assent to amendments introduced in the Commons will have to be given to it first. We do not prophesy.

MR. H. W. B. (Anerley).—The so-called legislation about which you ask our opinion is a snare. It is kept solely for the purpose of gain by an American adventurer, not a member of the medical profession; and the doctor's name given in the prospectus, is not to be found in the official Register of legally qualified men.

HOSPITAL AMBULANCES AND THE TELEPHONE.

THE following letter, taken from a Liverpool daily, needs no comment:—

SIR.—Our telephone was used this morning to call the Northern Hospital ambulance to this building, and in less than five minutes the waggon arrived, accompanied by a doctor. Such promptness, we think, deserves special mention and public recognition, and we would ask you, therefore, to kindly give this a space in your valued columns.

Drury Buildings, 21 Water Street,
April 23, 1884.

Yours, &c.,

ROBERT CROOKS & CO.

Meetings of the Societies.

THURSDAY, MAY 1ST.

HARVEIAN SOCIETY.—At 8.30 p.m., Casual Clinical Communications.
FRIDAY, MAY 2ND.

ACADEMY OF MEDICINE IN IRELAND (Pathological Section).—Mr. A. H. Benson, Orbital Sarcoma.—Mr. P. S. Abraham, Scapulo-humeral Dislocation in the Horse.—Dr. Purser, Malignant Disease of the Pancreas and Lung.—Mr. Story, Rare Tumour of the Orbit.—Dr. E. Hayes, New Microtome.—Mr. Lentaigue, Multiple Diverticula of Large Intestine.—Mr. Thomson, Fracture of the Head of Tibia.—Mr. W. Stoker, Spontaneous Fracture of the Tibia.—Mr. Abraham, Sections from a Case of Exophthalmic Goitre.

SATURDAY, MAY 3RD.

ROYAL INSTITUTION.—At 3 p.m., Mr. Westropp, On Roman Archaeology.

MONDAY, MAY 5TH.

ODONTOLOGICAL SOCIETY OF GREAT BRITAIN.—At 8 p.m., Casual Communications by Messrs. Storor Bennett, E. G. Betts, and J. H. Mummery.—Paper by Mr. E. G. Betts, Observations on the Teeth of certain Rodents.

Vacancies.

Chatham, St. Bartholomew's Hospital.—Assistant House Surgeon. Salary, £100, with board, &c. Endorsed applications to be sent in by May 1.

Coombe Hospital, Dublin.—Assistant Master. Applications to Master, or at Coombe Hospital.

Cheshire County Asylum, Maclefield.—Medical Superintendent. Salary, £500, with furnished house, &c. Applications to Mr. A. C. Procter by May 3.

Royal College of Surgeons, England.—Conservator of the Museum. Salary, £800, with residence. Applications to the Secretary of the College by May 3. (See advt.)

Salop Infirmary, Shrewsbury.—House Surgeon. Salary, £100, with board. Applications to the Board of Directors before May 13.

South Dublin Union, Donnybrook Dispensary.—Apothecary or Pharmaceutical Chemist. Salary, £50. Election, May 6.

South Metropolitan School District.—Resident Medical Officer. Salary, £450, with a residence. Applications to the Clerk to the Managers, Vestry Hall, Walworth, S.E., before May 6.

West Norfolk Hospital, Lynn.—House Surgeon and Secretary. Salary, £100, with board. Applications to the Secretary before May 9.

Appointments.

BARRS, A. G., M.D. Edin., M.R.C.P. Lond., an Assistant Physician to the Leeds General Infirmary.

CLARKE, W. B., M.A., M.B. Oxon., F.R.C.S. Eng., a Surgeon to the West London Hospital.

DONNELLY, T., Medical Officer to Emerald Street Dispensary, North Dublin Union.

HAWKINS, F. H., M.B., Resident Physician to the Royal Infirmary of Edinburgh.

LUCKMAN, E. L., L.R.C.P., M.R.C.S., Surgeon to the Altrincham Hospital and Dispensary.

MACAULAY, S., M.D. Q.U.I., Medical Officer and Public Vaccinator to the Sixth District of the Maidstone Union.

MALCOLM, J. D., M.B., C.M., Surgeon to the Out-patient Department of the Samaritan Free Hospital.

SHIRTLEIFF, E. M., M.R.C.S., Medical Officer for the Ham District of the Kingston Union.

VEALE, H., M.D., Physician to the Colchester General Hospital.

WEISS, H. F., F.R.C.S. Eng., an Assistant Surgeon to the West London Hospital.

Births.

COTTON.—April 25, at 109 Sloane Street, London, S.W., the wife of Holland J. Cotton, M.D., of a son.

MARTIN.—April 19, at 20 Mark Street, Portrush, the wife of J. C. Martin, M.B., of a daughter.

O'DONOVAN.—April 23, at Mount Haigh, Kingstown, the wife of J. O'Donovan, F.R.C.S.I., of a daughter.

Deaths.

DAVIDSON.—April 27, at 44 Leamington Road Villas, W., Thos. Davidson, M.R.C.S., B.A. Oxon., aged 53.

FIELD.—April 21, at the Manor House, Southall, Octavius A. Field, F.R.C.S., late of Sussex Gardens, London, aged 72.

FREEBORN.—April 20, at Oxford, Richard Fernandez Freeborn, M.D., F.R.C.P., M.R.C.S., aged 60.

LOGAN.—March 31, at Suakin, on board H.M.S. *Sphinx*, John Smythe Logan, M.D., R.N., aged 23.

REYNOLDS.—April 9, at Lowestoft, John Swatman Reynolds, L.R.C.P., &c., aged 34.

STONEHAM.—April 16, at his residence, Ilfracombe, Philip Stoneham, M.R.C.S., aged 76.

ON

TUMOR ALBUS. (a)

By PROFESSOR THEODOR BILLROTH,
Vienna.

You see here two children, one of whom has been ill nine months, and for the last three has been confined to bed, from inflammation of the hip-joint. If we take in the clinical picture before us, we see that the child anxiously holds the affected limb in a definite position, namely, flexed, and a little adducted. I can, however, carry out abduction with the leg quite easily without perceiving any crepitation, from which it is probable that the cartilage and synovial membrane are not at present affected, that the disease rather has its seat in the bone itself, and the fact that the child cannot walk is also in favour of this supposition. The cases in which the synovial membrane is affected from the first are characterised by the fact that power of movement ceases earlier and that at the commencement movement is painful. In consequence of the constant position of the leg, shrinking of the ligaments is added; the disease does not lie in the ligamentous apparatus, for primary disease of the accessory ligaments and of the fascia is exceedingly rare. The primary disease lies in the bone, but the question, where is the situation of the original centre of inflammation? cannot be answered with certainty. It may be situated in the acetabulum, in the head of the thigh bone, in the neck, in the trochanter. We may always conclude, however, that a case that in the beginning brings about adduction and flexion must have its seat in the anterior part of the bone, and that an affection is present that so fixes the ligaments that abduction is prevented, and that therefore the ileo-pectineal ligament is especially drawn into sympathy.

In the case of the other child you observe a tolerably considerable swelling of the knee-joint. The disease is

said to have followed a fall. In the course of it an abscess appeared which broke externally. This child holds its knee in a flexed position, and experiences intense pain when I attempt to stretch it; the disease, therefore, probably resides in the joint itself. A yellow tuberculous pus flows from the abscess opening; this character of the pus, however, proves nothing as to the seat of the disease. Is the cartilage destroyed? We should verify this if we felt crepitation on movement, a symptom that shows the contact of two bone surfaces and their rubbing over each other. We feel no crepitation. This negative symptom does not permit us to exclude the hypothesis of destruction of the cartilage, for we must keep before our eyes the possibility that the cartilage is destroyed and replaced by masses of granulations, for in the latter case no crepitation would be perceptible. We should conclude that destruction of bone was present if any deviation of the bone from its normal direction, or any shortening, could be perceived. It is important in the determination of this question to ascertain whether the patients can bear pressure upon the articular surfaces without much pain, and whether they can walk. The child can walk, and it can bear even sudden pressure upon the surfaces of the joint without great pain: therefore, the bone is apparently not attacked, at any rate, not close to the articular surfaces, but perhaps at a short distance from them. Under narcosis I can distinctly cause lateral movement, whence we conclude that the capsule and ligaments are destroyed. We have therefore a case of fungous synovitis before us, or what is also called a *tumor albus*. As I now open the joint in order to remove the fungous mass of granulations, you see the capsule of the joint thickened, so as to resemble a fatty layer; the synovial membrane seen through the mass of granulation also appears considerably thickened, and the whole of the cartilage is covered by granulations. This is the reason why we felt no crepitation. It is a fungous synovitis, which in its spread has gradually destroyed the cartilage, but has not penetrated into the bone itself. As regards the commencement of *tumor albus*, there are two kinds: 1. It may have its origin in the synovial membrane, so that the case will be one of chronic parenchymatous synovitis; and 2. It may proceed from

(a) From the Wiener Allgem. Med. Zeitung.

the bone itself and begin either as diffuse, rarifying osteitis, which is very rarely the case, however, or in consequence of the deposition of tubercle-bacilli (as so-called circumscribed caseous osteitis, as it was formerly called), as tuberculosis with reactive processes around this primary centre. In regard to the synovitis, this is distinguished in its first commencement by reddening and swelling of the synovial membrane, which finally goes on to secretion; the exudation is at first rather muco-fibrinous, but later on becomes more purulent; the synovial membrane becomes thicker, redder, the villi grow and soon become granular in appearance. In this condition they grow on, and soon cover over the whole cartilage, just as pannus grows over the cornea and covers it like a veil, whence this form has been named pannous synovitis. These granular growths, however, shoot out processes into the substance of the cartilage itself, processes which I like best to liken to ivy roots, for the ivy not only twines itself around the foreign body standing near it, but sends down roots into the soil. In this way the cartilage is entirely destroyed by the spreading granulations. When at the same time similar granulations from the bone, or the granulations from the synovial membrane further develop at the margin between the cartilage and the bone, it may happen that the cartilage is completely undermined at certain spots, so that it may often be seen floating like an island between masses of granulations. I was formerly of opinion that the disease was most frequently originated by the processes above described, that it began as chronic synovitis, and subsequently led to caries of the bone by the granular masses penetrating into the bone, when suppuration or caseation took place, or caries developed. As has been shown in recent times, however, pure primary synovitis is a very rare occurrence; it is rather the consequence of another process; it must thus be looked upon as secondary. At one time our attention was only directed to the material we met with after autopeies and amputations; we found a panarthritis, but we could not decide accurately where the affection originated. But after Volkmann had given utterance to the opinion that in this disease we could not resect early enough, people began to resect the heads of joints in great numbers, whereby they gained the opportunity of beholding the disease in its various stages. From the great series of preparations thus obtained it was discovered that the osseous origin was the most frequent. Before this we had found in these cases that yellow caseous masses were present in bone, and the supposition was that these were simply caseations, the outcome of chronic inflammation; that this inflammation might eventuate in granular growths, in suppuration, in caseation, or in pure ossification. According to our present views we must say that the termination in caseation does not exist, but that, on the contrary, this caseation is primary, as in consequence of the immigration of tubercle bacilli a caseous clot is formed, and the clot, partly mechanically, and partly chemically, reacts on its surroundings. In the intestinal canal growths and ulcerations arise after the deposition of tubercle; the like is the case in the larynx. In other organs, in the lymphatic glands, for instance, swelling first takes place, then comes suppuration. In bone hyperæmia most frequently comes on around the tubercular mass, and osteitis, with a tendency to the formation of granulations, which gradually lead to resorption of the bone. We now come to the question, how near does this clot lie to the joint? If it does not lie far off, the cartilage and synovial membrane participate in the process, and thus we have the whole pannous-fungous synovitis as a consequence of the primary deposition of tubercle bacilli. Cannot the original caseous clot become encapsuled? We cannot indeed deny this, but at any rate it happens very rarely. If the tubercle acts only mechanically as a foreign body, then it can become encapsuled, but I do not place much importance on this mechanical action, and it is principally the chemical action that calls forth all the later changes.

NOTES ON THE REPRODUCTION OF THE VITREOUS. (a)

By CHAS. G. LEE, L.R.C.P. Lond., M.R.C.S.,
Assistant Surgeon to the Liverpool Eye and Ear Infirmary.

MR. LEE first remarked that although, owing to the introduction of the ophthalmoscope, any changes that may take place in the interior of the eyeball can be noted and defined with as much ease and precision as though they occurred on the exterior of the body, there yet remained a sufficient number of unsettled questions and unrecognised facts to prove interesting matter for further observation.

His next observation was, that of all the structures that go to form the globe of the eye, the vitreous has hitherto received the least attention, and, in support of this a late paper by Dr. Brailey, published in the last volume of the Guy's Hospital Reports, was quoted as follows:—"The condition of the vitreous body in different diseases appears to be a subject worthy of more consideration than has hitherto been bestowed upon it."

Attention was next drawn to the usual descriptions of the vitreous contained in ordinary text-books, which were summarised thus: "It is said to be a jelly-like fluid, held in suspension by thin filaments, prolongations from its investing capsule, the hyaloid."

Comparison was invited to the above by the following remarks:—Dr. John Alt, of Toronto, in his work entitled "Lectures on the Human Eye in its Normal and Pathological Conditions," published in 1880, denies the existence of this hyaloid membrane, as well as the fibrillæ; all that he has observed is that the jelly-like substance is somewhat denser and tougher at its periphery. The cellular structures (endothelial and epithelial) usually described on the membrana hyaloidea, he is convinced do not exist. The same author, speaking of cells in the vitreous, agrees with and quotes Schwalbe, who declares them to be lymph cells—that is, wandering cells, coming from the membranes surrounding the vitreous. If, then, the vitreous body has neither cells nor blood-vessels of its own, how can it, he asks, suffer from primary inflammation? Moreover, De Wecker, in his "Ocular Therapeutics," states that all cells found in a healthy adult vitreous are various forms of amoeboid cells, which change their appearance. They are all leucocytes, and he further denies the possession to the vitreous humour of any endothelium. It cannot, therefore, he argues, take any part in an inflammatory process.

It might be objected, and at first sight with much apparent cogency, and innumerable facts might be brought forward to substantiate such an argument, that far from being unable to take part in an inflammatory process, the vitreous is most easily irritated. Thus, the proneness of the vitreous to resent the presence of any foreign body in its substance has always been accepted as a surgical axiom, and there is no dearth of examples that, constantly recurring, have served to justify this conclusion—from the couched lens to the finest thread, all alike, with the same results of inflammation. On the other hand, however, we must observe that in all of these experiments the external tunics have, to a greater or less degree, and of necessity, shared in the traumatism.

It was next pointed out that, although it may be impossible for art to introduce a foreign body into the interior of a closed sac without first making an external opening for its admission, yet Nature may be able to accomplish this. The paper proceeded as follows:—Let us suppose that possibly a cisticercus has obtained a passage by means of a blood or lymph-vessel, and then to remain in the vitreous without setting up irritation, until by growth its bulk made it intolerable—we should then be furnished with an argument which would support these observations, that the vitreous itself is an almost inert body. This picture is not all imaginary, for I have myself had an opportunity of observing a patient who

(a) Read before the Liverpool Medical Institution, March 27th.

attended as one of Mr. Richard Williams' out-patients at the Eye and Ear Infirmary, and whose vitreous chamber had become the *habitat* for one of these unbidden guests; and for the time he was under observation, some two or three months, without causing the thinnest cloud or opacity that might indicate to the observer vitreous irritation.

Finally, this slow response of the vitreous to irritation is made more credible from what may be termed its functional inactivity; unlike the iris or retina, it is not constantly in requisition to perform some work which will necessitate loss and reproduction of structure, it has merely to passively permit light rays to traverse its substance, and to mechanically distend the eyeball. Consequently, it requires few or none of those cellular elements whose presence would afford it responsive inflammatory power.

My hope in bringing these observations under your attention is that, as they have suggested to my own mind a solution of at least one process that takes place in the eyeball after a loss of vitreous substance, they may when submitted to you prove equally convincing. The process to which I allude is that which takes place in cases of cataract extraction, complicated with a moderate loss of vitreous substance—cases which, though happily not common, nevertheless do occasionally occur, even when the operative measures have been conducted with the greatest skill and nicety.

The question, then, is—From what source and by what means does that reproduction of substance take place in the contents of the eyeball which we should presume to be an optical necessity, and which within certain limits we know to be a clinical fact, in order to ensure the amount of vision that some of these cases obtain? It might be supposed that this is already a settled question, but such is not the case. Text-books on eye diseases, speaking of this question, are for the most part characterised by an unanimity of vagueness. Thus, they say that "the loss is made up by fluid," or, again, by a "watery fluid," or, yet again, by a "serous fluid." The necessity for providing a source for this fluid does not appear to have occurred to them. Though I have no doubt that the source I am about to suggest as the most probable one may have frequently occurred to others, it has as yet, so far as I know, met with no distinct expression. We have already seen that the vitreous contains neither blood-vessels nor cells of its own—that, in short, it is a substance with but little tendency to molecular change, if we except that of a degenerative or atrophic one (e.g., fluid vitreous). Such being the case, it clearly has no provision for its own reproduction. What increase of bulk that does take place must of necessity be the product of neighbouring structures. These are, on the one hand, the vascular choroid with its proneness to inflammatory reaction, and, on the other, the structures whose normal function is the secretion of the aqueous humour. Is it unreasonable to presume that the aqueous itself replaces the lost vitreous? The lens having been removed, there now exists no barrier to interfere with a free communication between the aqueous chambers and the space lately occupied by the spilt vitreous. That the aqueous appears not ill-fitted as a substitute is evident when I remind you of the close similarity of both its chemical composition and its refractive index; and further, the neutrality, or rather stability, of its chemical composition would seem to ensure its non-irritating qualities.

These analyses were recently published in the *Ophthalmic Review*, and I append for comparison's sake that of serum, this last from Foster's "Physiology":—

	Vitreous. Per cent.	Aqueous. Per cent.	Serum. Per cent.
Albumen ...	0.74	0.082	8 to 9
Other organic matter ...	0.71	0.148	2 to 1
Ash ...	0.71	0.993	
Water ...	98.884	98.777	90
		Vitreous.	Aqueous.
Refractive Index ...	1.339	1.337	

If this be not accepted as the true source, we are necessitated to endow wandering choroidal leucocytes, or exuded serum, with qualities of stability and transparency—properties which are not usually characteristic of such structures. It would prove a matter of some difficulty to instance any conditions in which a morbid exudation is utilised for the fulfilment of a physiological function. We are all familiar with the disastrous effects of choroidal secretions in the vitreous in those cases of neglected myopia where the vision is reduced to almost nothing from the opaqueness of the exudative material.

Although the choroid has been spoken of as a neighbouring structure to the vitreous, we of course recollect that the retina itself intervenes, and this fact makes it more unlikely that the choroid should be the source of re-supply. Any choroidal secretion would have to pass through the retina by osmosis, and at the same time not interfere with its perceptive functions. Whether the retina is capable of permitting this movement through its structures without either functional or structural damage is questionable. That it (the retina) is capable of retaining or damming back, so to speak, to its own detriment fluid accumulations behind it, we all know too well.

These remarks will, I trust, prove sufficient to substantiate my proposition that the uveal tract, or rather those structures whatever they may be whose function is to secrete the aqueous humour, and not the choroidal coat, is the true source of re-supply to a damaged vitreous.

THE TREATMENT OF PHTHISIS PULMONARIS BY ANTISEPTICS. (a)

By C. NELSON GWYNNE, B.A., M.B.,
Honorary Medical Officer Sheffield Children's Hospital.

MR. PRESIDENT AND GENTLEMEN,—The remarks I have to make in this communication are less to give than to extract opinions and information. The subject, as you all must allow, is an important one; and though not new, yet, owing to the investigations and researches of the last two years, it has assumed a still further importance, as having at length gained some scientific standpoint to recommend it to thoughtful practitioners. In fact, to a large extent the treatment of phthisis pulmonaris by antiseptics is a corollary to the newly-arrived-at theory of the causation of that disease.

In treating of the use of antiseptics in this relation, I must be pardoned if I wander occasionally into some remarks on the micro-organic origin of the disease. In remote and minute pathological researches I fear the general practitioner must feel himself to a great extent out in the cold, and not likely to contribute much. Leisure and opportunity are wanting, and most of all adequate training; but in criticising new pathological and etiological theories and speculations he has a most important part to fill, and one eminently suited to his genius. How far these theories correspond to clinical features and the general history of disease he can from his large clinical experience afford no mean or unimportant elements to the discussion. His thoroughly practical knowledge is indeed not to be despised in an age when theoretical speculations are inclined occasionally to run mad.

For the last nine months I have treated a number of cases of phthisis (in all about a dozen) by antiseptic inhalations. I did not start with any favourable impressions of the probable value of the treatment; I was rather inclined to believe that, allowing Koch's experiments to have been conducted exhaustively, and allowing to the tubercle-bacillus the honour of being the prime cause of tubercular consumption; still I was, I say, inclined to believe that the afore-mentioned

(a) Read before the Sheffield Medico-Chirurgical Society on Feb. 21, 1884.

bacillus was reasonably safe from any fatal danger that could approach it through the medium of the strongest antiseptic or germicide inhalations that could be employed; and I may say that on this point I am very much of the same opinion still; but as a valuable adjunct to the general treatment I am convinced of their very great importance. The almost unanimous opinion regarding their value by the patients themselves confirms me in my opinion. That they "ease the breathing," "assist up the phlegm," "lessen the phlegm," are the expressions I daily hear regarding them; and the benefit derived is so great that many of my patients make use of the respirator-inhalers much more frequently than I have recommended, and after many months of experience still are as firmly convinced as ever of the benefit they receive from their use. The principal ingredients I have used are carbolic acid, creosote, thymol iodine, and turpentine; and all these my patients have had no difficulty in using, nor had any dislike to, with the exception of the iodine. The etherialised tincture is, I find, well recommended; but I could never induce my patients to make use of it for any length of time, nor did they speak favourably of the benefit derived from it.

At the present time I am treating four phthisical patients with antiseptic inhalations, and in all with markedly favourable results. It will be important for you to know in each case the condition of the lungs when inhalation of antiseptics was commenced, the length of time the inhalations have been in use, and the results attributable to their use.

NO. 1.—Mrs. H., *æt* 31; three children, youngest two years old; no family history of consumption. I made special inquiries on this point and got the entire family history from her mother. For two or three winters she had chronic cough, not by any means severe, and which departed on the approach of warm weather, until last spring, when it did not improve, but continued through the summer. In the autumn she occasionally saw some little blood in the expectoration. On the 1st of September, during a fit of coughing, a large quantity of blood was spat up, not much less than five or six ounces. I was called in, and under treatment the bleeding gradually ceased, though the expectoration was tinged for nearly a fortnight afterwards, and after about the same interval she had a return of the hæmoptysis, which yielded sooner to remedies and has not since returned. For nine months she has lost flesh progressively and had severe night sweats. The hæmorrhage proceeded from the right lung and apparently from the middle lobe. The physical signs are some dulness beneath the clavicles, tubular breathing in the same region, and bronchophony well marked on the right side. Now, this patient had abundant expectoration of yellow phlegm mixed with frothy mucus for nine months, and after the hæmoptysis the amount increased till, I should say, six or eight ounces a day was spat up. Her treatment has been generally tonic combined with antiseptic inhalations. The latter she has used without intermission for over four months with this result, that the amount of the phlegm has been reduced to, at most, an ounce a day and sometimes not half that amount; the night sweats have almost ceased; she has gained a little flesh, is able to do her housework, and laryngitis, which complicated her case for a couple of months, has almost disappeared. Now, this patient has ceased for the last month taking medicine, but persists with the inhalations regularly, finding, she says, marked and immediate relief from their use. The formula used in this case was very similar to that of Coghill's, viz., R. Acid carbolic, ʒij.; ol. creosoti, ʒjss.; glycerine, ʒj.; saturated solution of thymol, ʒjss. Occasionally a few drops of chloroform was added to the above. Turpentine was also used, and its effects were most satisfactory.

CASE II.—Wm. Jackson, *æt* 39, worked in the cellars of a brewery; never imbibed freely, but only to a

moderate amount. His father died of consumption, *æt* 47; his grandfather and grandmother lived to be 83 and 84 respectively. He is a muscular, well-built man, about 5 ft. 10 in. in height, and weighing, before he got ill, 12½ stone. About three years and a-half ago he suffered from occasional blood-spitting, and was apt to catch cold and suffer from a cough. The hæmoptysis was only once severe, and I attended him at the time. After that he regained his strength and seemed, for a year, to gain weight as well, as he attained to his maximum weight, viz., 12½ stone. Last summer his cough returned, and he began to lose flesh; his appetite failed him, his breathing became very short, and he complained of extreme debility. The physical signs in this case were not as bad as one would expect from his general appearance, for his legs and arms and face were very much emaciated, and his breathing short. Dry crepitations were audible in both lungs, but were few, and sometimes they quite disappeared; the breathing was inclined to be bronchial but not markedly so, and there was slight degree of dulness over the entire front of both lungs. He complained much of pain and tenderness in the abdomen, and it gave the sensation to the palm of the hand as if it were studded, especially around the umbilicus, with small, hard glandular bodies. Near the navel they were about the size of No. 5 shot, or half the size of a small pea. His temperature varies from 99° to 101°. I cannot say there is any improvement in his condition since the above notes were taken on the 7th December, 1883; but I am sure of this, that the disimprovement has been by no means so rapid, and reference to notes taken of his condition a few days since shows the only change to be slight increased vocal resonance. He finds inhalations of great service, and he invariably has recourse to them whenever his breathing is especially short, and is convinced that they "ease his breathing." Spt. terebinthine and the formula above mentioned were mainly adopted in this case. I find in the notes of this case that twice within the last two months he suffered from facial paralysis which lasted on each occasion about twenty-four hours; the last attack left his mouth slightly drawn to one side for many days after, but as well as I remember it had disappeared the last time I saw him.

CASE III.—Mrs. G., *æt* 29, has had four children in six years, the youngest, only four months old, taking the breast occasionally during the day. No history of phthisis in her family. I first saw her early in December, 1883, her condition then was: Slight dulness on percussion at left apex, some flattening and deficient expansion on that side, expiration prolonged, vocal fremitus increased, breathing coarse, and dry crepitations in the supra-clavicular region. On right side breathing was fairly normal, but dry crepitations could be heard above clavicle. She had night sweats, and a very troublesome cough, had lost flesh, spat up a lumpy dark phlegm, and had a very bad appetite. The treatment has been by inhalation, tonics internally, cod-liver oil. The latter she soon had to give up, and Kepler's extract of malt was substituted for it. At first she used in the inhaler the etheriated tincture of iodine, but she disliked it so much, and seemed to get so little relief from it, that I returned to the same formula as I used in the other cases. I saw her to-day and she told me that she has made progressive improvement during the past three weeks, the night sweats all leaving, her cough is not so hacking, her appetite is improved, and she thinks she has gained in weight. I did my best to induce her to give up nursing, but she does not like doing so, but she does not give the baby so much as formerly.

CASE IV.—Rylett, Wm., *æt* 35, unmarried, Scots guardsman. He is the third of the family affected with pulmonary phthisis. Two of his brothers have already died of that disease, one at the age of 14 years, and the other at the age of 19 years. Up to June 1882

he was strong and healthy, and weighed 12 st. 8 lbs. In the camp at Aldershot he contracted rheumatism from exposure and wet. In the October of that year I first attended him when home on sick leave, and he then seemed to recover rapidly, and no tubercular symptoms were recognised. After his leave was up he went back to service in London, where he commenced again to lose ground. His cough returned and expectoration increased. In June 1883 he returned home on sick leave, and I attended him again. He then weighed 8 st. 5 lbs., had unmistakable evidences of tubercle, and expectorated profusely. From that time up to the present he has been constantly using the respirator-inhaler with results equally satisfactory to himself as to me. His sputum from being as much as half a pint a day has not been for the last two or three months more than a couple of ounces daily. His appetite has improved, and up till quite lately was very good, his tongue being quite clean and natural in its appearance. Unfortunately in other respects he did not make similar improvement, for he continued to lose his strength and flesh in spite of his good appetite, and for the last six weeks he has not left his bed. His temperature has varied from normal to occasionally towards evening 101°. Lately I have been paying him only occasional visits, and about a fortnight ago he drew my attention to his feet being swollen. I desired him to send up a sample of his urine, which I found loaded with albumen. He did not complain of any pain in the back. Since then the dropsy and ascites have increased, and his temperature has been subnormal, registering often a degree below the normal standard. He has little or no cough now, and very little expectoration. His heart does not suggest anything abnormal.

I will give you but one more case, as a counterpoise to the others, where inhalation seemed to exercise no beneficial effect whatever, and where the patient, after using them for about two months at intervals, gave them up altogether. Miss Priscilla K., æt. 26. Well marked family history of phthisis. She was the third of that family that I attended throughout their final illness. She died in December last. I wish in connection with this case to relate the following facts: they have reference to the now much mooted question of the contagiousness of phthisis. Her step-mother, Mrs. K., a woman of fine physique, æt. 52, of kindly disposition and an indefatigable nurse, in the year 1878 nursed her stepson George, æt. 20, during his last fatal illness for one year, and attended on him night and day. He died of kidney disease complicating phthisis. In 1881 she attended her step-daughter Annie, for the fifteen months preceding her death from phthisis, and during all that time occupied the same bed as her patient. In 1882 and 1883 she nursed another step-daughter, Lizzie, for two years, until the time of her death early in the latter year from phthisis. In 1883 she nursed constantly, and slept in the same bed, with another step-daughter, Priscilla, æt. 26, up to the date of her death in 1883. So that she was for five years in almost constant attendance on phthisical patients, and for three years occupied the same bed with patients suffering from that disorder. I may say she has never experienced the slightest harm from this intimate and lengthened intercourse with patients who suffered all of them, from tubercular lung disease.

There are a great number of antiseptic respirators in use, but the one I generally adopt is Dr. Wm. Roberts's. It is of blackened metal, perforated with large holes at the front, shaped to the lips, and half or three-quarters of an inch in depth, with a hinged lid which opens outwards, and allows the introduction of some cotton wool saturated with the material intended to be inhaled. There can be little doubt that impregnating the air of the room with antiseptics will finally take the place of respirator-inhalers, and already many plans have been devised for doing this. If towels saturated in carbolic acid are hung in a room, it has been found that after a

few hours nearly all the carbolic acid will have disappeared from the towels, and will have been taken up by the air of the chamber. Of all the antiseptics, creosote perhaps holds the highest place for this purpose. There are well authenticated cases recorded of phthisical cases having quite recovered by engaging in the manufacture of this article.

The next question to consider is in what way antiseptics act. To call them germicides is manifestly a misnomer, for it is difficult to suppose that the tubercle bacillus could be killed by the necessarily weak antiseptics that are employed, when we consider the well-recognised vitality of these organisms. The answer seems to be that as many surgeons attain as good results in the treatment of injuries by scrupulous attention to cleanliness, as others who use the strong carbolic spray and the other paraphernalia of Listerism, so in the treatment of tuberculous ulcers in the lungs, the constant inhalation of purified air tends to promote healthy action and to lessen the destructive vitality of tuberculous organisms. We know the beneficial effects of the cold pure air of Davos, and how Iceland, with all its damp and cold, enjoys a complete immunity from phthisis, probably owing to the strong impregnation of the air there with sulphur.

The treatment of phthisis with antiseptics has no doubt gained great impetus from the discoveries of Koch, but it does not altogether stand or fall by the fate of those discoveries, for long before Koch's discoveries were heard of, many physicians believed in the beneficial effect of inhalations of such substances as tar, carbolic acid, &c. I cannot myself help feeling sceptical about the deductions drawn from Koch's experiments. I believe that heredity operates far more in the production of tubercular lung disease than is supposed. We all know how slow patients are to admit a family delicacy, and how often they consider that if their parents lived to an old age, there could be no family tendency to consumption, quite forgetting that a generation is frequently passed over. I feel that the answer to the question, how far are the micro-organisms the cause of the disease, is still *sub judice*. It is not enough to prove that they are invariably present, nor even when isolated and introduced into another animal of the same species that the same particular disease is produced; for may it not be that quite innocuous organisms when for a lengthened period brought in contact with diseased structures, may themselves become so modified as to produce the disease when introduced into another animal. In this sense they would occupy but a secondary position, and what we hear spoken of as the "suitable soil" would have to be ploughed up by indefatigable experimentalists in search of the true cause.

Clinical Records.

CASHEL UNION HOSPITAL.

Three Cases of Strangulated Hernia.

Under the Care of Dr. LAFFAN.

W. C., labourer, æt. 57, was admitted 20th February, 1879, for strangulated left inguinal hernia. There was an undescended testis on that side. The hernia was reduced on same day by taxis. The feature of interest in the case is that vomiting of a fecal character, which was present before the operation, continued with no perceptible abatement for three days afterwards. This was so marked that I asked him to allow me to cut down on the ring, but he refused. The fourth day the bowels acted, and though vomiting recommenced—the expelled matters not being this time fecal, and some sharp abdominal pain set in, indicating some peritonitis, all the symptoms disappeared under treatment, and the patient was discharged cured on the 3rd of April. This was one of those cases where inflammation produces sym-

ptoms similar to those of continued strangulation, and where, owing to difficulty of accurate diagnosis, operation is the more prudent course, though sometimes it may turn out to be performed in error. Probably the next batch of cases in my wards with similar symptoms would all turn out to be instances of internal strangulation.

Case II.—J. H., servant, *æt.* 40, was admitted in June, 1877, for an inguinal swelling which he was told was an hydrocele and irreducible hernia. The swelling was most tense. There was fixed pain at the ring, together with vomiting and a general feverish state. There was a previous history of hernia, which was from time to time irreducible. Strangulated hernia was diagnosed, and taxis having failed, I emptied the sac with a fine aspirator needle, after which the gut was easily returned. Sharp pain attacked the patient for some days in the neighbourhood of the ring and over the abdomen. There was also vomiting of so doubtful a nature that I was afraid I should be called on to cut down on the sac. On the third day, however, the vomiting abated, and from that progress was uninterrupted. The feature of interest in this case is the important service rendered by tapping and the subsequent doubtful symptoms.

Case III.—M. H., a woman, *æt.* 50, wife of a small farmer. I was called to see this case in April last by my friend Dr. Jackman, of Thurles. The rupture was a left femoral one. Taxis had been tried in vain, and symptoms of exhaustion were setting in. The usual cutting operation was performed, and the sac was opened. When this, however, was reached, the gut was found to be in a state so nearly approaching that of gangrene that we declined to divide all the adhesions. A slight notch was made in the inner border of the ring, but several adhesions which tied the gut to the bottom of the sac were left undivided. Nor did we venture on dividing some deep seated adhesions within the ring. Furthermore, distinctly faecal matter oozed out at the back of the wound, seemingly having descended from some opening in the gut within the ring. So impressed was I with its faecal nature that I handed some of it on the point of the knife to Dr. Jackman as determining evidence in favour of partial division of the constricting bands. Poultrices were applied and opiates were administered. Within forty-eight hours the bowels acted, and the patient recovered to our no small surprise. One or two somewhat like have been recorded. I could not ascertain that any portion of the bowel was discharged per anum.

ERRATUM.—LIVERPOOL FEVER HOSPITAL.—In our last issue we published a "Case of Empyema complicating Post-Scarlatinal Nephritis," by Robert S. Aitken. The case was under the care of Dr. Robert S. Archer, who was from home when proof was sent him, and who returned it too late for the correction to be made in our last issue.

France.

[FROM OUR SPECIAL CORRESPONDENT.]

PHOSPHATE OF LIME IN RACHITIS, ETC.—So far back as 1869 Dussart established the fact in a valuable paper on "Medical Inanition" (*Arch. Gen. de Med. et de Chir.*), that the presence of phosphate of lime is necessary in the transformation of the albumen of aliments into cells and tissues; that the vitality and heat in animals are in proportion to the amount of calcareous phosphate they possess, and that when deficient of it the tissues absorb from the skeleton the phosphate of lime which is indispensable to their existence, and draw from the fatty tissues the hydro-carbonic elements when these are deficient in food. The conclusion to be drawn from these facts is that calcareous phosphates are indispensable to animal life. If, then, from whatever cause, a waste occurs, disorders will follow, and restoration becomes urgent. Many years ago Piorry recommended phosphate of lime in pregnancy, caries, rachitis, osteomalacia, pneumo-phymatosis, &c., to assist the cretaceous transformation of the tubercles. It can be given with

benefit to young children during dentition, in the form of lacto-phosphate or of chloridic-phosphate, in doses of from one and a-half to fifteen and a-half grains. Moris recommends it for wet-nurses in poor and populous towns to prevent caecochymia and rachitis in infants. Goesselin and Milne Edwards (*Comptes Rendus Acad. des Sc.*, 1856) have, by experimentation and clinical observations, shown its value in treatment of fractures of the bones to be indispensable. Limbs broken in dogs of the same age and weight were put under the same régime, only phosphate of lime was mixed with the food of a number, in which cases the fracture invariably healed more speedily than in the others. In the former cases, when the animals were destroyed the ossification was seen to be far advanced, while in the latter but a very slight development was observed. Milk contains a large proportion of phosphate of lime. It thus follows that if a child be deprived of it rachitis may be the result, especially if there is a predisposition to that disease. The phosphate of lime and milk are clearly indicated as a remedy in such a case. By the use of them Blace and Riant have obtained excellent results in similar circumstances. The usual treatment of scrofula and Pott's disease is a good nourishing diet, exercise, sea and iron baths, quinine, and cod-liver oil; but phosphate of lime combined with the iodides (?) will be found an invaluable auxiliary in those complaints. It is thus very useful in phthisis in which it may assist in the cretaceous transformation of the tubercles, and will counteract defective nutrition and an excessive elimination in the urine of the phosphate of lime of the system. It will also act against abnormal sweating and intestinal secretions. We may add that in virtue of the phosphorus it contains phosphate of lime will tend to strengthen the nervous system.

At the Société de Chirurgie M. Monod presented the anatomical specimen of a monster which he classified under the title of pseudo-encephalus, in which the brain was replaced by a vascular tumour with almost complete absence of nerve fibres. The vertebral canal was split in its whole length to the lumbar region, and between the bones of the head could be seen the vascular mass which seemed to fill the whole cavity. The mother was a strong country woman, thirty years of age, married for six years, and already has had two children. In this her third accouchement everything went on normally until the seventh month, when from some unknown or apparent reason she was seized with pain, and in a few hours afterwards gave birth to the monster in question. A fact worthy of note is that she avers having felt the child stirring up to the last moment, consequently refuting the opinion of those who maintain the incompatibility of life with the absence of nerve centres.

DENTAL EDUCATION IN DUBLIN.

We understand that, after an official inspection, the Council of the Irish College of Surgeons has resolved to recognise, as qualifying for its dental diploma, the course of instruction given in the Dental Hospital of Ireland in York Street, Dublin. The arrangements for teaching reported to the Council by the inspecting deputation are very perfect, and their opinion was strongly expressed that the instruction was given by the staff in all respects with earnestness and in good faith. The departments comprise—

- a. Lecture room, with museum, which is also used for extraction operations.
- b. Operating room for special cases, such as filling, scaling, impression taking, regulation, &c.

c. Rough mechanical workshop.

d. Mechanical and metallurgical laboratory.

The museum of the hospital comprises preparations of jaws at different ages, which are used for impressing on the student many of the important anatomical facts connected with the regulation of teeth and countless other practical matters connected with his clinical studies, comprises also preparations of the fifth pair of nerves and of the arterial supply to the face and buccal cavity, also numerous casts of cleft palate, deformities, supernumerary teeth, supplemental teeth, teeth mercurial and teeth syphilitic.

The extraction room is furnished with suitable operating chairs, hot and cold water, extraction instruments, remedies for arresting hæmorrhage, also with apparatus for administering nitrous oxide alone, nitrous oxide and ether alone. The student has here every opportunity of learning this important branch of his work. The operating room for special cases is similarly fitted up with water supply and all suitable apparatus and plant. As soon as the student can be trusted with an easy operation he is given an easy case and closely watched and instructed, so that he can do no harm, and gradually he is led on from this by imperceptible stages till he can be trusted to perform, under supervision, difficult fillings. All known appliances for operating are here demonstrated and used, and the staff of the hospital take a pride in thinking that no student will leave the hospital without having been instructed in the use of all instruments, new and old, all appliances, and all filling materials. The mechanical and metallurgical laboratory has been fitted up with a superabundant stock of plant for working in the metallic, mineral, and vegetable substances used in artificial dental work. Ten separate benches are fitted up, each with locked drawers, where the student keeps his tools, and works at the mechanical case he is given under instruction. Apparatus for the melting of gold, rolling gold, casting of metallic dies and counterdies, furnace for making porcelain, and continuous gum work, lathe for grinding down and polishing artificial teeth, apparatus for the hardening of vulcanite, the cooling of celluloid, in a word, all the tools and plant of a workshop capable of doing any and every known artificial dental work, are to be found in this department.

We notice the official recognition of the Dublin Dental Hospital with much satisfaction, it being the second step taken by the Council of the College to encourage the establishment of an honest school of dental surgery in Ireland as a preliminary, let us hope, to the issue of an honest diploma which may be held by a respectable dental surgeon. We do not entertain the least suspicion that the staff of the Dental Hospital will accept the patronage of uneducated chemists' boys, hair-dressers, and tobacconists, as the College has done, and without doubt the example of honest and earnest instruction shown by the hospital must sooner or later purify out of existence the present sale of dental diplomas to persons such as those who have taken the L.D.S.R.C.S.I. *sine curriculo*.

Department of Lunacy.

ASYLUM REPORTS.

No precise standard of asylum report can be raised by which to determine the relative merits or practical value of each. Every superintendent sets up an ideal of his own, so that taken *en masse*, we have to wade through a heterogeneous collection, presenting diversities in accordance with individual conceptions of the ideal, or regulated by local circumstances. To generalise on any comprehensive scale

becomes well nigh impossible, and the scientific resultant is necessarily minimised. Many contain the statistical tables of the Medico-Psychological Association, and in this respect exhibit uniformity; but statistics can be garbled, and require careful sifting by the light of local experience, otherwise they must be swallowed with a grain of salt. In dealing with the reports sent us from time to time, only those topics which have been made matter of common observation and remark will be adverted to, in order to favour comparison and promote a useful end.

1ST—CUMBERLAND AND WESTMORELAND.

Dr. Campbell considers that about 10 per cent. of his lunatic population might be suitably treated in workhouses and disposed of as follows:—7 per cent. in special wards with an attendant, 1·2 per cent. in infirmary wards with an attendant, and 1·8 per cent. in ordinary workhouse wards. Dr. Campbell would like to see the scope of the lunacy acts broadened, so as to meet the case of engorged and increasing extension of asylums. The asylum is doing beneficial work in receiving patients from the district at a very low rate of board, *i.e.*, sufficient to cover actual expense of board and lodging. County asylums are so much handicapped by overcrowding, that this possible function of theirs is kept in abeyance, pauperism is stimulated and self-respect and self-reliance are consequently crushed out. Every page of the report bears token of prosperity, and the wise and enlightened views of the Committee of Visitors, and medical superintendent deserved recommendation.

2ND—DERBYSHIRE COUNTY.

Dr. Lindsay is in the turmoil of over-crowding, and sees no immediate outlet possible for this state of affairs. His experience coincides with the observations of Dr. Saunders, of the Devon County Asylum, who prepared a return showing that, in about twenty-six out of thirty-two asylums which have had experience of the removal of the chronic harmless insane to workhouses, the results have not been satisfactory. The conflict of the various authorities implicated in the matter is deplorable. Dr. Lindsay refers with approval to the harmonious co-operation of the Guardians and asylum authorities with respect to workhouse treatment and boarding out in the county of Sussex, and follows out the argument by stating that "the present system and state of the laws rather tend to increase the difficulties of dealing satisfactorily with the insane poor of a district, for the various controlling authorities, often conflicting, render it extremely difficult, if not utterly impossible, to carry out what science and modern progress indicate as the best to be done in the interests of the insane poor, as well as the ratepayers." Dr. Lindsay believes that the only solution of this serious problem will be found to be fresh legislation, which shall place under one controlling authority in a county or district, the pauper lunacy of all shades and degrees. The report is a long one and deals with other subjects which we are constrained to pass unnoticed.

3RD—BARNWOOD HOUSE.

The report of the Committee, Commissioners, and Medical Superintendent record for 1883 an uneventful history, a careful, judicious and, at the same time, liberal management, financial prosperity, and a helping hand held out to the indigent insane of the better classes. There is a temptation to pile on more building, as the demand for accommodation is in excess of the supply, but it is to be hoped that the Commissioners' voice will be heard, and that

no enlargement will be proceeded with which is likely to destroy materially the present homelike and sociable character of the hospital. Dr. Needham is to be congratulated on the success which attends his management.

THE NEW CODE AND OVER-PRESSURE IN ELEMENTARY SCHOOLS.

THE battle of the educationists still appears to rage fiercely, and the non-combatants who in any degree are interested will be scarcely able to discriminate the good points from the bad, so mixed up and multiplied have the issues recently become. The pamphlet presently under review is published at the instance of the National Union of Elementary Teachers, and condenses many salient features of the controversy into very small bulk. But it is far from our purpose to enter into even a cursory consideration of this interminable question. We would merely refer with approval to the proposition of Dr. Farquharson, M. P., that schools should be submitted to regular medical inspection. Such a duty he proposes to saddle on medical officers of health, and he puts forward his reasons with cogency and ability. Dr. Farquharson thinks that no one would attempt to argue against the theoretical advantages of regular school inspection by properly qualified medical men, but he anticipates practical difficulties, the crude solution of which has been already stated. There is a two-fold advantage obvious here; it will create a strong moral support for teachers, and at the same time ensure that due weight will be given to hygienic questions, whether applying to individual scholars or to the school as a whole. Dr. Farquharson has laid down very practical lines on which to run such an innovation, and we can commend his words to the serious consideration of the community at large.

PRIVATE LUNATIC ASYLUMS (IRELAND) BILL.

THIS Bill is backed by Messrs. Corbet, Blake, Dillwyn, Dawson, and Power. Its aim is to repeal the Act 5 and 6 Vict., cap. 123, which provides for the reception of insane persons in "licensed houses kept by any persons for private gain;" and instead it proposes that asylums for pay-patients be provided by order of the Lord-Lieutenant in Council for which money shall be advanced by way of loan from the Church Surplus Fund. It is further provided that the Commissioners of General Council shall be appointed trustees for the purposes of the Act, that the Lord-Lieutenant in Council shall nominate and appoint all officers, frame rules, and prescribe the system of accounts and records for each asylum. In addition the inspection of such asylums, and the forms of admission and discharge have been made the subject of clauses intended to be exhaustive and sufficiently protective of the liberty of the subject.

The Bill is short, evidently the progeny of a single idea, and that idea the hackneyed one of the abuse of private asylums. It is by no means far reaching or far searching, and it does not indicate any very practical acquaintance with asylum administration on the part of the promoters. Great things are done for Ireland nowadays. If this Bill becomes law we fear it will raise a host of grievances, for the question of compensation is resolutely ignored. We hope to see a Bill which has been well considered, and takes a wider grasp, discussed in Parliament before long, but not a Bill which merely nibbles at the private asylum question, and that same very imperfectly. So far as we have been able to gauge it, the feeling in Ireland is that the State should have charge of all lunatics, and, therefore, without implying any want of confidence in private asylums that they ought

to be abolished. But the proposal to do so without compensation is looked upon simply with contemptuous indifference. The moment anyone makes such a proposal *au sérieux* the whole profession will be in arms.

SUPERANNUATION OF ENGLISH POOR-LAW MEDICAL OFFICERS.

THE following address by the English Poor-law Medical Officers' Association to the President and Fellows of the Royal College of Physicians and Surgeons of London, and to the Master and Wardens of the Apothecaries' Society has been sent us for publication:—

GENTLEMEN,—We have been deputed by the Council of the Poor-law Medical Officers' Association to apply to you under the following circumstances:—

In the year 1870 an Act was passed called the Poor-law Medical Officers' Superannuation Act, whereby it was enacted that on and after a given date Boards of Guardians might at their discretion grant Superannuation allowances to Poor-law Medical Officers who had been in office a certain term of time, or who had reached 60 years of age, or who not being of that age were incapacitated by infirmity from performing their duties with efficiency.

Under the provisions of that Act some of the members of the Poor-law Medical Service have been granted Superannuation allowances, but owing to the fact that the Act is merely permissive, many aged and indigent members of the profession who, after holding office for periods varying from twenty to forty years, have been refused by the Board they have faithfully served, any superannuation allowance whatever. In some instances the refusal has been accompanied by an offer of the workhouse or out-door relief.

Many of these aged and broken down Poor-law Medical Officers have in consequence been compelled to apply to be pensioners of the Medical Benevolent College, or recipients of the bounty of the Medical Benevolent Fund.

We believe that it was the intention of the Legislature on passing the Poor-law Medical Officers' Superannuation Act that all Poor-law Medical Officers who had complied with the conditions contained in the Act should receive superannuation allowance; but as the Act has materially failed in such respect we have to respectfully ask you in your corporate capacity to memorialise the Local Government Board and to petition the House of Commons praying that the Act should be amended so as to render its permissive clause compulsory.

We would respectfully point out that a precedent for such action exists in Ireland, where the Colleges of Physicians and Surgeons have severally memorialised the Local Government Board, Ireland, and the House of Commons, in favour of a Bill having such object in view for the benefit of the Irish Dispensary Medical Officers.

We are, Gentlemen,

Yours obediently,

JOSEPH ROGERS, Chairman.

J. W. BARNES, Hon. Secretary.

Transactions of Societies.

CLINICAL SOCIETY OF LONDON.

FRIDAY, APRIL 28TH.

The President, Sir ANDREW CLARK, Bart., M.D., LL.D., &c., in the chair.

Mr. F. J. GANT on a case of

EPITHELIOMA OF THE TONGUE INVOLVING THE FLOOR OF THE MOUTH, LEFT TONSIL AND SOFT PALATE.—REMOVAL BY THE BUCCAL OPERATION.

In the case to which this paper relates the principal points of importance are—the unusual extent of the disease for which the operation was performed; and that the method by buccal incision offers the only, or the readiest way of removing the tongue and adjoining parts involved, in order to extirpate the whole of the disease, under these exceptional circumstances. The question is also raised as to the desirability of reaching

the tongue through the cheek in all cases. Having related the history of the case, the operation, as performed with the chain-écraseur, is fully described. The above propositions are then considered.

Mr. JESSETT asked if Mr. Gant always preferred the écraseur to scissors in such cases. He considered, himself, that Whitehead's operation afforded sufficient access to the tongue without adding the extensive cheek wound of the buccal method, which, moreover, could still be subsequently made if the case required it. The use of scissors did not entail the extensive slough following employment of the écraseur, and the difficulty of arresting hæmorrhage had been exaggerated, the lingual artery being easily seized on its division.

Sir ANDREW CLARK inquired if Mr. Gant considered there was a causal relation between the decayed molar tooth described in the paper as present in the mouth of the patient, and the existence of the disease. If so, what was its nature?

Mr. GANT replied that he only mentioned the tooth in a relationship of contiguity with the epithelioma, and because the patient had associated it as a cause with the condition of his tongue. Mr. Jessett's criticism had gone to the root of the paper. There were four modes of operating in such cases. That introduced by Paget rendered Whitehead's modification an unnecessary addition to surgery, since if the former was impracticable, the latter possessed no advantages over it to entitle it to be resorted to. The oral operation was attended with the disadvantage that it did not admit of far spreading disease, such, e.g., as that of the tonsil and soft palate being reached in cases where the full extent of injury had not been previously ascertained. It also offered difficulties in the way of controlling hæmorrhage if the loss of blood was at all excessive, and proceeded from arteries situated out of reach. Similar objections could be urged against Nunneley's operations, while Regnoli's method, although attended with lesser risks from bleeding, did not admit of excision of the whole tongue, if found requisite. Syme's method was altogether obsolete; and any case that necessitated the complication of a compound fracture of the lower jaw, in order to reach and remove the disease as in Syme's operation, could not be one for legitimate surgical treatment. None of the objections cited, however, attached to the buccal operation.

Mr. TURNER on a case of

GLUTEAL ANEURISM.

Samuel P., æt. 51, coachman, was admitted into the Seamen's Hospital, Greenwich, on September 17th, 1883. He had been previously under the care of Mr. Roper, of Lewisham, from whom the following history was obtained:—On September 5th the patient was thrown out of a pony carriage, and when seen by Mr. Roper, was found to have a scalp wound exposing bone on the right side of the head, and a contusion of the back, right hip, and buttock. He did well till September 14th, when, without leave, he got up. On getting back into bed he felt something snap in the right buttock. Immediate swelling came on, and when Mr. Roper saw him this swelling had most distinct pulsation. Ice was applied locally, and in two days the pulsation ceased and the tumour became hard and painful. On his admission into the Seamen's Hospital the integuments over the swelling were inflamed, and there were marks of fading bruising extending over the buttock up to the scapula. No pulsation or thrill in the tumour, which measured some eight inches by six. The man had been a hard drinker, probably had had syphilis, and both radial and temporal pulses were atheromatous. There was some slight fever on his admission. This subsided after a few days' rest, and the condition of the integuments became less inflamed. The tumour, however, became larger, and fluctuation marked. At one place the skin, on September 30th, was prominent and thinned, the superficial inflammation returned, and the temperature rose again. On October 9th, it was evident a portion of the skin had lost its vitality, and that the tumour was on the point of bursting. Exploratory puncture with a fine trochar showed that the superficial part of the swelling was solid, and gave rise to a flow of bright arterial blood from the deeper part with no relief to the tension. On October 10th the patient was put under ether, the sac of the aneurism laid open from end to end, and more than 42 ozs. of disintegrating blood clot turned out. An oval aperture about the size of a split pea was found in the gluteal artery just as it

left the pelvis. A carbolised silk ligature was placed on either side of this, and tied. The vessels were diseased. During the operation the rectal lever was used, and but very little blood, except that in the sac of the aneurism, was lost. Previous examination by the rectum showed the swelling was extra-pelvic. The gluteus medius, minimus, and the external rotators of the thigh were exposed at the bottom of the sac. The gluteus maximus was completely destroyed. The wound was plugged with a carbolised sponge, and dressed with carbolic gauze. The man did well for eight days, when tetanus attacked him, and he died exhausted on the eleventh day. By that time the wound was granulating healthily; all the sloughs had separated, and all ligatures had come away. No injury to the gluteal nerve could be detected. At the operation the vessel was completely isolated, and seen perfectly before ligature. No post-mortem examination could be obtained. The diagnosis in this case presented no difficulty, although, but for the history, the swelling at one time might have been mistaken for an abscess. It bore no resemblance to tumour of bone. At first it seemed possible that a natural cure would result, and it was not until the tumour was on the point of bursting that operation was undertaken. As the danger of secondary hæmorrhage is so very great, laying open the sac was delayed as long as possible. The rectal lever proved most efficient and should be superior to an abdominal tourniquet in such cases. Since Mr. Holmes's lectures in 1874 two cases of gluteal aneurism have been recorded—one by Mr. Hussey, of Oxford, in Vol. XIII. "St. Bartholomew's Hospital Reports," in which death occurred from secondary hæmorrhage on the sixteenth day after laying open the sac; and another by Dr. Sands, of New York, in the *American Journal of Medical Science*, April 1881. Examination by the rectum in this case showed the sac to extend into the pelvis, and the internal iliac artery to be diseased. Pressure was made by the hand in the rectum on the common iliac vessels on two occasions for 1½ and 3¼ hours, and caused on each occasion some clotting of blood in the sac. Eventually, however, the aneurism resumed its former condition, and in spite of instrumental pressure the patient was discharged in the same condition as on his admission.

Mr. PICK extolled the rectal lever, which he regarded as a most efficient instrument for controlling hæmorrhage, and thereby robbing the operation for gluteal aneurism of half its horror. With its aid the procedure was much simplified, and after clearing out the clot in the tumour the artery could be readily found and tied. Having witnessed Mr. Turner's operation, he could say with certainty that the gluteal nerve had not been included in the ligature with the artery. He thought it might have been well, however, to divide the artery, leaving two ends, instead of following Mr. Turner's plan. In the case of a punctured wound of the temporal artery in a child, attended with repeated secondary hæmorrhage this mode of dividing had proved very successful in permanently staying the loss of blood.

Mr. HOLMES remarked on the importance of the case, gluteal aneurism being of such rare occurrence. He had never seen a case, and of those he had been able to collect, but few were really cases of such aneurism; they were rather, as a rule, traumatic blood tumours surrounded by a sac. There could be but small hope of curing a case in which a wounded vessel existed without a sac, the formation of which constituted the first step towards recovery. Operation afforded the only chance in Mr. Turner's case, and the success to be obtained in such instances depended on many different circumstances, such as the condition of the vessels, this being very unfavourable in the case under discussion, constitutional state, &c., &c. Division of the artery would have been of very doubtful advantage, as even this proceeding would not have afforded protection against secondary hæmorrhage. The principle of arresting bleeding from a punctured artery by completely dividing the vessel, was formerly recognised on the practice of bleeding from the temporal, the artery having been first opened by a puncture, and when sufficient blood had been drawn, its flow was at once arrested by cutting the vessel right through. The position of the arterial wound with respect to the pelvis, whether in or outside, that is, had been rendered easy of detection, by introduction of the mode of rectal exploration with the entire hand. If intra-pelvic, then it would be rash to lay open the tumour, as ligation of the common or internal iliac would be needed in such a case. The rectal lever was by far the most efficient means at hand for controlling bleeding in these cases, and how grave the

danger attending the opening of a gluteal tumour might be, could be appreciated from Bell's account of the operation. It was to be regretted that no post-mortem examination of the body had been made, although it was clear that the gluteal nerve had not been ligatured. It must, however, have been much irritated, and so conducted to the resulting tetanus. Many so-called gluteal aneurisms were not related to the gluteal artery at all; specimens existed in the museum of the College of Surgeons, in which the pudic artery, and others, in which branches of the gluteal were involved. In all, however, it was vitally important to restrain the bleeding point, and in this connection, it should be remembered that Lister's tourniquet was not only very apt to slip, but necessitated an amount of pressure of which the symptoms were almost as bad as those following hæmorrhage.

Mr. H. MORRIS thought it was quite unnecessary to consider the gluteal nerve in relation to the tetanus, because numerous other nerves, including the sciatic, must have been subjected to tension and damage. It might become a question why Mr. Turner had so long delayed to operate. There seemed to be general hesitation to resort to interference in such cases, however, and, especially when carotid aneurism was in question.

Mr. TURNER admitted that it might have been advisable to divide the gluteal artery; but he reminded Mr. Pick that the suggestion of the latter to that effect had been made during their return to town *after* the operation. Published cases of gluteal aneurism were those in which a wound or stab had caused the injury, and in such, immediate opening of the tumour was desirable. In his own case, operation was deferred because on admission of the patient spontaneous cure seemed to be in progress. Later on, the aneurism seemed to be undergoing extension, and then operation was delayed only long enough to permit of remission of feverish symptoms.

Mr. ARBUTHNOT LANE read an account of a case of

EXTENSIVE THROMBOSIS FOLLOWING FRACTURE OF BOTH BONES OF THE FOREARM.

On the 9th November of last year the patient fell heavily on her left side down some steps, breaking both bones of the forearm, the ulna at its centre, and the radius at the junction of the middle with the lower third. There was much displacement of the radial fragments. The shoulder and arm were also much bruised. The swelling subsided within a few days, and the arm progressed very favourably till the 29th November, when sub-inflammatory oedema of forearm set in and extended into the upper arm. It was accompanied with much pain and tenderness, especially along the front of the forearm and course of the brachial vessels. It almost completely subsided, only to reappear more extensively on December 21st, accompanied by still greater pain. It again subsided, and again returned on January 5th. This time it extended up to the shoulder. She had now great pain in the neck and above and below the clavicle. By the 15th January the left side of the chest, neck, and face were much swollen and were extremely painful. There was also severe headache in the left side of the head. She was very prostrate. Dr. Carrington, who saw the case with him at this time, also felt no doubt that the thrombosis had extended along the subclavian to the innominate and internal jugular veins, and a rapidly fatal termination was feared. However, the swelling slowly subsided from the left side of the face, then from the neck, and then from the side and upper arm, and by the 6th February it was limited to the forearm and lower third of the upper arm. On the 9th February she had a recurrence of the swelling which extended to the side and neck, with pain and tenderness. This subsided, so that she was able to get about and commence to use her hand and arm which was progressing very favourably. The radius has, however, not united by bone. On April 1st, without any apparent cause, a rapid and complete recurrence of the swelling took place, not, however, being accompanied by the same very great pain, nor with such severe headache. The left side of the face was much swollen, as was the neck and side. This swelling of the face and neck subsided, leaving by the 10th April the left side and back of the chest about two inches larger than the right, and the left arm a good deal swollen, so much so that she could not use it. There was a firm resistance along the left internal jugular. She continues to improve steadily.

Mr. HOLMES said the late Mr. Callender had pointed out the influence exerted on union of bones by injury to large

veins, the blocking of which might even completely prevent such union. Was union ultimately obtained in Mr. Lane's case?

Mr. LANE replied in the negative, and that it was likely such union never would occur.

DISLOCATION OF THE ELBOW BACKWARDS, WITH FRACTURE OF THE CORONOID PROCESS.

A paper with this title, by Mr. H. A. Lediard, of Carlisle, of which the following is an abstract, was read by Mr. R. J. Godlee:—A young fisherman, æt. 28, fell whilst wrestling, his hands touching the ground in the prone position with the arms extended. He heard a distinct snap. After undergoing a course of unsuccessful manipulation by a bone-setter, he was admitted into the Cumberland Infirmary with displacement of both bones of the forearm backwards, causing almost complete inability to produce either flexion, pronation, or supination. Concomitant fracture of the coronoid process being diagnosed, excision of the joint was performed. The patient was well in a month, the movements of the new joint progressing satisfactorily. The specimen (which was exhibited) showed that a considerable piece had been broken off the coronoid process, the fractured surface having eroded and polished the posterior surface of the trochlea. The head of the radius lay behind the capitellum, the sigmoid cavity in its centre being filled up with a semi-fibrous mass, which would have formed an insuperable obstacle to the reduction of the dislocation. A small chip of bone was found adherent to the capitellar surface of the humerus, possibly a part of the fractured process. The opinions of most authors agree in regarding this injury as extremely rare. In two cases, however, in which dislocation of the radius and ulna recurred after reduction, Mr. Lediard had been able to diagnose fracture of the coronoid process, in addition to the displacement.

Mr. GODLEE considered it was doubtful if the point of bone described as the coronoid really was that process.

Mr. HOLMES said surgeons varied in opinion respecting the rarity of the accident involving fracture of the coronoid in backward dislocation of elbow. He mentioned the well-known specimen in St. George's Hospital museum, obtained from a boy, who fell from a height and dislocated both elbows, fracturing each coronoid at the same time. Another case, under his own care, was that of a man suffering from dislocation of the radius and ulna. The limb was flexed, and the dislocation easily reduced, but would not remain so. Crepitus was distinct, and there was no doubt that fracture of the coronoid had occurred also. He quite agreed with Dr. Lediard's explanation of the case read.

Mr. GANT thought the injury a very rare one, and that the case was an admirable one for excision. He knew of no apparatus capable of maintaining reduction in such cases.

Mr. MORRIS suggested that when the brachialis anticus muscle drew up a fractured coronoid process, evidence of the fact would be obtained in the presence of a hard lump on the upper arm. At the same time, too, fracture must have occurred very low down, owing to the insertion of the muscle being at the very base of the process. The rarity of such accidents might be explained on the ground of their being difficult to diagnose. He had seen but one himself of this nature.

ACADEMY OF MEDICINE IN IRELAND.

SUB-SECTION OF ANATOMY AND PHYSIOLOGY.

A MEETING of the Sub-Section of Anatomy and Physiology was held at the Royal College of Surgeons, Prof. J. MALLER PURSER, President, in the Chair.

Mr. J. FREEMAN KNOTT, hon. sec., read the minutes of the previous meeting, which were confirmed.

MICRO-PHOTOGRAPHY.

Dr. SCOTT exhibited specimens of micro-photography, and the camera by which they were produced. Seeing Dr. Dickenson's instrument at the previous meeting, he thought it was a very good one, but too expensive, and he devised the camera himself by which the photographs exhibited were produced. The instrument was so simple and cheap that anybody possessed of a penknife and the lid of a cigar box could, with a little mechanical skill, make one for himself. The photographs proved what the instrument could accomplish. Sections of the gastric glands and duodenum were sufficiently sharp as to bear enlargement to diagram

size for a lecture theatre. Practically the working of the camera was on the same principle as that shown by Dr. Dickenson. In Dr. Dickenson's camera there was an arrangement for sliding the ground glass in and out of its place. In this one, however, the sensitive plate was simply laid in the place previously occupied by the ground glass. The removal of the camera from the microscope proved not to alter the focus. In this way, after an exposure of two minutes, he took pictures.

The PRESIDENT asked whether there was any risk of the light getting in at the side, and whether the pictures exhibited were taken by daylight?

Dr. SCOTT—No; but by a 4-inch paraffin lamp, not even a duplex. I have not found the slightest difficulty about the admission of light.

Mr. ABRAHAM inquired what kind of stains Dr. Scott found most suitable?

Dr. SCOTT, in replying, said, speaking from a photographic point of view, he thought red stains were the best, such as carmine, which brought the stained portions out perfectly black and sharp. A blue stain or even a colourless object, if sharp, like a diatom, carefully treated came out well. If a section was very thin, it had better be stained with some red dye, but he had photographed a colourless diatom by the camera sufficiently sharp to bear enlargement up to 10,000 diameters. One of the enlargements exhibited was 1,500 diameters and yet sufficiently sharp for a lecture theatre.

Mr. ABRAHAM said the photographs were very sharp, so that the method of producing them was a very good one, and therefore of great advantage to pathological and microscopical observers.

NOTE ON AN EPIPHYSIAL LAMINA ON THE BASI-OCIPITAL BONE OF AN AMERICAN TAPIR.

Mr. P. S. ABRAHAM, in his communication, stated that on examining the skull of a young American tapir which died last year in the Zoological Gardens in Phoenix Park, a well-defined sutural line, situated near the anterior border of the basi-occipital bone (bordering upon the junction with the sphenoidal bone) on the superior surface was observed. On applying the point of a knife, a thin lamina of bone was prised up. In position and appearance it bore a strong resemblance to an epiphysial ossification, and reminded him of the ring-like epiphysis often connected with the vertebral centre. It is so closely oppressed, and evidently beneath the level of the periosteum, that he did not think it to be an accidental ossification of the dura mater; it rather seemed to be of an epiphysial nature. In order to obtain the opinion of the members of the Anatomical Section on the point, he had brought forward the specimen. Seeing that most anatomists now admit the basi-occipital to be serially homologous with the vertebral centre, the observation might be of some interest. Epiphyses ossify late, and may become ankylosed soon. It was possible that this particular one had not been noticed, as not having been looked for in a complete series of the young skulls of various animals. Up to the present he had not succeeded in finding a second example.

Mr. J. FREEMAN KNOTT said the point was a very interesting one to anatomists. The last book he had been reading on the subject was Hanover's, on the Prunorhial Cartilage. This author made two vertebral segments of the basilar portion of the skull, and said that the junction of the vertebral portion was found at the sphenoid-occipital suture. According to this view, Mr. Abraham's epiphysis would correspond to the superior accessory disc of the upper segment.

THE ACCESSORY NERVE OF WILLIS.

Mr. J. FREEMAN KNOTT, in his communication, gave a classified list of the chief varieties in the origin and course of the spinal accessory nerve that had fallen under his observation, and compared them with the published records of other observers. This was followed by a historical sketch of the progress of our knowledge of the functions of this nerve, in which special attention was directed to its influence on the cardiac movements.

The PRESIDENT remarked that François-Franck had experimented on different animals, and believed that in most cases it was utterly impossible to tear out the spinal accessory without injuring the roots of the pneumogastric to such an extent as to spoil the experiment. François-Franck

believed that most of the discrepancies reported were due to this cause.

The Sub-Section then adjourned.

WEDNESDAY, MAY 7, 1884.

THE PATENT MEDICINE ACT AND SALES OF DRUGS.

THE anomalous nature of many of the statutes designed for the protection of the public health, has often engaged the attention of those whose interest has been excited in this direction; but recent events have revealed certain consequences entailed by the working of the Patent Medicine Stamp Act, which for strangeness and inconsistency cannot be equalled. Some time ago we drew attention briefly to this matter, when describing a correspondence between Messrs. Christy and Co., wholesale druggists in the City, and the Inland Revenue Commissioners, relative to the manufacture and sale of menthol. It will be remembered that Messrs. Christy had prepared this drug in the form of cones, consisting of wax to the amount of ten per cent. of the whole, saturated with menthol, and which have been found of high value in the treatment of facial neuralgia. Naturally, in such a case the firm in question did not *protect* the preparation by resorting to the expedient of a Government duty stamp; nor, it may be added, do they in any case affect this mode of sale, no form of so-called patent medicine being ever issued from their establishment.

Accordingly, they were served with a notice from the

Inland Revenue Department requiring them to either withdraw the preparation, or to sell it only with the addition of a patent medicine stamp on every package, the penalty for non-compliance being £10 for every separate parcel sold. Monstrous as it may seem, this proceeding is perfectly legitimate on the part of the Government, to whom the power of insisting on such degradation of *bona fide* remedies to the low level of a patent medicine, is given by the existing Act in all those cases where drugs are sold in any form other than that of absolute purity, without admixture of any description whatever.

On being made acquainted with these facts, which at first sight appeared, very naturally, to be incredible, we resolved to make full inquiry into them and the incidence of a law that permits the probability of such wholesale consequences to druggists and chemists of every description. The result, however, is, that we are unwillingly compelled to admit that a most improper and dangerous power of injuriously affecting both the public welfare and the private interests of chemists, is to be found in the enactment under cover of which Messrs. Christy have been persecuted in the manner alluded to above. It will doubtless be a revelation to many, if not to all, the chemists now transacting an ordinary retail business, to be informed that no single day passes without their being guilty of transactions for which they expose themselves to fines amounting in the aggregate to, possibly, thousands of pounds. Many of this class of dealers, for instance, are accustomed, especially in the poorer quarters of cities and large towns, to sell scores, or it may be hundreds of boxes of ointment, bottles of cough mixture, pennyworths of pills, and packets of powders. *For every individual sale of this description, when the article is unprotected by a patent stamp, a penalty of £10 is incurred.* In order to prove the accuracy of this statement, it is only necessary to quote from the Stamp Act the following passage, which declares that medicines charged with stamp duty include "Foreign medicines of all kinds except drugs, and also all other pills, powders, lozenges, tinctures, potions, cordials, electuaries, plasters, unguents, salves, ointments, drops, lotions, oils, spirits, medicated herbs and waters, chemical and officinal preparations whatsoever, to be used or applied externally or internally as medicines or medicaments, for the prevention, cure, or relief of any disorder or complaint incident to or in any wise affecting the human body, made, prepared, uttered, vended, or exposed to sale by any person or persons whatsoever." It might be urged, however, that this paragraph has reference only to secret remedies the composition of which is not explained on the notice respecting them affixed to the package. Such a conceit is nevertheless shown to be altogether vain, both by the action of the Commissioners towards Messrs. Christy, who published a full description of their menthol cones with each box, as, indeed, is their practice in all cases, and also by a subsequent paragraph in the document we have already quoted from, and which, in dealing with "exemptions," expressly states—"All medicinal drugs whatsoever which shall be uttered or vended entire, without any mixture or composition with any other drug or ingredient whatsoever."

It is impossible in the face of this explicit declaration to avoid the conclusion, even had it not been already practically enforced, that no description of *compound*, though it be but peppermint water, designed to afford relief to a symptom, can be legally sold without the protection of a Government stamp. It is amusing to note the other exemptions mentioned in addition to the pure, unmixed drugs. They are thus given:—"Ginger and peppermint lozenges or any other article of confectionery, unless the person vending the same shall vend the same as medicines or as beneficial for the prevention, cure, or relief of any distemper, malady, ailment, or disorder incident to or in anywise affecting the human body. All artificial mineral waters, and all waters impregnated with soda or mineral alkali, or with carbonic acid gas, and all compositions in a liquid or solid state to be used for the purpose of compounding or making any of the said waters."

There is one other provision in this most curious statute, designed apparently for the utter extinction of the last remaining hope of a harassed chemist, and which effectually removes the possibility of defence on the ground of a general knowledge of the non-occult nature of a compound. It runs thus:—"Or which have at any time heretofore been, now are, or shall hereafter be, by any public notice or advertisement, or by any written or printed papers or hand-bills, or by any label or words written or printed, affixed to or delivered with any packet, box, bottle, phial, or other inclosure containing the same, held out or recommended to the public by the makers, vendors, or proprietors thereof as nostrums, or proprietary medicines, or as specifics, or as beneficial to the prevention, cure, or relief of any distemper, malady, ailment, disorder, or complaint, incident to or in anywise affecting the human body."

We have quoted thus largely from the statute in question in order that no misconception concerning its extent and meaning may be entertained, and with a view to exciting a definite attention to it for the purpose of promoting measures for amendment in all important particulars. As will have been rendered clear, it is no imaginary danger that threatens chemists so long as the Act remains in force. Any one of the class may, to-morrow, be summoned for selling to an informer a single pennyworth of spermaceti ointment, or of cough lozenges; inasmuch as the object of the preparation in either case, is "the prevention, cure, or relief of a disorder or complaint incident to or in anywise affecting the human body." It might, perhaps, be advisable, as a means of stirring general interest in the question, for an informer to make a few purchases of this description, and subsequently lay an information against the chemists from whom the mixed drugs had been obtained. Unpleasant as such a course would of necessity be, it would equally of necessity lead to combined action for the protection of the whole class, by procuring the repeal of what is at present a most unjust and deplorable law, and one calculated to perpetuate the worst evils of quackery. That it has so long been permitted to continue unamended is certainly due to the fact that its provisions have been known to only a few who, like Messrs. Christy, have been subjected to its consequences

or who, in an official capacity, have made themselves acquainted with all that concerns the pharmaceutical calling.

Even medical practitioners, also, may be brought within the influence of the ridiculous penal clauses quoted above; for whoever is accustomed to dispense his own prescriptions must thereby contravene the express directions laid down, unless he retains a supply of patent medicine stamps ready for affixing to each bottle or box that leaves his surgery. It will certainly be a novelty in professional life if, as seems possible, every country practitioner is required to arm himself with a sheaf of these Government protectives against prosecution; but it will be an embarrassing matter sometimes, to appraise the value of a bottle of medicine, as must be done ere the proper stamp can be affixed.

Indeed, the ludicrous side of the subject is as prominent as the grave aspect of it; and however regarded, it is emphatically clear that some immediate steps to remove so gross a potentiality for abuse and degradation ought to be taken; and the most efficient way that can be proposed is the formation of a common league, whose objects shall be to obtain the urgently needed amendments of the Act.

THE SCOTCH CORPORATIONS AND MEDICAL REFORM.

IN a few weeks the revised regulations relating to the conjoined examinations and the course of study required of candidates will be laid before the profession. As far as we have been able to judge, these appear to need little, if any, alteration, and have evidently been framed with a just regard to the present demands of medical education. How they will be carried out is another matter, and time will of course be required before any opinion can be formed with regard to them. It is for us now to show where they may fail. It is proposed that a conjoint board shall be formed of delegates from the three Corporations whose duty it shall be to regulate and fix the periods of examination, to arrange for the visitation of examinations, fix the fees, &c. The Board does not select the examiners; these are to be appointed by the individual Corporations. These appointments, if made as we have recently shown, apparently annually, but virtually for life, will not remove the very state of things which we have tried to expose, and have repeatedly condemned. But the question may arise if the Board elected under the provisions of the Bill now before Parliament would improve matters in this respect. The probability is that a worse conditions of things should be brought about, and that the court of examiners would be packed with relations and friends of members of the Board. It is to be hoped that recent criticisms on the hole-and-corner methods of electing examiners practised by the Corporations will prevent a recurrence of the abuse. It may fairly be stated that the present proposals of the Corporations are as sound as any suggested by the Medical Bill, and it may also be remarked that the weak point in both is the absence of a constant visitation of the examinations. Without this no

guarantee can be given that the standard of examination will be maintained under either Board, that of the Corporations or that of the Bill. The perfection of the Conjoint Corporation Scheme would be ensured by inspectors appointed and paid by an enlarged and representative Medical Council being present at every examination. The system of sporadic visitation is absurd, the only result being a periodic slaughter of candidates as a proof of the stringency of the examination. The cry for legislation is to a great extent based on the statement that the Scotch Corporations are too lax in their examinational tests, and it has also been suggested that the cry has been intensified by the jealousy felt by the English Corporations, due to the fact that such a large number of students come to Edinburgh to qualify. Be this as it may, the Scotch Corporations are justified in retorting that they consider their examinations quite good enough to supply their home wants, and that if candidates come from other countries they are not to blame. Looked at with every wish to be fair and just, the conjoint scheme with the regulations proposed by the Corporations for medical education appears as good as that suggested in the Medical Bill, while they both are weak, as before referred to, in the provision for the visitation of examinations. We have not touched the question whether the Universities should be included in the conjoint scheme. To apply the same rules to the Universities of Scotland and of England would not be fair. The English Universities turn out so few graduates annually that the competency or incompetency of these is of comparatively little moment; but with regard to the Scotch Universities the question is different. It may be fairly argued that they have to some extent levelled downwards, and that the teaching in them does not quite come up to the ideal University type, but it can never be said or even suggested that they do not turn out men as good as any one-portal system can hope to do.

HOPE AS A REMEDY AGAINST DISEASE.

IN commenting upon Dr. J. Mortimer Granville's letter to the *Times* (*Med. Press*, p. 387), we had no desire to charge that gentleman with plagiarism, but simply to note how closely two minds could think and express themselves alike upon the same subject, and at the same time, independently of one another—a strong proof, we take it, of the great importance of the subject dealt with. We regret that Dr. Granville is not of one mind with us as to the necessity of great caution in the choice of topics suitable for writing upon in the columns of the lay press, when the writer's own name and address are appended thereto. We should not have had much fault to find had his letter appeared under some such signature as "A Consulting Physician," but we still think that the connection of his name and address with such a subject, and such a manner of treating it, cannot, upon calm reflection, commend itself to Dr. Granville's own approval. We cannot bring ourselves to believe that he would approve of medical men throughout the country writing to their local press, advocating or deprecating certain forms o

treatment, denouncing the conduct of others, and by contrast commending their own; yet this is what would surely take place if his example is to be followed and approved. The evil Dr. Granville complains of in his letter to this journal last week is certainly a grave one, and one deserving of our best efforts to do away with, but we are convinced, that sowing distrust in the minds of the public generally as to the reliability of medical skill, and the soundness of medical opinion, is not the best method of accomplishing the object he has in view. Like a two-edged sword, the remedy would cut in opposite directions: some might be gainers by setting their medical adviser's opinions at defiance, but beyond a doubt, others would be the sufferers from carelessness of the warnings they had received, and neglect of those proper measures and precautions which experience teaches are essential to their safety and restoration to health. Surely Dr. Granville does not wish to lay it down as a broad rule, to be observed by the public, that when, after careful examination, they have been pronounced the subjects of "tubercle, cancer, heart or kidney disease," they are at once to set their medical adviser at defiance, neglect all forms of treatment, and follow out any line of life they please, going in for high living, hard drinking, late sittings, exposure to every vicissitude of weather, and violent exercise, as affording them the best chances of a prolonged life. We grant that there are *some* cases that do bear, and will bear, such a course of treatment with benefit, but they are by no means in the majority; those that bear it are cases in which the disease is not of a very pronounced type, and in which hope and enjoyment in life are almost sufficient to trample upon the efforts of disease.

We need scarcely say that we are gratified by Dr. Granville's approval of what we have written, and he may safely accept our assurance that we have no desire in any way to hurt his feelings. In reference to his letters, we hold the opinion strongly that it would have been far better to have withheld his name and address, and thus avoid the appearance of bringing his own opinions into favourable contrast with what he declares to be the procedure of but too many of his professional brethren. We do not for a moment say that he meant in any way to advertise himself at the expense of his brethren, but there is no getting over the fact that the course he has adopted is open to such an interpretation. In our opinion, the best and wisest course to take is, to impress upon our brethren the error they make in shutting out "Hope" from the minds of their patients, and thus depriving themselves of a powerful ally in the treatment of disease. This seems a wiser course to pursue than to sow the seeds of distrust in the minds of the public, who are but too prone to fly to extremes under the influence of such teachings, and who are not best qualified to judge of what Dr. Granville's real meaning may be. We are satisfied that in nine-tenths of the minds of those amongst the laity who have read his letter the first thoughts have been, "A very sensible letter, a very sensible man; that is the man I shall consult if anything is wrong with me."

We have no hesitation in saying the views expressed are most sensible, and are sure that they are a just reflection of their author's mind; further, we are sure that Dr.

Granville is a safe and most trustworthy consultant, in whom, those amongst his professional brethren, and amongst the public generally, who benefit by his experience and opinion, have every good reason to trust; the only points of difference between us are, that we cannot look with approval upon the publication of such a letter in the columns of the lay press with his name and address attached; nor are we altogether convinced that he is quite loyal to his professional brethren in directing his efforts to educating the public in the direction of a contemptuous indifference or disregard of their medical adviser's opinion, where an adverse prognosis has been given, rather than to educating the members of the profession to a more hopeful spirit in their dealings with their patients, and to a horror of fixing a limit to the recuperative powers of Nature or the beneficial results of treatment. We are hopeful, that, upon reconsidering our views, Dr. Granville will be inclined to agree with us, and at least credit us with honest criticism.

Notes on Current Topics.

Cholera on board H.M.S. "Croccodile."

A COMPLETE history of the recent outbreak of cholera on H.M.S. *Croccodile* has yet to be given. No doubt the occurrence will in due course become the subject of official inquiry, and it is hoped that the results of that inquiry may be made public. For the present the chief points to be noticed in connection with that outbreak are the following:—The passengers, consisting for the most part of invalids and time-expired men, embarked on board the *Croccodile* at Bombay on the 2nd April, and on the day following the vessel sailed. In this interval a warrant officer died on board, the assigned cause of his death, *diarrhœa*. Subsequent deaths from cholera occurred as follows, namely, one on the 8th, one on the 18th, three on the 20th, and one on the 24th. The dates of attack are not given. "Several" cases of *choleraic diarrhœa* meantime occurred. Three soldiers, four children, and one lady, the wife of an officer, died during the passage to England, their deaths not in any case being due to cholera; and on the arrival of the transport at Portsmouth on the 29th of April the official report given in stated that the latest attack of cholera took place on the 20th of that month.

From these particulars several questions of importance in relation to the outbreak present themselves. For example: In what respect other than in degree did the fatal case of *diarrhœa* and the others, said to have been of *choleraic diarrhœa*, differ from those of *cholera*? Did the first-named victim suffer from his disease at the time he embarked? and if so, had he come from an infected locality, or had he been in contact with an infected person? How far had medical treatment an influence in preventing cases of *choleraic diarrhœa* from developing into pure *cholera*? If it had such an influence, what were the therapeutic measures employed? Were there any other cases of *cholera* except the six in which death occurred? In the absence of particulars on this point the death-rate seems excessive. We willingly accord every credit to

the zeal with which "the most vigorous precautionary measures to arrest and stamp out the disease" were taken by the responsible medical officer on board. As a simple matter of history the circumstance is noteworthy that the usual period an outbreak of cholera lasts on board ship at sea is ten days, although in some instances it is considerably longer than this; yet notwithstanding all the measures above alluded to, the actual persistence of the disease in the *Crocodile* was seventeen days at the very least.

Pure Milk.

THE advantages of a pure milk supply can only be obtained under conditions which, until very recently, have not existed except in country districts; and even there, in those establishments only where the importance of sanitary precautions have been understood. Now, however, most large towns possess one or more centres of milk distribution, the arrangements of which have been devised, and the service of which is carried out, with every regard for the purity of the milk supplied, and the cleanliness of every article with which it comes into contact. Of the establishments of this description in London the youngest is the South Metropolitan Dairy, at Brixton, an opportunity of inspecting which was offered to all interested in the question of a pure milk supply, on Saturday last. The proprietors of the dairy, Messrs. Nash and Stephenson, have expended a considerable sum in transforming the premises they occupy into a model dairy, where they carry out the process of separating cream from milk by Laval's rotary separator, and where complete arrangements have been made for storing large supplies of milk, butter, and cream, and for distributing these articles. An admirable system of drainage has been carried out, whereby any possible contamination of the milk from this too frequent source of evil is made absolutely impossible; and an ingenious method of cleansing all milk cans, pails, and utensils by means of a steam blast, ensures the cleanliness of every receptacle employed in the business. The milk is obtained from distant country farms, under regular inspection; and judging from the samples exhibited to visitors on Saturday it is most excellent in quality. It is much to be desired that establishments like this South Metropolitan Dairy shall rapidly multiply in our midst; the improvement they tend to produce in the bills of mortality, amongst infants especially, is not the least of the benefits they confer.

Cremation.

AFTER several years of desultory consideration the cremation question has at length assumed the dignity and dimensions of a Parliamentary Bill, and under the protection of Dr. Cameron was, on Wednesday last, introduced into the House of Commons, on second reading of a measure for legalising the process. The numbers voting, for the Bill 79 to 149 against it, will probably surprise even those who were most sanguine of the result. They certainly indicate a fast growing opinion favourable to a scientific method of disposing of the dead; and probably the fearful truth enforced by rapid extension of dwellings on every side of suburban cemeteries, has done more than any amount of persuasion to convert public

opinion to an appreciation of the things that must be. It is, however, a little disheartening to observe a disposition to favour the notions of antiquity on the part of great officers of the State; nor when, as appeared from Sir William Harcourt's remarks, they incline to meet a demand for hygienic reform by irrelevant suggestions of absurd possibilities, is it a cheering indication of interest excited in the question at issue. Notwithstanding the opposition to the Bill, however, the friends of cremation may fairly claim to have gained a great success in obtaining the votes of seventy-nine legislators on behalf of the proposed reform. It is, also, an open secret that this number by no means exhausts the members of Parliament who are favourable to cremation, a good many having, through absence and other causes, been prevented from dividing on the Bill. With the encouragement afforded by this latest success, the agitation in favour of cremation cannot fail to make a great advance between this and the next occasion on which the House of Commons will be asked to assent to the regulation of this mode of disposing of the dead. Fortunately it does not require to be legalised, the law having already declared it to be no offence to cremate a dead body "with due regard for public decency." The English people, however, are eminently a law-abiding people, and will not kindly regard any system, whether for burying the dead, or for promoting the comfort of the living, to which a Parliamentary sanction has not been given. To obtain this for their plan is now the first aim of cremationists; and there is very good reason to hope that it will not be very long ere the efforts made in this direction will be completely successful.

The Diseased Meat Trade by the Dublin Guardians.

IN noticing in our last issue the abominable traffic in diseased meat for the use of the Dublin poor carried on by the Guardians of the Dublin Unions, we did the Local Government Board an injustice, which we are anxious publicly to correct. Being aware that the proceedings of the Guardians generally are under the special supervision and control of the Board, we complained that they permitted this disgusting traffic to continue, and we placed on them the responsibility of allowing it to proceed without official remonstrance. We find, however, that the administration of the Contagious Diseases (Animals) Act is not under the control of the Local Government Board, but is exercised by the Guardians, subject only to the authority of the Privy Council in Ireland. Something has indeed been done by the Local Government Board to discourage this traffic, for in October, 1882, Dr. MacCabe, inspector for the Local Government Board, held, at the request of the Privy Council, a long inquiry into the matter, and submitted a report, in which he expressed the opinion that it was undesirable to confer on veterinary inspectors the power to put pleuro-pneumonic meat on the market for consumption by the poor.

The facts connected with this trade in diseased meat by the Guardians are simply inconceivable. From the 20th July, 1882, to the 5th April, 1884, 879 animals had been slaughtered for pleuro-pneumonia in the South Dublin Union alone. Of these 155 were sent to the knacker, and

the remaining 724 were sent to the butcher, for which an average of £5 14s. per head was received. The profit on the sale of this carrion was therefore divided between the skink-butcher and the Guardians in the proportion of about 70 per cent. to the former and 30 per cent. to the Guardians. Out of the latter item must, of course, be deducted the expense to the Guardians of medical attendance and burial of the victims to whom the trading co-partnership sold this poisonous food, and who died of irritant poison in consequence. It is still more incredible that the expenditure under the Contagious Diseases (Animals) Act in Dublin alone is six times as great as the combined outlay of London, Birmingham, Liverpool, Manchester, Edinburgh, Glasgow, and Belfast. The following are the astounding figures :—

Expenditure on Cattle Disease Prevention.

Liverpool	...	...	£190	per annum.
Birmingham	...	...	800	"
Manchester	...	...	20	"
Edinburgh	...	...	464	"
Glasgow	...	...	582	"
Belfast	...	...	180	"
London	...	...	0	"
Total	...	...	£2,236	
			Dublin, £12,734!!!	

The Asclepiad.

NUMBER II. of Dr. B. W. Richardson's periodical work contains several papers of exceptional interest from their practical nature, as well as an eloquent and appreciative essay on "An Æsculapian Poet, John Keats," to which is appended a beautifully engraved steel portrait of Keats. Dr. Richardson expresses an unbounded admiration, not alone of Keats' poetical genius, but also of the capacity he evinced for the practice of the medical profession; "if Keats," he asserts, "had once tasted the true spirit of medicine, he would have become one of her greatest sons, an addition, perchance, to the eight or ten of the men of all time whom medicine claims as her own, her poets of Nature, like Keats himself, and in their way poetising in undying thoughts if not in measured lines." For the busy practitioner a collection of *opuscula practica* will be found to possess much practical usefulness, especially two notes, one on temporary preservation of post-mortem specimens, and the other on crushed ice and lard in the treatment of burns. A clinical study of aneurism of the coeliac axis is a carefully-written contribution to the literature of this branch of medicine; and a paper read before the Society of Arts recently on the reconstruction of London will engage at once the sympathies and thoughts of a good many smoke-wearied dwellers in the great metropolis. We cordially welcome this continuation of Dr. Richardson's original venture.

AN American contemporary says that a bill to regulate the practice of medicine and the sale of medicines in Utah was recently passed by the Legislature, but vetoed by the Governor, at the solicitation of certain patent medicine proprietors.

Buddhist Medical Jurisprudence.

THE meddlesome busybodies who seek to obtain the repeal of that useful and valuable enactment for the prevention of a transmissible disease may take a leaf out of the book of the "Allwise Buddha." The Buddhist law is significantly stringent on the point, so much so that, according to Jardine's translations of the Burman's law of "Marriage and Divorce" we observe that, should a man or woman unwittingly marry into a family afflicted with certain hereditary diseases, as leprosy, cancer, syphilis, madness, &c., which in the Dhammathat relating to marriage are collectively designated "*hinaroga*, or wasting diseases," he or she may sue out a divorce. Buddhists are taught to believe that, not only will the children of diseased parents inherit a transmissible disease, but that the husband or wife will contract the same by association—living together under the same roof. Doubtless the Buddhist law is an effective one for stamping out hereditary disease.

The Election of Examiners at the Royal College of Surgeons, Ireland.

THE annual election of the three courts of examiners, surgical, midwifery, and preliminary, took place on Tuesday afternoon, too late for us to announce the result in this issue. For the court of examiners for the Licence and Fellowship, nine new candidates presented themselves, while the outgoing members also offered themselves for re-election. The new candidates were Dr. Kilgariff, of the Mater Misericordiae Hospital; Dr. Franks, of the Adelaide; Dr. Ormsby, of the Meath; Dr. Boyd, of the Mater Misericordiae; Dr. Hayes, of Stevens's; Dr. Gogarty, Dr. C. H. Robinson, and Dr. P. C. Little. For the ophthalmic examinership Dr. Swanzy submitted his claims.

Transplantation of Healthy Skin in Lupus.

THE *Monatsh. für Prakt. Derm.* reports that Hahn has scraped out lupus-tissue and transplanted healthy skin to the fresh wound in five cases with good results. The patients were anaesthetised, and, after the scraping was finished and the bleeding arrested, which sometimes recurred after a few hours, the whole wound was covered by portions of skin about half a centimetre long and a quarter centimetre broad, the portions consisting only of cutis and epidermis. Under iodoform bandage, complete union of the transplanted portions occurred mostly in from five to eight days. A year had elapsed since the treatment of the first case, the cure being so far permanent, and no relapse having occurred.

WE are informed that the honorary title of M.D. of the St. Louis College of Physicians and Surgeons has been conferred on Mr. Gay, F.R.C.S., of London, "in recognition of his distinguished services to surgery."

WE regret to announce the sudden and unexpected death, last week, of Dr. Andrew Whyte Barclay, consulting physician to St. George's Hospital, and treasurer to the Royal College of Physicians of London, at the age of sixty-six.

Exclusion of Medical Men from the Magistracy.

THE refusal to admit Dr. Flannery to the Commission of the Peace, which was taken up so energetically in Parliament by Mr. Sexton, M.P., opens up a subject for just complaint against the action of the Irish Chancellor in dealing with the appointment of magistrates, and we learn with satisfaction that Dr. Lyons, M.P., has given notice that on the very earliest possible day he will call attention to the exclusion of members of the profession from the Commission of the Peace, and move a resolution.

The answers given by the Chief Secretary to Mr. Sexton's interrogatories are somewhat incomprehensible, and the only conclusion derivable from them is, that the appointment of magistrates is entirely a matter of the Lord Chancellor's whim, and not regulated by any well-considered determination. Mr. Trevelyan says that a rule to exclude dispensary medical officers was made in 1872, but he does not say by whom it was made, or by what authority, and he admits that, if such rule ever existed, it had been broken in several instances since then. With great respect for the Lord Chancellor's office, we deny his right to dispense the Commission of the Peace on any such principle. He is entrusted with the selection of suitable persons to serve Her Majesty, and we conceive his duty is to consider the claims of each individual, and not to exclude persons fully qualified and worthy because they belong to a class. It does not appear from what has transpired in the House that any reason has been assigned for this exclusion, which is the more insulting to the profession because it does not appear to be applied to any other class.

We have before us a list of medical practitioners holding the Commission of the Peace in Ireland, extracted from the official list of the Magistracy. Sixty-seven members of the profession hold the J.P., of whom twenty-three hold dispensaries, or held them when they were appointed magistrates. Nine are, or were, workhouse surgeons, and others held other official medical positions. Does anyone say that these gentlemen have manifested any unfitness for the office, either individually or as a class? If not, what justification can be shown for excluding professional men of similar position in the future?

A New Method of Removing Nasal Polypi.

In the *Canada Medical Record* Dr. Bell brings forward a new mode of treatment. It obviates any trouble from hæmorrhage, which is frequently the case when the forceps or hook is used; it is painless and very simple. He gets the patient to blow strongly through the affected nostril, closing the other with his finger. The polypus will be brought down so that it can be easily seen through the external nares; then with my hypodermic syringe charged with a solution of tannic acid in water (of the strength of twenty grains to the fluid drachm), I pierce the polypus with the needle, and inject ten, fifteen, or twenty minims of solution, according to the size of tumour. In a few days the polypus shrivels and dries up (tanned); it comes away without any trouble or pain,

and looks like a clot of dry blood, my patients usually removing it by blowing the nose or by their fingers.

THE mortality in Paris also from zymotic diseases is also very high, amounting last week to 128 fatal cases of diphtheria, measles, and typhoid.

DIPHTHERIA may almost be considered epidemic just now in Berlin, where the death rate from that cause is double that of all the large towns in the United Kingdom combined.

WE mentioned in our last that a C.B. was about to be conferred upon Dr. Arnold Royle, Physician in Ordinary to the late Duke of Albany. This distinction was officially gazetted on Friday last.

THE Council of the Linnean Society of New South Wales have offered a prize of £100 for an essay on "The Life-History of the Bacillus of Typhoid Fever," to be delivered by the 31st of December next.

LAST week the Duke of Westminster laid the foundation stone of a new wing of the London Temperance Hospital, Hampstead Road. The cost of the new wing will be £14,000, of which £7,000 has been subscribed or promised.

THE young Nizam of Hyderabad was recently attended by Dr. Beaumont, who watched his Highness through a serious attack of cholera. On his recovery the Nizam caused the sum of 31,000 rupees and jewellery of the value of 10,000 rupees to be sent to Dr. Beaumont for his fourteen days' professional attendance.

A CURIOUS misprint has crept into Messrs. Churchill's Medical Directory. At page 290 Mr. Savory is there described as President of the Royal College of Surgeons of England. We are sure the error has only to be pointed out to meet with ready correction. For the uninitiated we would add that Mr. John Marshall is President of the College.

M. J. DENIKER ("Comptes Rendus") describes a fœtus of the gorilla in the fifth month of its life. In almost every respect it approaches closely to the form of the human fœtus at the same age. The hand differs from that of the adult gorilla by the greater proportionate length of the fingers. The leg is cylindrical, without the projection of the calf evident in the human fœtus. The cephalic index is 86.2.

IN the principal foreign cities the rates of mortality per 1,000 of the various populations were, according to the latest official returns, as follow:—Calcutta 33, Bombay 27, Madras 68, Paris 27, Geneva 22, Brussels 24, Amsterdam 28, Rotterdam 29, The Hague 28, Copenhagen 26, Stockholm 25, Christiania 16, St. Petersburg 42, Berlin 24, Hamburg 27, Dresden 26, Breslau 34, Munich 34, Vienna 33, Prague 43, Trieste 28, Turin 38, Venice 19, Lisbon 31, New York 25, Brooklyn 18, Philadelphia 22, and Baltimore 18.

THE deaths registered last week in the principal large towns of the United Kingdom corresponded to an annual rate of 22·3 per 1,000 of their aggregate population. The death-rates in the several towns were:—Norwich 15; Derby, Bristol 16; Halifax 17; Hull, Leicester, Brighton, Birkenhead 18; Newcastle-on-Tyne 19; Huddersfield, Cardiff, Salford 20; London, Nottingham, Bradford 21; Portsmouth, Sunderland, Plymouth, Bolton, Edinburgh 22; Sheffield 23; Preston, Birmingham 24; Wolverhampton, Oldham 25; Manchester, Blackburn 27; Liverpool, Leeds, Dublin 28; Glasgow 29.

THE highest annual death-rates last week in the large towns from diseases of the zymotic class were—From whooping-cough, 2·3 in Liverpool, 1·8 in Huddersfield, and 1·5 in London; from measles, 6·7 in Wolverhampton, 4·3 in Portsmouth, and 2·7 in Leeds; and from scarlet fever, 2·1 in Sheffield, 1·7 in Cardiff, and 1·6 in Leeds and in Preston. The 31 deaths from diphtheria included 17 in London, 3 in Leeds, and 2 each in Glasgow, Edinburgh, and Portsmouth. Small-pox caused 12 deaths in London, 3 in Sheffield, 2 in Liverpool, 1 in Birmingham, 1 in Manchester, 1 in Sunderland, and 1 in Newcastle-upon-Tyne.

Scotland.

[FROM OUR NORTHERN CORRESPONDENTS.]

OBAN AS A HEALTH RESORT.—A curious report has reached us through a London source that this northern favourite watering-place is the seat of an outbreak of typhoid fever. In the interests not only of the town, but of the thousands who resort thither during the summer in quest of health and recreation, we are glad to be in a position to give to this rumour the most unqualified contradiction. No doubt the fame of the municipality of Oban has reached London, but it would be doing them an injustice to allege that they are wholly oblivious to the fact that Oban is nothing if not a fashionable watering-place, and that they have succeeded in nothing but rendering the natural charms of its situation unattractive, for there are natural beauties and advantages of climate which Vandalism cannot touch, nor supine indifference impair. On the score of its drainage, visitors and intending visitors to Oban may feel at ease, for a few years ago a most thorough system of drainage was carried out; it is now perfectly efficient, and finally a most abundant supply of wholesome water has been procured from a convenient neighbourhood. There are "fevers" and "fevers" in Oban, thanks to local sources; but of this we are assured, that for many years in Oban there has not been epidemic, either typhus, typhoid, or any other infectious fever, and we hope that no intended holiday in the West Highlands will be intercepted by any such idle rumours.

LEGACIES TO MEDICAL CHARITIES.—The late Mr. George Murray, C.A., has left, subject to a life rent by his sister, Miss Murray, the following legacies to charitable institutions in Edinburgh:—Royal Infirmary, £1,000; Sick Children's Hospital, £1,000.

EDINBURGH ROYAL HOSPITAL FOR SICK CHILDREN.—The directors of this hospital, at their meeting on the 29th ult., elected Professor Grainger Stewart to be one of the consulting physicians of the hospital in room of the late Dr. Charles Wilson. They also elected John Tawse Nisbet, M.B., C.M.,

to be resident physician, and Dr. W. J. Smith to be assistant to the extra physicians.

EDINBURGH ROYAL INFIRMARY.—The managers of the Edinburgh Royal Infirmary have elected Dr. W. Allan Jamieson as extra physician for diseases of the skin.

THE EDINBURGH MEDICAL SCHOOL.—SUMMER SESSION.—Nearly all the classes in the University of Edinburgh and the Extra-Mural School were opened on the 1st inst. The classes in the University Faculty of Medicine, except those of Botany, Natural History, Clinical Medicine and Clinical Surgery, meet now in the University new buildings.

THE EDINBURGH CITY HOSPITAL FOR EPIDEMIC DISEASES.

—The work which the Corporation last year took in hand of providing a new hospital for epidemic diseases is slowly approaching completion, but a great deal remains to be done before the building will be ready for the reception of patients. Happily, it is not at present required. The surgical hospital of the Old Infirmary has been transformed into what is intended to be an epidemic hospital, with separate departments for the more distinct forms of infectious diseases—small-pox, typhus, typhoid, and measles; and the interior is being arranged and fitted up under the supervision of the Medical Officer of Health, the Health Committee, and the City Superintendent of Works. The building is a very large one, and is being admirably adapted to all possible requirements of the city. As workmen are still employed on the building, and as the grounds have yet to be laid off, several weeks will elapse before the hospital can be said to be completed. Experiments are now being made in heating with a view to economy in the consumption of fuel and equality of temperature in the building heated by it.

GLASGOW DEATH-RATE.—For the week ending with Saturday, the 26th ult., the death-rate of Glasgow was 29 per 1,000 per annum, as against 25 in the preceding week and 35 in the corresponding week of last year.

HEALTH OF EDINBURGH.—For the week ending with Saturday, the 26th ult., the mortality in Edinburgh was 95, and the death-rate 20 per 1,000 per annum. Diseases of the chest accounted for 54 deaths, and zymotic causes for 12, of which 2 were due to fever, 1 to diphtheria, 1 to scarlatina, and 1 to measles.

Correspondence.

THE FUTURE OF THE ROYAL COLLEGE OF SURGEONS OF ENGLAND.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR.—There is one point in your recent articles in which I think you somewhat misconceive the action of the former councils of the College of Surgeons of England, as to the re-election of Presidents. Until the Charter of 1843, the Council was compelled to elect the "President" (or previous to the Charter of 1822 "The Master,") from out of the Court of Examiners. In the Charter of 1800 is the following:—"And then and there elect, choose, and appoint one of the Examiners, by the majority of votes of such of the Court of Assistants as shall be present, one person to be principal Master." In the Charter of 1843 is the following:—"That the President and Vice-Presidents of the said College shall no longer be chosen exclusively out of the Court of Examiners of the said College, but from or out of all the members of the Council indifferently, and whether Examiners of the College or not." Until 1863, the Council resolutely acted in opposition to this almost direction of the Crown to do otherwise, and continued appointing the Presidents from the Court of Examiners only, the result being that persons became examiners and continued to hold the post until their time for election to President came.

I am, yours, &c.,
LEX.

May 2, 1884

HOPE AS A REMEDY AGAINST DISEASE.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—Dr. Mortimer Granville's communication on the above subject to the *Medical Press* of April 30 suggests a problem in medical ethics which even his accomplished powers have failed to solve to the satisfaction of the profession, however satisfied he may himself be at the result of his pleadings. As "a consulting physician in a very exclusive sense" (*O! vir fortunatissimus!*), your correspondent claims to an independence of thought and expression which less happily placed practitioners can only admire in the abstract; but the lay journals would, notwithstanding the defence uttered by Dr. Granville, be sorry reading to the general profession, as well as to "non-exclusive" consultants, did every "consultant in a very exclusive sense" hurry to the *Times* or other organ of public opinion with a record of each bright idea that troubled his brain. We are told, however, that in this instance, "the despair I deprecate is something on the mind of the patient, not on that of the doctor." After this it will need no very great refinement of casuistry to justify an appeal to the public, in the public press, by any and every doctor anxious to undertake the cure of an ache, or a swelling, or a cough, or a fracture; whenever, in fact, an affliction is present to the body of the patient, and not to the practitioner who so eloquently asks for confidence in himself. But surely, Sir, the time has now arrived when dignity and good seeming alike demand that rules tacitly admitted as guides for conduct by an overwhelming majority of medical men shall not be ignored by the few who choose to think themselves superior to their fellows on the score of "exclusiveness." "Thou shalt not advertise" is a commandment in itself; and whoever accepts any pretext, however specious, for posing before the public in a *professional garb*, very necessarily thereby exposes himself to a charge that no amount of verbiage can repel, and the nature of which no amount of explanation can palliate. As an independent reader of Dr. Granville's original letter to the *Times*, I was affected by it in a way that its author would scarcely appreciate; and it is certain that a similar feeling of regret and despair was aroused by it in the mind of every medical man who saw it, and sorrowed over the picture it revealed. Dr. Granville's theories are amusing as a rule; occasionally they are even valuable; and when announced in a fit and proper place, the columns of a medical journal, they are not likely to do much more than excite good-humoured consideration; addressed to those who are likely to be patients rather than critics, they are eminently out of place, even when the author is actuated by "an inner sense of right."

Yours faithfully,

SPKS ABSIT.

May 2nd, 1884.

MEDICAL REFORM.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—Now that this so-called measure of medical reform is before the House of Commons, may I ask your kind permission to make a few remarks on the subject? This much talked of Bill, in my opinion, and that of the vast bulk of the general practitioners of the country, is simply giving us a stone when we have asked and asked long and persistently for bread.

The Right Hon. A. Mundella may be, and no doubt is, thoroughly competent to frame laws having regard to the Nottingham stocking trade. But, may I be permitted to say, that the manufacture of stockings, even the fact that his fortune has been made out of that very respectable and useful trade, does not tend to render that estimable gentleman an infallible authority on medical reform.

It appears to me that so far as the thousands of medical practitioners are concerned the wonderful Bill is simply useless. What better will we be when it is law, are our interests more securely guarded, what possible good can it do us? We do not want, and have not asked that the old and honourable corporations should be plundered and left high and dry. We do not ask that the entrance to the profession should be made an impossibility to men of ordinary capacity and diligence. This Bill is the outcome of a clique of crotchet mongers, and has not the good will of the men who have the power, would they only use it, to compel would-be members of Parliament to respect their interests.

Now, Sir, it may be all very well to legislate for the future of the profession, but we belong to the present, and "sufficient for the day are the evils thereof." What we want, and what we have and will ask for, is *uniformity all round*. Why should medical men all over the world possess uniformity, and we be denied it? Why should we have a hundred and one titles, when there is only one recognised elsewhere? We ask that the title to practise should be uniform, as in other countries, and that it should represent complete qualification, that there should be no piecemeal qualifications. That, in fact, one title should be granted to all fully qualified medical practitioners, and that title should represent the legal medical and surgical qualification of the country, and that as in France, Germany, and America, there should be no other title or distinction recognised by law. That, Sir, is what we want, and what, if we act together, we will get.

I am, &c.,

WILLIAM DONOVAN.

Willow, Romsey, April 23rd, 1884.

[It is hardly necessary to say that we do not agree with our correspondent, for we do not in the least anticipate that by the Bill any of the Corporations will be "plundered and left high and dry," or that "the entrance to the profession will be made an impossibility to men of ordinary capacity and diligence." To suppose that the Medical Bill would have any such effect is a complete hallucination, begotten of ignorance of the contents of the Bill; and if its passing involved any such result we should be the last to support it. The uniformity of the educational standard, which Dr. Donovan considers so indispensable, is provided for by the Bill, and the enemies of reform use this fact against the Bill. We think the Bill excellent in principle, but altogether faulty in detail, and our efforts shall be directed to amend its shortcomings when it reaches the committee stage.—Ed.]

DR. MILLER ON DENTAL CARIES.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—May I ask you to allow me, through your columns, to correct a slight mistake that I have observed in the *Medical Press*, April 30th, 1884. In reference to Dr. Miller, of Berlin, and his paper on caries, it is stated that he first promulgated the theory that the first stage was due to the action of acid produced by micro-organic fermentation, and the second due to a more direct action of micro-organisms. This view of caries was laid before the profession by Mr. Milles and myself at the International Medical Congress in the August of 1881, and I am not aware of any previous statement of it; certainly, in the discussion on that paper no allusion was made to any previous suggestion of a similar view by Dr. Miller or anyone else, although the speakers were representative men from America, Germany, and England, and would hardly have been ignorant of such previous statement had it existed. Mr. Tomes drew particular attention to the theory being then broached for the first time.

Faithfully yours,

ARTHUR S. UNDERWOOD.

11 Bedford Square, W.C.
1st May, 1884.

Literature.

DISEASES OF THE BLADDER, PROSTATE GLAND, AND URETHRA. (a)

MR. GANT's well known and excellent work comes now before us in a fifth edition, a fact which testifies amply to the estimate formed of it by the medical profession, and places it almost beyond the sphere of the reviewer. The special features of this edition are as follows:—The surgical anatomy of the bladder, prostate gland, and urethra, has been revised from

(a) "Diseases of the Bladder, Prostate Gland, and Urethra." By Frederick James Gant, F.R.C.S. &c. Fifth Edition. London: Baillière, Tindall, & Cox. 1884.

careful dissections made by the author at the Royal College of Surgeons; and this serves as the basis for the discussion of the various methods of examination, and the necessary operative procedure pertaining to the organs in question. Additional matter to the extent of 144 pages has been added, and an extent of ground is thus covered which overtakes possibly more than that of any other work in this branch of surgery. In some works there is an excessive reference to authorities, but if Mr. Gant's work errs at all in this connection, it is in such reference being too infrequent; indeed, it is only in the chapter on the chemistry of the urine and urinary deposits that they exist at all. There is a note to Mr. Gant's preface in which he remarks that he "has written this treatise in a purely technical form, for the guidance of the profession only; and thus to render the whole as unintelligible as possible to the public. The majority of the latter class would, indeed, be better able to walk barefooted to Jerusalem, than to rightly comprehend the greater portion of the text." We have no sympathy whatever for the writing of a book for the public under a professional guise—a dodge by no means infrequent in the metropolis—but we are afraid that the line of demarcation between the intelligence of a high class and well educated layman, and of a member of the profession is not so well defined that an endeavour to exclude the former by studied technicality might result in similarly influencing the latter. We are glad to note, however, that Mr. Gant's style is clear and intelligible, without the slightest taint of pandering to the public taste, but in our opinion the enigmatical addendum to his preface is uncalled for.

In the chapter on "Functional Disorders of the Bladder" Mr. Gant describes Paget's "Stammering of the Bladder" under the questionable term "Impotency of the Bladder." This condition, when existing apart from paralysis of the bladder, is essentially a nervous affection rarely calling for surgical or other interference, and we agree with Mr. Gant that in its treatment no medicinal agents have any certain efficacy. The discussion of sexual diseases is entirely passed over. The chapter on "Diseases and Injuries of the Bladder," is, by no means, so full as we should have expected it to be, considering the attention given to this subject in recent times, and numerous contributions thereon in medical journals during the past year.

The chapter on "Urinary Calculus, Lithotomy and Lithotripsy" is the best and most complete in the book. In the chapter on "Diseases of the Prostate Gland," *Prostatorrhoea* is properly noted as one of the symptoms of chronic inflammation of the prostate. The diagnosis of *prostatorrhoea* from gonorrhoea is easy, but we do not agree with Mr. Gant that it is equally easy as between this condition and *spermatorrhoea*, as we are perfectly satisfied that in certain cases of *chronic prostatitis spermatozoa* are found in the viscid discharge eliminated both at stool and after micturition. In the treatment of chronic inflammation of the prostate, the author recommends blistering to the perineum, and the occasional application of nitrate of silver in the form of an armed bougie. We think the occasional passing (perhaps once or twice a week) of a large catheter should have been enjoined, and we are certain that even without medication whatever, this is a means of treatment productive of the happiest results. Mr. Gant does not smear his catheters with any germicide, and for this omission we are not disposed to find any fault with him, believing as we do that the theory on which this is based is almost played out.

In view of the important social question involved we agree with Mr. Gant in giving prominence to the difficulty of distinguishing between specific (so-called) and non-specific, urethritis, for we have abandoned the opinion once held that gonorrhoea is invariably of venereal origin, satisfied as we now are that virtuous women occasionally cause urethral discharges in their husbands which it is impossible to distinguish from typical gonorrhoea. To maintain, as has been quite recently done in our esteemed contemporary, the *Edinburgh Medical Journal*, that only *gonorrhoea begets gonorrhoea* implies that no natural combination of circumstances could have originated it, and forces us to the absurd conclusion of a *special creation*! Touching the important subject in a medico legal aspect, we have recently seen in the out-door department of one of the largest hospitals in the Kingdom (and many such cases have come under our notice), a sturmount little girl of seven suffering from a copious purulent vaginal discharge. Let a case of this description be coupled with a false accusation against a man possibly suffering from urethritis and accompanying discharge received from his wife, and what wrongful and un-

warrantable conclusions might be deduced! In the treatment of gleet Mr. Gant recommends bichloride of mercury, as originally suggested by Dr. Campbell Black; but at the strength of the lotion $\frac{1}{4}$ gr. to an ounce of water.

Sir Andrew Clark's sensation over "Catheter Life" and "Catheter Fever" does not seem to have made much impression on Mr. Gant. The chapter on Urinary Deposits is valuable, though it is to be regretted that the various formulae are given in the old notation.

Altogether, the book is one which we can honestly recommend as resulting from a wide field of personal experience, coupled with an extensive knowledge of the practice of contemporary surgeons. The illustrations are good, the writing is agreeable, and the various subjects are well arranged and comprehensively treated. A word of praise is due to the publishers for the manner in which their part of the work has been executed.

Medico-Parliamentary.

THE LUNACY LAWS.

IN the House of Lords on Monday last, the Earl of MILLTOWN called attention to the observations made by Mr. Baron Huddleston in the case of "Weldon v. Winslow" as to the state of the Lunacy Laws, read the report of the case and the remarks of the learned Judge, who expressed his astonishment that a person could be confined in an asylum by anybody on the statement of anybody, provided certain formalities were gone through, and who had also observed that it was positively shocking that such a state of things should exist, and moved that the present laws constituted a grave public danger and should be amended.

The Earl of SHAFTESBURY, as Chairman of the Lunacy Commission for upwards of fifty years, declined to enter into the case of Mrs. Weldon whilst it was *sub judice*. He could only observe that the matter never came officially before the Commissioners; and he did not hesitate to say that if the case were as bad as it had been represented, it would not invalidate all the proofs that could be given of the good working of the Acts which now regulated the treatment of lunacy. It should be remembered that the granting of lunacy certificates was safeguarded by severe restrictions and penalties. No medical man could officiate in matters of this kind unless, as laid down under the Act of 1873, he was a physician, surgeon, or apothecary. The Medical Act of 1853 prescribed the strictest regulations, and any person negligently or improperly granting a certificate was liable to the severest punishment.

Lord COLERIDGE said his experience of private lunatics had not been happy. He did not mean to say that there were not good men among the keepers of private lunatic asylums, but he was afraid that the men who were most concerned in the keeping of these private asylums were not intellectual, and were not, perhaps, in all respects, the highest type of medical men. There were exceptions, no doubt. He attributed this fact to the circumstance that the subject was not attractive to the highest type of mind, and secondly, and much more, to the circumstance that the highest type of men did not like to mix themselves up with any system which was a system of trade. He could not help thinking that it ought not to be the interest of anybody to retard the cure of a patient. It was the interest of a public lunatic asylum to get rid of its patients, because the patients cost money, instead of paying it. He did not mean to say that this was a matter which was to be decided hastily, but as a matter of principle he must say that his experience had convinced him that it was not safe to give a medical man a pecuniary interest in the maintenance of his patient. In other cases of illness a medical man would be anxious for a speedy cure, because it would raise his reputation; but in the case of lunacy there was no such inducement, because in the event of a cure the subject was not one that any one would naturally like to speak about in society. In fact it was the very last subject that the relatives of the patient would care to talk about.

The Lord CHANCELLOR hoped the motion would not be acceded to because although the Acts were open to amendment, they did not deserve the sweeping condemnation which those who knew little of their working had indulged in. With regard to private asylums the greatest difference of opinion existed; but it was within his knowledge that

not a few of them were conducted by medical men of the highest character and the greatest professional attainments. He (the Lord Chancellor) would undertake, on behalf of the Government, that next session, if they still remained in office, a Bill would be presented to Parliament, the object of which would be the consolidation of the existing law, with such improvements as were recommended by the Committee of 1878, and such others as, after due consideration, might commend themselves to the Government. Meantime, he hoped the motion would not be pressed.

After a few words from Lords Salisbury and Stanley, the motion was by leave withdrawn.

A DEPUTATION waited on the Home Secretary yesterday (Tuesday) for the purpose of urging the immediate repeal of the Contagious Diseases Acts.

ON Monday last, Mrs. Gladstone formally opened another "lung" for London, the site being old Horsemonger Lane Gaol. The building having fallen into disuse, the ground was purchased for the use of the public, and has been planted and laid out for recreation, in the midst of a densely populated and poor district.

AT a meeting of the Council of the London Hospitals Sunday Fund, on Monday, presided over by the Lord Mayor, it was decided by a large majority that the Hospital for Incurables, as at present administered, could not participate in the benefits of the fund.

WHEN the vote of supply for the Army Medical Department came on in the House of Commons, on Monday last, Mr. Dawney opposed the present system of organisation, and advocated a return to the old regimental system. The proposal was, however, met with such a decided negative by subsequent speakers, that the vote was passed almost unanimously.

THE annual *conversazione* of the Medical Society of London was held on Monday evening, when an oration was delivered by Dr. Theodore Williams. The rooms of the Society were filled to their utmost capacity, and the orator, who has just returned from the Mediterranean after a serious illness, was very warmly received.

University of London.—The following gentlemen were, at the meeting of the Senate held on Thursday last, elected examiners for 1884-5:—Chemistry: Prof. J. Emerson Reynolds, M.D., F.R.S.; and Prof. T. E. Thorpe, Ph.D., F.R.S. Botany and Vegetable Physiology: Prof. Bayley Balfour, M.D., C.M., D.Sc.; and Sydney H. Vines, D.Sc., M.A. Comparative Anatomy and Zoology: Prof. E. Ray Lankester, M.A., F.R.S.; and Prof. Alexander Macalister, M.D., M.A., F.R.S. Practice of Medicine: W. H. Broadbent, M.D.; and W. Miller Ord, M.D. Surgery: Sir William MacCormac, M.Ch., M.A.; and Prof. John Wood, F.R.S. Anatomy: Prof. D. J. Cunningham, M.D., C.M., F.R.S.E.; and H. Greenway Howse, M.S., M.B. Physiology: Prof. Arthur Gamgee, M.D., F.R.S.; and Prof. Gerald F. Yeo, M.D. Obstetric Medicine: J. M. Duncan, M.D., LL.D., F.R.S.; and John Williams, M.D. Materia Medica and Pharmaceutical Chemistry: T. Lauder Brunton, M.D., C.M., D.Sc., F.R.S.; and Prof. F. T. Roberts, M.D., B.Sc. Forensic Medicine: Augustus J. Pepper, M.S., M.B.; and Prof. George Vivian Poore, M.D., B.S.

Royal College of Surgeons of England.—The following are additional lists of candidates who have passed the examinations for Membership to those published in our last:

The following were admitted Members of the College on Monday, April 28th:—

Agar, S. Hollingsworth, L.S.A.
Biggs, C. Mount, L.R.C.P.Lond.
Gannan, David Peter, M.D. Dub.
Kendle, Frederic Wellesley
Morini, W. R. de, L.R.C.P.Lond.

Murray, R. W., L.R.C.P.Lond.
Perry, Allan, L.S.A.
Pleasse, Charles Henry, L.S.A.
Strugnell, Walter Thomas, L.S.A.
Turner, Frederic Senior

The following were admitted Members of the College on Tuesday, April 29th:—

Bailey, William Henry, L.S.A.
Brickwell, Henry Taylor, L.S.A.
Cooper, H. C. Evans
Freeland, Ernest Harding, L.S.A.
Jackson, Paul, L.S.A.
Jollye, Arthur Dixon, L.S.A.

Lankester, Herbert Henry, L.S.A.
Mander, Percy Robert, L.S.A.
Newnam, E. Edmund, L.S.A.
Parker, Herbert
Roberts, S. M. Pearson

The following were admitted Members of the College on Wednesday, April 30th:—

Alsop, Clement, L.S.A.
Deare, Arthur C., L.R.C.P.Lond.
Frames, Alfred Cromwell, L.S.A.
Graham, Hugh Henry, M.B.
Hayward, Arthur Ernest, L.S.A.

Hitchens, Frank, L.S.A.
Martland, Percy E., L.R.C.P.Lond.
Menzies, James Herbert, L.S.A.
Roe, Montagu Walter, L.S.A.
Wetwan, William Albert, L.S.A.

The following gentlemen were admitted Members of the College on the 1st inst.:—

Dean, Francis, L.S.A.
Edwards, C. Reginald
Stace, A. Frank, L.S.A.

Sumpter, W. J. Ernely, L.S.A.
Tuckett, W. Reginald, L.S.A.

Two hundred and thirty-three candidates were admitted to the final examination for the Membership of the College at the recent meetings of the Court, of whom 105 received their diplomas, 53 passed in surgery to qualify in medicine and midwifery, and 75 were referred.

University of Durham.—The following, having passed the necessary examination at the Easter Term, have received their degrees:—

M.B. in Medicine and Surgery.

First Class Honours.—None.

Second Class Honours (in Order of Merit).—Arthur Hardwick, Philip Percy Manning, Edward Samuel Gooddy.

M.B. without Honours (arranged alphabetically).

Anderson, Maurice Abbott
Bass, Frederick
Biggam, William
Bradbury, Arnold Francis
Brodrick, Harry Edward
Daigleish, John William
Dove, Augustus Charles
Gregory, Alfred John
Hare, Everard, M.R.C.S.
Hickey, Evan Lewis
Jones, John Lloyd Thomas
Lansdale, William

Lyth, Edgar Roe
Montague, Arthur John Helm
O'Connor, Charles Patrick
Phillips, Edward
Pocock, Alfred G. G.
Benney, Henry
Richardson, James N., M.R.C.S.
Steele, William Frederick
Sugden, Edward Scott
Sumpter, Berners George
Walker, Charles Pope
Whyte, A.

Re-Examination in Chemistry only.

Harling, Thomas
Plummer, Henry B. Wetherall

Bumboll, Charles Frederic
Sugden, Edgar B.

Re-Examination in Botany only.

Cranston, George
Cross, Henry W.

Rayner, Hugh, M.R.C.S.

The following passed in Anatomy, Physiology, and Chemistry:

Essery, William Joseph

Mitchell, Richard Pryce.

The following passed in Anatomy, Physiology, and Botany:—

Baumgartner, Harry Spelman

Dixon, Charles Frederick Lyne

Certificates of Proficiency in Sanitary Science.—Joseph Auspicio Simoons M.D. Brus.; L.M.S. Bombay; L.R.C.P. Lond. Francis John Walker M.R.C.S., L.R.C.P., L.S.A.

Notices to Correspondents.

CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a *distinctive signature or initials*, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

LOCAL REPORTS AND NEWS.—Correspondents desirous of drawing attention to these are requested kindly to mark the newspapers when sending them to the Editor.

READING CASES.—Cloth board cases, gilt-lettered, containing 26 strings for holding each volume of the *Medical Press* and *Irregular*, may now be had at either office of this Journal, price 2s. 6d. These cases will be found very useful to keep each weekly number intact, clean, and flat after it has passed through the post.

EFFECTS OF WATER-GAS ON HEALTH.

A MEETING of the State Board of Health was recently held in New York, to consider the resolution of the Legislature asking whether water-gas was injurious to health. The question was referred to the public analysts, and upon their report, says the *Sanitary Engineer*, the Board based a reply to the resolution, to the effect that water-gas, as ordinarily used, was not more dangerous to health than other illuminating gases.

INQUIRENS.—A Fellowship does not carry the right to use of "Dr." by the holder, though this prefix is usually conceded to Fellows of the London, Dublin, and Edinburgh Colleges of Physicians.

M.R.C.P.—1. Yes. 2. He was appointed Treasurer of the College some few months back on the resignation of Dr. Farre.

A MEMBER OF THE COLLEGE.—It is an error in Messrs. Churchill's Directory; the names would appear to have been transposed. Mr. John Marshall is President, and Mr. Savory is at present one of the Vice-Presidents of the College.

THE TREATMENT OF ITCH.

J. W. D. asks: 1. What is the formula for ung. sulph. co.? 2. When the Medical Bill becomes law, what action will be taken with those members of the profession who hold only one qualification? 3. A patient of mine who has had gonorrhoea for a period of eighteen months, but who is now better, has lately had nocturnal emissions, with very perceptible streaks of blood through them. What is the cause, and what treatment would you recommend?

[1. Unguentum sulphuris comp., commonly known as "Trooper's Ointment," from being used for the treatment of recruits suffering from itch. There is no official formula; but the following will be found to answer: B Sulphur flour, oz. ias.; lard, oz. iv.; soft soap, dr. ij.; extract of marshmallows, dr. ij. Misce. Fiat unguentum. The patient is stripped naked, and well rubbed with this ointment on the affected parts. The rest of his body is well lathered. After sitting (of course in a warm room) for half-an-hour, he enters a hot bath, whence he emerges with a skin as soft as an infant. The theory of this process is that the soft soap removes the external scales of the cuticle, opens up the burrows of the acarus, and gives the sulphur fair play. One application often succeeds in curing the itch. Of course, the marshmallows are to soothe the skin from the irritating effects of the soft soap. 2. The Medical Bill will not prejudice the rights of existing practitioners in any way. Whether they hold one or many diplomas they will occupy the same position as the State examinee under the Bill. 3. Your patient is suffering from urethral irritation, accompanied by slight ulceration. Give him the following: R Decortum pareire, ad oz. viij; potassae bicarb., oz. ss.; tinct. nucis vomice, dr. ij. M. Fiat mistura. Two tablespoonfuls three times a day. If the urethral running continue, employ the Broun injection. No alcoholic stimulants.—Ed.]

DR. J. W. MARTIN (Sheffield).—We hope to commence your paper in our next. The delay has been unavoidable.

DR. ARCHER (Liverpool) will find the desired reference in another column.

MR. E. M. BEAL (Hammermith).—An article "On Poisoning by Ammoniated and Red Oxide of Mercury" was contributed by Messrs. Hendley and Benham, and will be found in our columns for April 16.

VINDEX (Glasgow) has forgotten to enclose his card. We have, however, already adverted upon the unprofessional method of advertising adopted by Mr. Sutherland, who, we fear, is beyond the pale which influences gentlemen in their regard for the honour and dignity of professional life.

TEMPERANCE DRINKS.

To the Editor of the MEDICAL PRESS AND CIRCULAR.

SIR,—For the description of the six varieties of unintoxicating wine printed on the menu card at the luncheon of the Society for the Study and Cure of Inebriety, I am responsible. These wines are all the genuine juice of the grape from their several native vineyards, and are a much purer wine than any of the intoxicating wines commonly in use in this country. I am happy to be able to state that these unintoxicating wines were highly commended by many of the guests, and that already they have found their way on fashionable dinner tables. They were described by me in your columns a few years ago, have been exhibited at medical meetings, and have been adopted by several influential medical men in London and the provinces, both as a social beverage and a pleasant, valuable, therapeutic remedy.

There is little relish in England for genuine fermented wine, our taste has become so corrupted by the spirituous fortification called for by the English market. A few days ago a well-known Englishman, on tasting a glass of pure, unsophisticated sherry, brought over from Spain by his host, a wine-grower, exclaimed, to the latter's amusement, "This is mere vinegar and water!"

42 Grove Road, Regent's Park.

Yours, &c.,
NORMAN KERR, M.D.

WHAT IS MEDICAL ADVERTISING?—Our correspondent's letter upon this absorbing question is unavoidably held over this week.

A FELLOW OF THE COLLEGE.—The announcement had not been received at the time of going to press; we are unable, therefore, to give you the information asked for.

SANITAS.—The Health Exhibition will be opened to-morrow by H.R.H. the Duke of Cambridge. The Prince of Wales had originally promised to perform the ceremony, but is prevented on account of the death of his brother.

Meetings of the Societies.

WEDNESDAY, MAY 7TH.

OBSTETRICAL SOCIETY OF LONDON.—At 8 p.m., Specimens will be shown by Dr. Cleveland, Dr. Matthews Duncan, Dr. John Williams,

Mr. Alban Doran, and others.—Dr. Arthur Mitchell, Strong Mental Emotion affecting Pregnant Women as a Cause of Iodicy in the Offspring.—Dr. Mathieson, Case of Extra-uterine Gestation; delivery of living child per vaginam; removal of placenta; recovery.

THURSDAY, MAY 8TH.

OPHTHALMOLOGICAL SOCIETY OF THE UNITED KINGDOM.—At 8 p.m., Living Specimens. At 8.30 p.m., Dr. Stephen Mackenzie, A Case of Extreme Tortuosity of the Retinal Vessels.—Mr. Nettleship: (1) Peculiar Changes in the Choroid after Papillitis. (2) A Case of Central Choroiditis.—Mr. Adams Frost: (1) Ossification of Choroid causing repeated attacks of Sympathetic Irritation. (2) Recent Injury, with Detachment of Retina and Choroid. (3) Detachment of Retina and Organised Blood-clot after an old Injury.—Dr. C. K. Fitzgerald: (1) An Instrument for showing the Action of Accommodation. (2) Acute Spasm of the Accommodation.—Messrs. Gunn and Anderson, A Case of Nerve Disease with Ocular symptoms, including alleged monocular diplopia.—Mr. Higgins, Remarks on Extraction of Cataract.—Mr. H. S. Morton, Case of Haemorrhage at Region of Macula.—Mr. Nettleship: (1) Cases of recovery from Amaurosis in Infants. (2) Cases of Retrocular Neuritis.—Mr. Adams Frost: (1) Chiliary Staphylococci following Irido-Choroiditis. (2) Sympathetic Ophthalmitis subsequent to Excision.

FRIDAY, MAY 9TH.

CLINICAL SOCIETY OF LONDON.—At 8.30 p.m., Mr. Clutton, A Case of Intestinal Obstruction caused by a Diverticulum successfully treated.—Mr. Christopher Heath, Cases illustrating the Treatment of Fracture of the Patella.—Dr. Whipple, Case of Hydrocephalus of old standing; insanity; death.—Mr. William Anderson, Case of Pyloric Lithotomy.—Mr. Charters J. Symonds; A Case of Ruptured Brachial Plexus.

SATURDAY, MAY 10TH.

ROYAL INSTITUTION.—At 8 p.m., Mr. Westropp, On Roman Archaeology.

Vacancies.

Coombe Hospital, Dublin.—Assistant Master. Applications to Master, or at Coombe Hospital.
Dunabaghlin Union, Dunbayne Dispensary.—Medical Officer. Salary, £123. Election, May 17.
Royal South London Dispensary.—Resident Medical Officer and Dispenser. Salary, £100, with furnished apartments, &c. Applications to the Committee by May 12.
Salop Infirmary, Shrewsbury.—House Surgeon. Salary, £100, with board. Applications to the Board of Directors before May 12.
The Hospital for Sick Children, Great Ormond Street, W.C.—Assistant Physician. Applications to the Secretary by May 14.
West Norfolk Hospital, Lynn.—House Surgeon and Secretary Salary, £100, with board. Applications to the Secretary before May 2.
Worcester General Infirmary.—House Surgeon. Salary, £100, with board and lodging. Applications to the Secretary, 50 Foregate Street, Worcester, by May 10.

Appointments.

JACKSON, H., M.R.C.S., Medical Officer of Health for the Borough of Barnstable.
JONES, G. H. W., M.R.C.S., Medical Officer for the Eokington District of the Chesterfield Union.
MACNAMARA, DR. G., Medical Officer of Health, Rural Sanitary District, Trim Union.
MAURICE, W. J., B.A. Oxon., M.R.C.S., L.R.C.P. Lond., Assistant Surgeon to the Royal Berks Hospital.
PATERSON, W. B., M.R.C.S., L.D.S., Medical Tutor to the Dental Hospital of London.
STOKES, A., M.B., C.M., L.R.C.S. Ed., Senior House Surgeon to the Liverpool Children's Infirmary.
STRICKLAND, C. E., L.K.Q.C.P.I., M.R.C.S., Medical Officer for the Kidsgrove District of the Woolston Union.
STURGES, O., M.D. Cantab., F.R.C.P. L., promoted to the Senior Staff of the Hospital for Sick Children, Great Ormond Street, London.
WATSON, J. W., M.R.C.S., Medical Officer for the Fourth District of the Ashby-de-la-Zouch Union.
WILSON, E., M.R.C.S., Medical Officer for the Grantham District of the Grantham Union.

Births.

CABLE.—April 30, at Royal Hill, Greenwich, the wife of G. H. Cable, M.R.C.S., of a son.

Deaths.

BARCLAY.—April 28, at Whitney Wood, Stevenage, Herts, after a few days' illness, Andrew Whyte Barclay, M.D., aged 68.
BELL.—April 25, at Florence, Italy, Marian Witherington Bell, wife of Vernon Bell, M.D.
BIBBY.—April 2, at 60 Green Street, Grosvenor Square, Samuel Hale Bibby, M.R.C.S.
MOORE.—April 27, at 7 Museum Street, Ipswich, Harry Gage Moore, M.D., aged 42.
RIGGS.—April 26, at his residence, Richmond Terrace, Armagh, James Ledlie Riggs, M.D., aged 60.
TAYLOR.—April 23, at his residence, Ebury Street, Eton Square, S.W., Theophilus Taylor M.R.C.S., aged 60.
WOOD.—April 27, at Beacon Hill, Lichfield, Brigade-Surgeon John Wood, 28th and 64th Regimental Districts, aged 53.
WOODCOCK.—April 26, W. Plant Woodcock (in practice prior to 1816), late of Holcombe, Lancashire, aged 88.

A CASE OF SPORADIC CRETINISM, WITH APPEARANCE OF MYXŒDEMA. (a)

By AMAND ROUTH, M.D., B.S., M.R.C.P.,

Assistant Obstetric Physician, Charing Cross Hospital; Physician, Samaritan Free Hospital for Women and Children.

ELIZ. H., æt. 25½, is an inmate of the Home for Female Incurables, Marylebone Road, and was born near Southampton, in Hampshire. She was the eldest of four children, both parents being quite healthy when she was born, being respectively 24 and 22 years of age. The father, however, died twelve years afterwards, and the mother sixteen years afterwards, both of consumption—a disease which also caused the death of the patient's own sister, æt. 17, and her mother's sister, æt. 27. The father was born in Hampshire, the mother in Berkshire, and there was no blood-relationship between them.

Up to the age of 7 years the patient was just like other children, but plumper than usual, and always looked like a "large white pudding," being "fat, flabby, and of a doughy-white colour." Whilst pregnant with this patient the mother was frightened by a bull. At 7 years of age the girl ceased growing taller, but continued growing stouter and flabbier, becoming slow in all her movements, and so stupid that all attempts at teaching her to read or write were fruitless. At 8 years of age the child came to London, and beyond getting less able to help herself and more silly-looking, the friends say there has been little or no change, with the exception that latterly she has become thinner.

Family History.—Beyond the apparent heredity of consumption, there is no family history of any disease, such as syphilis or Bright's disease, and no history of alcoholism, neither is there any history of insanity or cretinism in the family. A sister of the patient, æt. 23, is a fairly healthy-looking girl, well-developed, and

regular in all her functions, though somewhat anæmic. She has, however, an enlarged thyroid gland, now somewhat diminished under treatment, and there is a systolic murmur to be heard at the heart's apex and left axilla, dating from an attack of acute rheumatism three years ago. The patient also has a healthy brother, æt. 19, now in the army. All the children were born in Hampshire.

Present State.—Height, 3ft. 5in., the average height of a child of 5 years of age. Weight, 4st. 2lbs. 12ozs. She is much stunted in growth, and her bony skeleton is very considerably altered by rickety changes. Thus, there is a lateral curvature of the spine in the dorsal region, with the ribs thereby secondarily distorted. Lordosis is well marked. The tibiae are curved. The epiphyses of the bones of the lower limbs are somewhat enlarged, and the ribs beaded at their junction with their cartilages. The head is very dolicho-cephalic—a condition of the skull which Dr. Gee has stated is often due to rickets. Some of these bony changes are not unlike those described by Dr. Barlow and Mr. Bowlby as occurring in foetal rickets (sporadic cretinism as it occurs in the foetus?), and it is possible that one reason why they do not coincide more exactly is that in this case these changes may not have occurred till 7 years of age, when the sporadic cretinism first became apparent. The face is absolutely expressionless, and the lines obliterated. The features are swollen; the lips thickened, high-coloured, and shapeless; the mouth usually open; the nose is flattened and broadened between the eyes, and the nostrils dilated; the ears large and flat. The head does not hang forward, but the neck appears shortened, being lost in the supra-clavicular tumefaction.

The Skin is everywhere waxy-looking and pallid, with the exception of the face, where there is a slight flush, absent at times, over the flabby, pendulous cheeks, and on the feet and legs, where the circulation is so poor that a state of chronic chilblain exists. The skin is dry and rough in parts, but the palms of the hands are occasionally moist. The hands are spade-like in form. There is no true œdema.

(a) Read before the Medical Society of London, March 17th, 1884.

The Hair is jet black, and fairly plentiful, but very harsh.

The temperature of the body averages 98.8° F. in rectum, but the surface temperature is always sub-normal, being usually between 95° and 96° in the axilla or groin. Once only was it as high as 97°, and that was after the patient had been covered up in bed for some hours.

The Thyroid Body cannot be felt. Above the clavicle on either side, and to a less extent immediately below that bone, are well-marked *tumefactions*, which slip away when grasped, and though somewhat resembling lipomatous or myxomatous tissue to the fingers, also remind one of the sensation conveyed by grasping a varicocele. A clear respiratory murmur can be heard over the swellings, but no venous bruit. Similar subcutaneous swellings can be felt over the ribs in posterior axillary line.

The Abdomen is tumid and pendulous, owing partly to the shallow pelvis.

The Umbilicus is protruded, and the recti are non-adherent in the middle line.

The patient can walk slowly and tottering for short distances, but often falls suddenly, so never walks without assistance being at hand. The legs seem unable to bear the weight of the body, and give way suddenly at the ankle or knees. She has free movement of her arms, but does everything very slowly and methodically, yet quite unhesitatingly. She does not dress herself, because she would be all the morning doing so, but can put on or off her clothes if allowed to take her own time.

The Speech is slow and monotonous, and pitched in a high key. She answers questions correctly enough, but her answers are delayed. She appears to take a longer time than usual to understand a question, and then to require a still longer time to frame the reply.

Nervous System.—Patient can neither read nor write, and every attempt to teach her anything has failed; in fact, it is impossible to keep her attention concentrated. She cannot remember recent events, but can recall events which occurred before she left Hampshire at 7 years of age, the growth of both body and mind seeming to have been then arrested. She sleeps well and heavily. She is almost absolutely indifferent to pain, yet often complains of feeling cold. The "knee reflexes" are exaggerated; and Dr. Angel Money drew my attention to Gower's "front tap contraction," which is also well marked. Nothing appears to interest her for more than a few seconds, but when cheerily spoken to a momentary gleam of pleasure flits across her face. Otherwise, her expression is always motionless, callous, and somewhat sad.

The Eyesight is good, and ophthalmoscopic appearances normal. Pupils are somewhat dilated, and rather sluggish.

Urinary Organs.—Patient passes on an average 25 ozs. of urine in 24 hours. Sp. g., 1015. There is no sugar, albumen, or casts. The urea is deficient, being only about one-third of the normal quantity, viz., 10½ grammes, or 172 grains per diem (percentage 1.3). This result was obtained by the method devised by Drs. Russell and West.

Digestion, Organs of.—The tongue is not notably enlarged, nor indented by the teeth; the faucial arch is broad; the teeth are badly formed, and several have been removed, being decayed. The alveolar processes are unusually prominent, and the mucous membrane of the gums much thickened. Patient's appetite is good; her breath is usually foul; her bowels constipated. She constantly complains of a nasty bitter taste in her mouth.

Organs of Circulation.—Pulse 72. It is very difficult to feel the pulse at the wrist owing to its distance from the surface, and its weakness. The heart-sounds are normal but weak.

The Blood.—The blood was very kindly examined for

me by Dr. Montagu Murray by means of Dr. Gower's hæmocytometer and hæmodynamometer, as well as microscopically. Dr. Murray states that the proportion of white to red corpuscles is about 1 to 250; that the percentage of red blood discs to the normal standard is 86; whilst the percentage of hæmoglobin is 77. There was no obvious change in the appearance of the blood corpuscles, red or white.

Organs of Respiration.—Quite normal in every respect.

Liver and Spleen.—Nothing abnormal is to be made out in these organs. They are not perceptibly enlarged.

Generative Organs.—Patient has never menstruated. There is no leucorrhœa. The external organs are quite undeveloped, and destitute of hair. The labia minora are elongated and thickened, protruding some distance from the vulva. The mammae are quite infantile. The vagina and os uteri are normal. Per rectum, the pelvis is found to be infantile in shape and size, and the uterus is half its normal adult size, but normal in shape and position. The ovaries lie against the sides of the pelvis, lower and more posterior than usual, and are, at least, twice their normal bulk; and are softer than usual, and cause no sense of pain when grasped between the finger in the rectum and the hand on the abdomen. It is probable that the ovaries have undergone a change analogous to myxœdema, which would account for the persistent amenorrhœa, and the infantile condition of both external and internal organs of generation.

Remarks.—I first saw this patient on account of her chilblains, and because the other inmates of the "Home for Incurables," where she is staying, complained of her bad breath. I believed the case to be sporadic cretinism, with myxœdema, and this diagnosis was kindly confirmed subsequently by Drs. Gowers, Ord, Barlow, and my father. Dr. Ord pointed out that the bony deformities appeared to be of rickety nature. The case agrees in most of its features with the description given by Sir William Gull and the late Dr. Hilton Fagge, in their papers on sporadic cretinism—especially as possessing the subcutaneous symmetrical swellings, as first pointed out by Mr. Curling, and considered by many, and by Dr. Ord in particular, to be similar to myxœdema, a disease named and described by that gentleman in 1878. In his paper read before the Medico Chir. Soc. in 1871, the late Dr.

Hilton Fagge laid stress upon the fact that sporadic cretinism was probably due to atrophy of the thyroid, and he further stated that he believed that a healthy, and still more an enlarged, thyroid was to be regarded as a safeguard against cretinism—in other words, that a healthy thyroid exercised a protective influence over the production of cretinism. He showed that in countries where cretinism was endemic, those who had the largest goitres were not cretins at all; and that a large goitre protected the individual from the more severe effects of cretinism. He further showed that in England the cause of cretinism, whatever it may be, only acts with a low power, which is expended in producing goitrous enlargements of the thyroid, but that if this cause of cretinism should act upon a person with an undeveloped or absent thyroid no such protective influence could be afforded, and cretinism would result. This case lends some little support to this theory, which has not hitherto been much entertained.

The exact relationship between myxœdema and sporadic cretinism is not yet made out. Sir William Gull and Dr. Fagge showed that sporadic cretinism was invariably associated with the presence of symmetrical tumours in the supra-clavicular, and other regions; but their relative priority is unknown. In Dr. Hilton Fagge's four cases, those in which the cretinism had lasted the longest, had these symmetrical swellings the least well-marked, and *vice versa*. Hence it would seem that the myxœdema, if such it be, decreased as the cretinism increased. The case I am showing this evening also seems to indicate this, as the girl has latterly been getting thinner and losing weight. The cretinoid change does not appear to have commenced in this case till 7 years of age, up to which time the patient was much as other children, and this is in accordance with Dr. Fagge's remark that sporadic cretinism may arise as late as the 8th year. It would, however, seem, from the aunt's description of the case, that in this patient the myxœdema had commenced much earlier; for she says the patient, as a baby, always looked "fat and flabby," and like a "doughy white pudding," a very fair popular description, I think, of a myxœdematous baby. This description is also in accord with that given before the Sardinian Commission on Cretinism, by Foederé, who states that those infants destined to become cretins have a body extraordinarily voluminous, and are mostly œdematous. There is reason, therefore, for believing that myxœdema precedes, or, at all events, may precede the development of sporadic cretinism. It seems now also clearly made out that non-development or atrophy of the thyroid gland precedes both myxœdema and sporadic cretinism. In his paper on myxœdema read before the Med. Chir. Soc. in 1878, Dr. Ord suggested that the mucous œdema might precede the atrophy of the thyroid, but the cases of Mr. Curling, the papers of Sir William Gull and Dr. Fagge, together with Kocher's remarkable results following complete extirpation of the thyroid gland, as narrated by Dr. Felix Semon, have led Dr. Ord lately to admit that evidence is now tending to show that atrophy of the thyroid gland precedes the myxœdema.

Resumé.—No date can be fixed in this case for the atrophy of the thyroid gland, but it seems likely that it is a case of intra-uterine non-development of the gland, tending first to myxœdema, and secondarily to cretinism, for we have a clear history that the mother, whilst pregnant with this child, was frightened and chased by a bull, and maternal fright during pregnancy was given by Dr. Hilton Fagge as having occurred in one of his four cases. After birth, up to 7 years of age, the child's general appearance was that of a myxœdematous baby. At that age sporadic cretinism supervened; whilst quite latterly the mucous œdema has been showing signs of subsidence. The girl continues to be under medical supervision at the above-named establishment.

ULCERATIVE SORE-THROAT AND DEFECTIVE DRAINAGE.

By JOHN W. MARTIN, M.D.

THE following brief notes may prove interesting to those readers of the *Medical Press and Circular* who have seen similar cases in their practice.

On the 15th of May, 1883, I was asked to see a lady, living in one of the pleasantest suburbs of Sheffield, and in a house which had been built by its first owner for himself, every care being taken to make it a well-built, desirable residence. The lady was suffering from a very severe attack of ulcerative sore-throat, and great prostration of strength. The tonsils were pitted with ulcerations, and the surface of each tonsil was covered with pus. I learned that this form of sore-throat had been going through the house. The cook had been the first to suffer, then the housemaid, then the mistress of the house; finally, on the 18th, the master of the house was seized with a similar attack, in which the throat symptoms were slight, but the constitutional disturbance and subsequent prostration were most marked; the convalescence, in the case of all the parties, was slow and tedious. In spite of the assurances I received, the furred tongue, prominent papillæ, and triangular, reddish-looking tip, all made me feel convinced that I had sewer-gas poisoning to deal with. In spite of the gentleman's conviction to the contrary, I insisted upon the condition of the drains being examined into. This was done, with the following result:—The house is square-shaped, built on a steeply-sloping bank, the first floor and hall being on a level with the ground in front, the basement floor opening through the passage on to the garden level. On the right of the house, when facing it, is a large greenhouse and vinery. The morning room at the back of the house is directly over the coach-house, and communicates with the green-house; underneath the latter lies the coal-cellar, in the front part of which is the servants' water-closet.

The soil-pipe was imperfectly ventilated, but was found properly trapped before discharging into the main drain; this latter ran from the rear of the house to the right, at a sharp angle, and received, in the first place an untrapped sewer from the coach-house, through which the sewer-gas was discharged immediately beneath the breakfast-room, in which, the gentleman of the house and his wife spent most of their time when at home, in the second place, the sewer from the servants' w.c. The pipes in the main drain, and drain from the servants' w.c. were unusually large, and difficult to flush. Where the latter drain joined on to the main drain, it was found, that from the first the joint had been defective. When the junction was being made, evidently the workman had not a proper pipe for the purpose, so contented himself with simply chipping the edges of an ordinary pipe into shape, making it fit as best it might. A large piece had been broken off, and a gap left, through which there was free escape of the liquid contents of the sewer, and soakage of the surrounding ground; the drains at the point of junction were choked with night-soil, the passage being completely plugged. Two barrowfuls of night-soil were taken out of the sewer. The quality of the sewer-gas which was forced back through the servants' w.c. and through the coach-house sewer may be easily imagined. The pipe from the kitchen sink was also discovered to be broken, and choked with the greasy mass that is usually found, the result of kitchen refuse water.

No wonder that both the master and mistress of the house had not been feeling well for the previous year. The latter has felt tired, out of sorts, disinclined for exertion, and suffered from stomach derangement, and constant sore and relaxed throats, attended by a severe cough, which latter was thought due to chest trouble by her former medical attendant. The former has always had a nasty tongue, dyspepsia, and a special liability to colds; he also felt tired, and found business often a trouble to him, although of a very active turn of mind.

The drains being now put thoroughly in order, it is to be hoped that there may be a change in the condition of health of the inmates of the house. The gentleman told me the other day of the experience of a friend of his, whose suspicions had been aroused as to the condition of the drains of his house. He had bought the house from the man who had built it for his own occupation; by him he had been assured that the drains were in perfect order, and that he had specially supervised their construction himself.

On opening the drains it was discovered that the men, when making the drain, had come to a rock, and stopped there, thus failing to make any connection between the house drain and the town sewer. This "danger to health" is beautifully shown in Plate XLIII. of Teale's "Dangers to Health, a Pictorial Guide to Sanitary Defects," a book that ought to be in the hands of every medical man, every architect, every plumber, and every building contractor in the world, placing as it would do plainly before their notice the terrible dangers arising from defective drainage, and how to avoid them.

Examples such as the foregoing may, I think, be taken as evidence of the frightful reality of those dangers to health which are said to be the result of defective drainage. Every such example that comes under the notice of medical men ought to be noted and published, so that in time a sufficient bulk of evidence might be collected and tabulated, in order that the construction of defective drains might be made a criminal offence. Surely it ought to be so, since the evil, and often fatal results that accrue are the result of either culpable negligence or wilful and a downright criminal disregard of human life for the purpose of pecuniary gain. The one offence ought to rank as manslaughter; but where broken and defective pipes are put in from the outset, or where such a thing occurs as that which I have recorded, viz., no connection made between the house and town drain, the crime might well take its place as that of wilful murder, since it is quite as heinous as the work of the poisoner, for whom no one has compassion or mercy.

Dec. 13.—Since writing the foregoing I have had several fresh illustrations of the dangers arising from defective drainage in the persons of patients whose ill-health could clearly be traced to this source.

About a week ago also I had (I had almost said the pleasure) the opportunity of seeing a most flagrant example of defective drain-pipes being carted to new building grounds; these pipes could not be decently described, in the language of the building trade, as even "seconds." They were decidedly bad "thirds," or even "fourths." As far as I could see, there was not a decently sound pipe in the whole cartload. Flaws, cracks, portions chipped out of the joints abounded. As a sanitary philanthropist, one felt grieved to see how little way sanitation had made in the hearts of jerry-builders, or on the conscientious supervision on the part of those in authority over such promoters of increased mortality tables—as a medical man who has his bread and butter to earn—one felt a certain grim cynical satisfaction in thinking how little chance there is, despite our unselfish efforts to promote the health of the people, of our services being dispensed with. If ever these gentlemen, the jerry-builders, meet together for a festive dinner, surely amongst their toasts must be found "The Medical Profession: may it never be short of infectious disease." We can well imagine how impressively the gentleman entrusted with the toast would speak in favour of the vast benefits conferred upon humanity by cultivating and encouraging such conditions in the building of houses as are most favourable to the origin and spread of such diseases, as a field for clinical observation, study, and experience in treatment, on the part of our profession, and how earnestly he would dwell upon the dangers of abolishing such opportunities for study by attention to proper sanitary arrangements and precautions. One can also imagine the warm reception such a toast would receive. Increasing experience of the building that goes on in new districts makes

one incredulous of the benefits to be derived from the services of borough surveyors and borough medical health officers, who are bound so to serve their local masters, the sanitary authority of the place, as to secure for themselves a certain amount of comfort and security of tenure in their office. *Point de zèle* must be their motto. I have several patients at present on hand who are suffering from sewage poisoning, the sewage finding its way from the "middens" into the cellars of the houses they live in. The sanitary inspector has made several visits to these houses, but yet nothing has been done. Streets are allowed to be built, rotten foundations undrained, or most inefficiently so, put in without any veto being exercised by the sanitary authority. But these evils are all only too well known. To remedy them by active intervention seems to be nobody's business, and so the game of sickness and disease of a preventible type goes pleasantly on for the doctors, who seem to be the only people who vex their souls about the matter. I must close, but I would make what seem to me some fairly practical suggestions.

Could it not be made a criminal offence, punishable with a severe term of imprisonment, without the option of a fine, for any drain-pipe manufacturer to have in his possession so-called "seconds;" the offence to be aggravated if he attempts to sell such pipes. Equally should it be a criminal offence for any builder to have such pipes in his possession.

Could it not also be made an offence for any builder to proceed beyond the foundations of a house without a special certificate from both surveyor and health officer that all necessary conditions as to drainage, &c., had been complied with. This combined certificate would act as a check upon the proper supervision on the part of both these officers.

The inspection of drain-pipes should be made in the manufacturer's yard, all defective pipes being at once destroyed.

Finally, the profession ought not to rest until medical officers of health are placed upon the same footing as inspectors of mines and factories, i.e., independent of all local influence and interference, able to perform their duties without fear and without favour, and therefore efficiently.

Brunswick Street, Sheffield.

CONSUMPTION VIEWED IN RELATION TO EVOLUTION AND MOLECULAR ENERGY.

By WILLIAM H. PEARSE, M.D.,

Senior Physician to the Plymouth Public Dispensary.

THE commanding idea which must possess us in viewing Organic Nature, is that of its infinite complexity and involvement with, and of, all existences. The organic seems to be the so-far final, yet progressive, state of the series of all Forms, in their evolution and correlations; and in true and absolute "continuity." The "continuity" which the Organic shows in what we call "Disease" must be as absolute as in the periods or states we call Health, the two must be related absolutely in series. There can be no disruption, there can be but one system or order in Organic Nature. This great *a priori* "necessary truth," has been too much lost to European method and philosophy. The "specific" distinction between the organic and inorganic disappears. Life is the necessary state of the complex energies or modes of matter, motion, and their correlations, in absolute "continuity." Neither in the vast varieties of animal forms, past and present, or in the varying states and ages of individuals is the "form," (a) or evolving rate of life, absolutely fixed; in the

(a) The word "Form" seems greatly needed in modern philosophy. Bacon says, *Novum Organum* Book II., Ap. II., "For though in nature nothing really exists besides individual bodies, performing pure individual acts according to a fixed law, yet in philosophy this is not so."

prevailing series or rate, "varieties" occur. Such necessary and inherent variation may be toward new forms, which in suitable environment become, in the organic kingdom, "species," "genera," &c., having longer or shorter ages of approximatively fixed uniformity; or such variation may become natural organs or part of living beings; on the other hand, such variation may become disease in individuals.

In this view, disease comes to be viewed as part of an absolutely natural series. Again, as the great "form" of life is in absolute correlation to cosmic existence, so the deviations, variations, and diseases, can have no less wide correlations. It is thus just, in the study of any disease, to pay regard to all nearly associated phenomena, be they organic or inorganic. Hence our search for the true correlatives, which are essential to health, must be cosmic; inorganic, and in its dynamic modes; and organic. The past history of the growth of knowledge has often shown that the greatest generalisations have opened from the most common and simple facts, and no one can predicate in any unknown realm of nature, which direction of study shall give the "travelling instances," (a) which shall lead to the knowledge of the true "form" of any phenomena or disease. I beg, therefore, to record the careful but approximative observations, I have made up to this time, on the pre-phthysical and phthysical patients who have come before me. The facts will be of relative value, as pointing to the wide correlations (b) which phthisis has in the domains of the organic and inorganic, and to show how involved must be the true "form" of the disease. We must hold the *a priori* truth, that every function and action of health, and every function and action, of what we call disease, are traceable to modes of matter and "energy;" the order or rate of the series has not yet been recognised, but true method gives the "confidence of hope" that the rate or order may ere long be known.

The great mass of our therapeutics in the past and present, are early and crude efforts to correlate the deviations or diseases of the organic energy, into a harmony or mode, whose natural results shall be the rates we call health.

Whatever may be the intimate process in the final stage of phthisis, and when the lung tissue is invaded, we must remember that there are a long series of antecedent phenomena of functional development, involving nerve and molecular "energy" and that, even the tendency to phthisis, in any individual, has marked relationship to certain types of fundamental nerve and bone segments, of the living animal; and that these antecedent phenomena, both of structure and function, are correlated with heredity and atavism.

It must be of paramount importance in our hope of being able to compass the "form" of phthisis, and to prevent the evolution of the final stages, that we give due study to its less striking but important early processes. The prevention of the evolution of the later stages, the maintaining that state, perhaps not of the highest health, but of the comparative health, in which we see patients remaining for many years; the carrying the patients over the period of greatest tendency to phthisis, all this, more than the treatment of the established disease, must be the object of the physician. Whatever be the process in the lungs in the later stages, be it bacterial, cellular, &c., such must

be altogether minor parts of the great "form" of the disease, in comparison with nerve involvements, and the disturbed "energy" of nerve composition and structure, and yet more fundamentally of altered "molecular" action or direction. (a)

It must be perfectly within the lines of true scientific method for the physician to seek to modify the mode of vital energy of those who tend to phthisis, into that more perfect conservative "energy" of those who do not pass into phthisis. The vast influence of small amounts of mineral elements, and of slowly acting physical environment, in altering certain fundamental parts of body, e.g., the thickening of the basilar process in certain cretins, makes an *a priori* presumption that the healthy growth of the lungs must be within our control.

I have grouped my notes under a few heads as indicating, if not "an approximative generalisation, at least, the wide relation which phthisis has with the widest "forms" of biological evolution. My opportunity is the study of phthisis, is one of simple observation and record of the phenomena which cases present in the passing stream of dispensary patients. Not alone is the interest aroused by the cases of actual and advanced phthisis, but by the large number of cases, which as yet show the early and very varied phenomena, which, for varying periods, precede the actual phthisis. Since in dispensary practice so large a proportion are lost to observation after a few weeks' treatment, nothing like statistical accuracy is attainable; not the less it is true in medicine and biology, that some of the best knowledge and practice are from approximative observations, which as yet have fallen far short of laws or true "forms" of the complex phenomena involved. The very indefiniteness which dispensary practice must exhibit, has this profound and important lesson, in that it results from the immensity of the subject of phthisis, in its correlations or partship with so vast a variety of symptoms, order of occurrence, periods of duration, and types of physique, in the human beings in which they show.

Atavism (b).—The phenomena which the stream of living units present in their symptoms, both it may be of evolution and reversion, and exhibiting the "forms" of heredity and atavism, not only in symptoms but in organic type of form, will impress us with the truly cosmic relations which are involved in phthisis. But as the greatest general truths are to be seen, by a right method of mind, from the contemplation of single facts, I have thought the following approximative classification of some of the phenomena of phthisis, may help us towards grasping its true "form." The phenomena of phthisis as they come under our observation in advanced stages, are apt to absorb the mind and limit the breadth of our method in the study. The main conditions, and true parts, or earlier stages, of the series of phthisis, are in a great but varying degree, ever present. The great difficulty of the study is in the vast complexity of the organic evolution, and correlations of "energy" involved. But true method assures us, that as the all-sufficient vital "energy" exists

(a) Tyndall says "Heat as a Mode of Motion," 8rd edition, 1868, page 189: "The force of gravity almost vanishes in comparison with these molecular forces. . . ." Again, page 501, he says "Molecular forces determine the form which the solar energy will assume." And again, page 501, "All the philosophy of the present day tends . . . to show that it is the directing and compounding, in the organic world, of forces belonging equally to the inorganic, that constitutes the mystery and miracle of vitality.

(b) Darwin says: "It is probable that hardly a change of any kind affects either parent, without some mark being left on the germ. But on the doctrine of reversion . . . (Atavism) the germ becomes a far more marvellous object, for, besides the visible changes to which it is subjected, we must believe that it is crowded with invisible characters, proper to both sexes, to both the right and left side of the body, and to a long line of male and female ancestors, separated by hundreds and even thousands of generations, from the present time; and these characters, like those written on paper with invisible ink, all lie ready to be evolved under certain known or unknown conditions."—"The Variation of Animals and Plants under Domestication." Vol. II., 1868, page 61.

law, and the investigation, discovery, and explanation of it, is the foundation as well of knowledge as of operation. And it is this law, with its clauses, that I mean when I speak of 'Forms,' . . . And again, Aphor. XX, he says: "It is to be observed that the Form of a thing is to be found . . . in each and all the instances in which the thing itself is to be found; otherwise it would not be the Form . . . the Form is found much more conspicuous and evident in some instances than in others."

(a) "Travelling instances" are those which point out the motions of Nature in their gradual progress." Bacon, *Novum Organum*. Aphorism XLII., 2nd Book.

(b) Correlation is used in the sense of Darwin, *Correlation in the sense of Grove*.

up to a certain age of the individual, and as the failure of "energy" and healthy growth, takes place often very gradually, and in a relatively definite and orderly series, that thus the final and fatal phenomena are a true and natural series, having as precise antecedent conditions as have the most familiar facts in the material or mechanical world. We are assured, also, that simple observation and analogy, are ways of study, not less pregnant than are experiment and exact analysis. Short of attempting to grasp the fundamental molecular "form" of phthisis in its failure of the correlated mode of vital "energy" at certain ages, and in certain individuals, the most seemingly wide common general phenomena are those of heredity and atavism. (a) We may sometimes almost predicate that certain young men and women will die early of phthisis, whose parents may be robust and beyond middle life, if they have uncles and aunts, &c., of certain physical type.

What are these types, in direct or collateral relations, which are most commonly associated with phthisis in descendants? I have no doubt that observers will find a large proportion have the region including the optic foramina and root of nose unduly sunken. A very striking fact which is being frequently presented is that, in parents, or uncles, or aunts, the nose is unduly out of the mesial line; the eye-brows are often massive and meet in the mesial line; there is often a vast growth of hair on the scalp; there are those with extreme delicacy of hands and nails, and others with the large broad cold hands.

(To be continued.)

Clinical Records.

GLASGOW ROYAL INFIRMARY.

Case of Urethrotomy for Chronic Cystitis.

By JAMES MORTON, M.D.,

Surgeon to, and Lecturer on Clinical Surgery in, the Royal Infirmary.

JOHN GOLDIE, æt. 38, a miner, had been in Ward 19 of the Glasgow Royal Infirmary during the early part of the year 1883, suffering from chronic cystitis, and was re-admitted on 22nd November of the same year, still suffering from the same malady. Frequency and pain in micturition are his chief complaints, always present, but aggravated after a full meal. He is compelled to urinate once every hour or oftener, both day and night, and has become much emaciated and anæmic from want of sleep. The urine is cloudy; contains urates; sp. gr., 1010; no albumen.

Dec. 7th.—To-day patient was placed in the lithotomy position, a staff introduced, and the membranous portion of the urethra was opened from the perineum, and the finger insinuated into the bladder, gently dilating the prostatic portion and neck of the bladder. A lithotomy tube was introduced to keep the wound open and allow the urine to drain off, and give rest to the bladder.

On the 9th the tube was taken out, but it was found that frequent urination at night recurred, and on the 10th a catheter (elastic) was introduced through incision, and tied in. This was continued till the 26th December, when the catheter, having accidentally come out, was allowed to remain so till the 28th, when a tube was re-introduced, as the man complained of pain and uneasiness. About this time the patient began to introduce the tube for himself at night, and to take it out in the morning, thus obtaining undisturbed nights, and on the night of January 14th, 1884, he was unable to introduce it, as the wound had now contracted very much, and was very small. He was, therefore, allowed to discontinue the use of the tube. He can retain his water

(a) In seeking to estimate the relative value of phenomena in any side of nature, we have to carefully remember what Bacon says: "The nature of the human mind is more affected by affirmatives and actives than by negatives and privatives, whereas by right it should be indifferently disposed towards both. But now a few times hitting or presence produces a much stronger impression on the mind than many times failing or absence: a thing which is as the root of all vain superstition and credulity."—"De Argumtis," 6th book, page 452, vol. IV., 1858. Spedding's, Ed.

for two hours, and on the 19th January he is said to be able to retain his urine for two and a-half or three hours, and was then dismissed.

Remarks.—This case belongs to a class for which, till lately, very little good was done by the ordinary treatment, and to Sir Henry Thompson the profession is indebted for suggesting and introducing the operation which has been found to benefit such. The object of the proceeding is the very laudable, though very common, one of giving rest to the diseased and suffering organ, so as to allow it to undergo repair, and certainly the benefit in this case was very marked. The operation in competent hands is easy, and unattended by any great risk, either at the time or afterwards. It seems to be adapted to those cases of chronic cystitis in which there is no reason to believe that other organs are the seats of disease. In almost all such cases some albumen in the urine may be expected, but, if it be small in quantity, it is probable that the bladder is the sole cause of it; the kidneys most likely are sound, and it follows that early operation may have something to do in anticipating or preventing those secondary changes in the kidneys which are the well-known sequelæ of diseases of other parts of the urinary apparatus. The case itself has taught me, and may teach others, that several weeks are required to allow all the benefits of the operation to be experienced by the patient himself, and the sensitive interior of his vesica or bladder. Not the least pleasing feature in this man's case was the thoroughness with which he appreciated the relief aimed at and attained, and the readiness with which he undertook the evening introduction of the catheter or tube, so as to secure his night's rest undisturbed by urgent calls to void urine from a hyper-sensitive viscous. After the operation, no medication of the interior of the bladder was attempted, and it has proved unnecessary.

France.

[FROM OUR SPECIAL CORRESPONDENT.]

THE meeting of the Académie de Médecine was occupied all day with a discussion on the ingestion of alcohol and its effects in the economy.

ANEURISM.—M. Trélat communicated two cases of aneurism to the Société de Chirurgie, one of which refused to be influenced by indirect pressure sustained a relatively long period. The position occupied by the tumour was the popliteal space, and although compression was made in Scarpa's triangle no diminution was appreciable. At last the ligature was resorted to, and tumour was not slow to shrink, harden, and disappear. The same member reported a case of suture of the perineum, in which the perineal and vaginal suture were made. The patient cured rapidly. Out of eleven cases thus operated upon only three failed. M. Verneuil, who agreed with M. Trélat as to the position of the sutures, preferred the silver wire to the mother of pearl buttons; he leaves them eight or ten days *in situ*. M. Després was astonished at the large number of these cases which have recently come to light. In his long career he had only three times practised the operation. His principle was to wait until three months after the delivery, and to prevent the vaginal liquids from penetrating the wound he made the patient lie on her face. M. Thomas communicated the case of an irreducible prolapsus of the uterus, and for which he was compelled to have recourse to total ablation by the elastic ligature. It was the case of a domestic who, for two years, had been suffering from the affection in question, and all attempts at reduction were rendered useless. The tumour was voluminous and showed signs of sphacelating. In an attempt at reduction he tore the posterior wall of the vagina. It was then he decided on extirpation, and the patient made a good recovery.

CASE OF HYSTERIA IN A MAN.—At the Société des

Hopitaux M. Debore made observations on a case of hysteria in a man who recently came under his notice. The individual was brought to the hospital in an unconscious state, and on examination hemiplegia of the left side was discovered. Syphilis was supposed to be the cause and in two months he left the hospital cured. A month ago the patient fell into the same state, and the hemiplegia this time was accompanied by anæsthesia and contraction of the same side. At the time of speaking the paralysis has nearly disappeared, but he is still hæmianæsthetic. On pressing over the region corresponding to the ovary in woman a pain is produced similar to that observed in the hysteria of the opposite sex, and M. Debore considered that this fact would prove that the ovary in woman had very little to do with hysteria. M. Jouffroy had seen an hysterical man who presented a tenderness in the iliac region, and he was of opinion that in woman it was not so much the ovary itself which produced the pain as the plexus of nerves by which it was surrounded, and that the same plexus could be found in man.

DAMAGES FOR MALPRAXIS.—The Court of Nimes has just condemned a doctor to pay £70 damages and a yearly sum of £8 to one of his patients whom he grossly neglected. Our *confrère* was called to attend a young woman, æt. 30, for a dislocation of the elbow without fracture. The reduction was effected very promptly, and a bandage placed above and below the joint. The bandage was so tightened that it caused excruciating agony and the patient supplicated her medical attendant four consecutive times to loosen it, but he turned a deaf ear to her entreaties. After thirty-six hours suffering another doctor was called in who found that already gangrene had set in in the hand and lower part of the forearm. The result was, the patient lost the use of her arm and was obliged to give up her profession which was that of *modiste*. Three expert medical men were called from Montpellier in favour of the plaintiff, and all agreed in saying that their *confrère* was greatly to blame in refusing to loosen the bandage. The plaintiff had claimed £1,200 damages.

Special Articles.

MIRYACHIT.

In the February number of the *Æsculapian*, Hammond, of New York, brings under the notice of the profession an affection of the nervous system said to be common in Siberia, particularly about Yakutsh, where the winter cold is extreme, and called by the Russians Miryachit. Essentially this affection consists of a forced imitation of any sounds uttered suddenly in the patient's hearing, or of any acts suddenly performed in his presence. Thus, if a man claps his hands before the face of a sufferer, the latter will immediately imitate the action precisely—against his will, and even though he is annoyed at the liberty. Similarly, a sudden whistle or shout is exactly imitated. The patient will even fall with some violence in accurate imitation of a person whom he sees falling suddenly. From the short description given, it would appear necessary that there should be some degree of suddenness in the presentation of the sensation in order to call forth the mimetic action. Both sexes are attacked by miryachit, but women more frequently than men. Hammond points out the analogy between this condition and that of the jumpers of Maine described by Beard, but the jumpers obeyed commands involuntarily and most irrationally, and thereby seem to have incurred sufferings which the happier Russians were spared. The name of jumpers appears to have arisen partly because the unfortunate victims of the ailment

that Beard describes were made to jump "to order,"—partly, also, because they always jumped violently on hearing a sudden noise. The jumpers repeated involuntarily commands given them in a loud voice, and even sentences in languages which they were not acquainted with. Hammond further compares the affection he describes with the phenomena of the State, called by the Germans *schlaftrunkenheit*, but the resemblance does not appear to be close. There is a much closer analogy to some forms of the hypnotic state. The variety of hypnosis, so familiar to the practitioners of "electrobiology," is characterised both by tendency to imitation and by obedience to command. Here, however, there is unconsciousness. But Heidenhain has demonstrated in unilateral hypnosis, in which consciousness is retained, a tendency to forced imitation in the movements of the side that has not been hypnotised, and that remains perfectly movable. This tendency can be overcome by an effort of the will. There are also cases of total hypnosis in which consciousness is retained, and forced movements of imitation occur. Such cases would seem precisely analogous to miryachit, and it is somewhat singular that Hammond has not mentioned them in this connection.

Should the description of the "newly-described nervous affection" prevalent in Yakutsh be verified by careful observers, it will go far to sweep away Heidenhain's explanation of hypnosis as a result of inhibition of the action of the higher nervous centres. For here there is no previous irritation to bring about the inhibitory action, the condition appears chronic, and it would either look as though the impressions received from the senses were translated at once into motor impulses through a failure of the normal inhibitory action of the higher centres, similar, or comparable to that which occurs when reflex action is exaggerated in consequence of sclerosis existing in the motor tracts.

Sanitary Department.

DR. BARRY'S REPORT UPON THE TYNEMOUTH DISTRICT. (a)

THE important and elaborate inquiry recently carried out by Dr. Barry, on behalf of the Local Government Board, into the sanitary circumstances of the above district owed its origin to the prevalence of Scarlatina and other zymotic diseases.

The older houses in the colliery villages were found to be damp and badly ventilated, and in many cases all those of a row communicated with each other. The water-supply was liable to pollution, being derived from surface wells. No provision was made for excrement disposal, the males resorting to the fields, and the others mixing their dejecta with the house refuse, which is deposited on the roadside. Others, however, had been found more or less improved in recent years. The modern colliery houses, again, showed a still greater advance in sanitary excellence, being of ample cubic space, well ventilated, and furnished with damp courses. The water was derived usually from the nearest coal-pit, and was piped to stand-pipes, from which houses are often distant 750 yards. Excrement and refuse, however, were disposed of throughout the district in midden privies, which were arched and usually blocked up, besides the contents being exposed to mixture with rain water, and consequent rapid decomposition; the removal of this refuse was also incomplete, a "soft core" being left. Dr. Barry advises the

(a) To be purchased of Knight & Co., Shaw & Sons, Hadden & Co., and King & Sons.

pail-closet system, and separation of the contents of the pails from ashes, &c.; he also suggests several provisional alterations in the existing middens. The main conditions that he found influencing the spread of infectious diseases in the district were (1) arrangement of houses in rows; (2) mingling of healthy and infected at stand-pipes; (3) drainage by open channels; (4) storage of excrement and leaving of "soft core;" (5) the often temporary character of the water-supply; and (6) want of means of isolating the sick. To these might be added, the habit of visiting friends, and of helping in sickness.

Dealing with the mortality statistics of the district during 1873-82, Dr. Barry finds the mean general death-rate, the scarlatinal death-rate, and the infant mortality above the average of England and Wales, whilst that of Small-pox was much lower. (The zymotic rate is also seen to be slightly higher.) The mortality from "Fever" had decreased progressively throughout the district. The mean Scarlatinal mortality was excessive in the Tyneside districts, and in Blyth, Cowpen, and Seghill urban districts. Further, the high fatality from infectious diseases was usually associated with high infant mortality. The inspector next proceeds to deal with each disease separately. Thus, Scarlatina prevailed epidemically every 5 or 6 years, the mean mortality being double that of England and Wales, and the total death-rate under 5 years as high as 79·6 per 10,000 living at those ages. He accounts for the periodicity of the disease by the re-accumulation of children at the susceptible ages. A direct connection is traced between degree of fatality on the one hand, and density of house population and the sanitary influences affecting the general death-rate on the other. The reasons that account for this great prevalence are personal intercourse (which is intensified by the construction of the villages), and want of isolation; further opportunities are afforded by congregation at the stand-pipes, and exposure (often purposive) of children during desquamation. Next, as to small-pox, the mortality from which was far below the average. This Dr. Barry ascribes to the enforcement of the Vaccination Act of 1871 by the several guardians of the district, since prior to 1873 fatal cases had been registered yearly. With respect to Enteric fever, the rate of mortality from which had progressively decreased, this decrease was most marked where pollution of soil, air and water was least. An outbreak in Burradon and Hazelrigge was investigated, and ascribed to the pollution of a certain well used by the majority of the persons attacked by the contents of a foul open ditch, into which the refuse from the early cases had been admitted. Infant mortality, which in the district exceeded that of the whole county, is ascribed to wrong feeding, exposure, and scarcity of milk, the latter being obviated in some places by the establishment of a dairy.

Dr. Barry concludes his able report by recommending the amalgamation and combination of certain sanitary districts, the provision of hospital accommodation for isolation of early cases of infectious disease (at the rate of one bed per 1,000 of population), and points out the unsatisfactory nature of the existing building bye-laws. Several plans and tables are appended.

THE GORE FARM SMALL-POX TENT HOSPITAL.

Owing to the recent exacerbation of small-pox prevalence in the East of London, and the consequent filling of the Hospital ship *Atlas*, the Metropolitan Asylums Board have been obliged to institute a tent hospital for convalescents from that disease upon part of the Gore Farm estate recently purchased by them. This has been placed on the side of a hill, at a

distance of 1,000 feet from the Darenth Asylum, separated by neutral ground from the road, and consists altogether of 20 marquees for sleeping, 2 for day use, besides tents for officers, &c. The sleeping tents accommodate 20 patients, are 50 feet apart, and in 2 rows 80 feet distant from each other; their floors are wooden, raised on brick piers; each is provided with a Moule's earth closet, is warmed with steam and lighted with gas. There is an elaborate bath-house containing 24 baths, the waste-pipes of which discharge externally over open traps. A large, well-fitted and suitable kitchen is provided. Disinfection is performed in a room furnished with Lyon's apparatus. The important matter of laundry administration is carried out by the setting apart and isolation of a portion of the Imbecile Asylum's laundry for the purpose; soiled linen is disinfected (how, is not stated), before being taken there in a closed tank. The method of discharging patients is complete in detail, and leaves nothing to be desired in the matter of avoidance of the carriage of infection. The water-supply has been effected by extending the main across the Asylum grounds through the Hospital to large storing tanks, from which it is laid on to sinks, baths, &c. Steam is supplied to each tent from two multi-tubular boilers specially provided; gas from the asylum works. Besides the earth closet for night use, 14 other Moule's have been placed in the grounds for day use; the earth is dried in a special furnace and the soil buried. Waste water and slops, are, however, dealt with by sub-irrigation.

We must congratulate the Asylums Board and their architects (Messrs. Harston) on the successful nature of the provision they have made for the isolation of small-pox convalescents.

Transactions of Societies.

CLINICAL SOCIETY OF LONDON.

FRIDAY, MAY 9TH.

The President, ANDREW CLARK, Bart., M.D., in the Chair.

Mr. CLUTTON on a case of

INTESTINAL OBSTRUCTION (BY A DIVERTICULUM) SUCCESSFULLY TREATED BY OPERATION.

A boy, *æt.* 10, was brought to Mr. Clutton's notice by Dr. Powis, of Greenwich. He had had several other attacks of a similar kind, but lasting only two or three days, and always terminating with a copious evacuation from the bowels after enemata. On this occasion he was taken ill suddenly at the seaside with vomiting, and great pain in abdomen. He was brought home to Greenwich on the third day, and as treatment by enemata and opium proved of no avail, Mr. Clutton was asked by Dr. Powis on the fourth day of the illness if operation would be likely to afford him relief. He was at once transferred to St. Thomas's Home, where, after the administration of an anæsthetic, the abdomen was opened. A collapsed portion of bowel was soon found, and on bringing it to the surface a tight ring-like cord could be felt and seen to be the cause of strangulation. This band was clamped by two pairs of forceps and divided, each end was then ligatured with catgut and the forceps removed. The bowel was found after the division of the constricting band to have been set free from strangulation. It was not thought desirable to make more than a cursory examination for the origin of the band causing the obstruction as the boy was much collapsed before the operation commenced. The two catgut ligatures formed the means of recognising the original position of the now divided band. One of these ligatures was situated at the extreme point of a diverticulum two inches in length, and the other was placed upon the wall of the same loop of intestine at a distance of about six inches. A portion of bowel of about three inches in length between these two points of attachment was the part strangulated, and was of

an extremely dark colour with a deep sulcus at each side. The boy made an uninterrupted recovery and left the hospital on September 12th. The explanation of the condition found in the abdomen seemed to Mr. Clutton to be as follows:—The vitelline duct had been obliterated at the umbilicus, and set free from the abdominal wall, but remaining patent toward the ileum the lower end had become a pouch-like diverticulum from the intestine. This diverticulum terminating in a pointed extremity or cord—part also of the vitelline duct which had been obliterated—had remained floating about among the intestines till it became attached, as we have seen, to the bowel in contact with it. The gut between the two points of attachment had slipped beneath the cord which united them, and being unable to extricate itself had become strangulated.

Dr. COUPLAND said that no instance of recovery had occurred in any of the several cases of this nature he had seen operated on. It was probably owing to the prompt interference that Mr. Clutton's success was due. The form of strangulation met with in this case seemed that most commonly encountered, and on the post-mortem table he had seen more than one example of unrelieved Meckel's diverticulum. In one instance especially, a man who during life complained of pain in the intestinal region, and whose umbilicus was depressed, the diverticulum had never become free, and was attached at the umbilicus. Possibly the umbilical symptoms might aid diagnosis. In another case, a boy, under Dr. Greenhalgh, and which was not operated on, there was found, *post mortem*, a strangulated coil of ileum passing through a mesenteric diverticulum, the dimensions of which much exceeded the natural limits of such openings.

Mr. TREVES congratulated Mr. Clutton on the good success he had obtained, and mentioned that of the twenty-nine cases collected by Perrot, but seven recovered, while of the four patients in whom the strangulation was associated with Meckel's diverticulum but one survived operation. As a result of his own researches, Mr. Treves had found that eight recoveries occurred out of thirty cases, and he inclined to think that even this mortality would be much increased did surgeons report all unsuccessful cases. As a rule, death took place on the fourth day, and it was necessary to remember that as well as the strangulated intestine the strangulating agent shared in damage done to nervous and vascular structures. The diverticulum was attached to the free end of the mesentery in twenty-five out of fifty cases collected by himself. It would have added to the value of Mr. Clutton's paper had it contained more of detail in relation to the clinical history of the case. A history of previous attacks was of no particular importance, since but twelve per cent. afforded any such history. Except in cases of complete strangulation, pain would be intermittent in character, not continuous, as in those where strangulation was complete. The seat of pain would not afford a clue as to the site of strangulation, because in most instances it occurred at the umbilicus or in deeper situations difficult of localisation by the patient. Mr. Clutton's was the first case in this country in which recovery had taken place.

Dr. MAHOMED was convinced that paroxysmal pain might be present also in complete obstruction of the intestine, his own experience of nine or ten cases having led him to this conclusion. Was it possible that in cases of extreme distension the obstruction would be found always in the large intestine? This had an important relation in connection with relief by colotomy. Dr. Mahomed concluded by urging reasons why the site selected for operation in all cases should be on the outer side of the right rectus muscle.

Mr. TREVES explained that he did not wish to convey that there was an absence of pain in incomplete cases of strangulation. His reference was to its continuous nature in the one class, and paroxysmal in the other.

Mr. SYMONDS thought more information was to be desired respecting the spot selected for incision. In this connection his opinion was not in agreement with that of Dr. Mahomed. As a rule, the most prominent part should be chosen, as in the two cases he had most recently seen, both, however, fatal. He approved of the middle line as the situation for the incision, because it afforded access to all parts likely to be involved. The excessive mortality among these cases in hospital practice might be explained on the ground that they were subjected to a deferred treatment until their nature had been fully understood.

Mr. H. MORRIS quoted a case in which operation by the median incision had been performed immediately after admission of the patient—a subject of old double hernia—into hospital. On the left side a knuckle of small intestine had been displaced by the hernial sac, the neck of which was divided, and the strangulation thereby relieved. Diarrhoea came on, and death occurred thirty-six hours after. *Post mortem*, the large intestine was found obstructed, the cæcum largely distended, and perforated. Right-sided colotomy might be employed at first in doubtful cases, and subsequently the median operation, if necessary. In one case of this nature in which this course was followed, it was found after death that the small intestine was the seat of obstruction, although relief was afforded by evacuation of a distended large intestine as a result of the colotomy.

Mr. CLUTTON said his patient experienced exacerbations followed by lulls, during one of which operation was performed, it being deemed unwise to wait for recurrence of urgent symptoms. As a proof that some fatal cases survive the fourth day, he mentioned one in which death occurred on the ninth day; it was not operated on. On every ground Mr. Clutton approved the selection of the mid-line as the place of operation.

Mr. CHRISTOPHER HEATH ON

THE TREATMENT OF FRACTURED PATELLA,

in fulfilment of his promise at an earlier meeting of the society, to produce patients treated immediately after the accident by plaster-of-paris. He gave Mr. Hutchinson the credit of first combatting the old teaching that separation of the fragments depended on muscular action, and agreed with him in believing that it was the fluid in the joint which was the difficulty. Mr. Heath gets rid of the fluid by aspiration, and has never seen any bad result from the practice, but prefers, when possible, to prevent effusion by at once enclosing the joint in plaster-of-paris. This requires renewal in about six weeks, and at the end of three months a leathern splint is applied to the knee and thigh so as to control the action of the extensor when the patient is walking. Two women and a man were shown, in all of whom the plaster was applied within an hour of the accident with very good results as to short fibrous union.

Mr. MORRIS exhibited two cases treated since Sir Joseph Lister's address, both men. In one the fracture was high, the upper third of the patella being broken off and dragged up in the thigh, but being subsequently "kneaded" down by the patient himself. This showed, Mr. Morris thought, that retraction by the muscle does occur. Displacement, however, was influenced by laceration of the fibrous investing capsule, as had been proved by experiments on the cadaver. Tearing of the capsule might easily attend the application of such muscular force as sufficed to bring about the fracture. The treatment adopted was primary extension by a special form of splint and strapping; and subsequently an apparatus was worn which permitted of gradually increasing flexion of the joint, the patients meanwhile pursuing their usual callings.

Dr. ALTHAUS inquired if the patellar tendon reflex existed in these cases, and on the suggestion of the President he proceeded to examine the patient exhibited with the view of determining the point. At a later period of the meeting Dr. Althaus reported that the reflex phenomenon was present in equal degree on both sides.

Mr. PARKER observed that effusion would prevent approximation of the fragments, whatever agency might originally separate them. Aspiration of the joint had been formerly denounced at the Surgical Society of Paris.

Mr. SYMONDS asked what quantity of fluid Mr. Heath had withdrawn by aspiration. Was two drachms a satisfactory amount to remove? He had recently treated these cases of fractured patella by immediate compression with Martin's rubber bandage, and followed this by application of plaster-of-paris. In three weeks' time the patients were about with good and useful limbs.

Mr. TURNER contended that the results obtained by Sir Joseph Lister were better even than that exhibited by Mr. Morris. He had found bony union to have taken place in a patella treated by wiring. The specimen was in King's College Museum. He was unaware of a similar result obtained by any other mode of treatment. With an intact capsule patients might possess the power of moving the leg usefully, notwithstanding fracture of the patella with no union, but separation of the fragments. The success of the cases shown could not be properly estimated so early after recovery. In

one case treated by Malgaigne's hooks three inches of space separated the fragments after six months. Wiring was subsequently resorted to with the best possible result.

Mr. GODLEE remarked that advocates of treatment by wiring contended that this mode of treatment alone yielded perfect results, notwithstanding other methods also gave good results. On the other hand, opponents of the practice denied that any justification for opening the joint could be found.

Mr. HEATH expressed himself unconvinced by Mr. Morris's case in proof of the fallacy of Mr. Hutchinson's theory that it was not muscular force which kept the fragments apart. The fact that Mr. Morris's patient was able to bring down the retracted fragment showed how brief the muscular spasm was. He (Mr. Heath) had removed as much as 3 or 4 drachms of fluid by aspiration. Now, however, this practice was rarely resorted to, all patients being treated by immediate application of plaster-of-paris on admission. He promised to keep his cases in view, for the purpose of testing the permanency of cure.

Dr. WHIPHAM brought before the Society a case of HYDROCEPHALUS, PROBABLY OF OLD STANDING, FOLLOWED BY INSANITY AND DEATH.

The patient, *æt.* 39, was one of twins, his brother having died in infancy of effusion on the brain. In early years the subject of the communication had been uncertain in temper, and had occasionally squinted. After 12 years of age he enjoyed remarkably good health; his intellectual capacity was above the average; he was well informed on most subjects, and fond of exercise. He had suffered in early manhood from a soft sore, but never had syphilis. On October 7th, 1882, he consulted Dr. Whipham, because "he had been mad." It then appeared from inquiries through his wife and friends that he had been for eighteen months from time to time strange in manner and irritable, and that he often sat by himself at his club muttering; that in conversation he often lost the thread of his discourse; that he had written inexplicable letters to a relative and to a friend. Of late he had become very drowsy, and even went to sleep occasionally while at meals. His memory had been failing for eight months or so. He had been a regular, but not excessive, smoker. At the date above mentioned his expression of face was vacant, and, unless questioned, he stared vacantly at space. His answers were inaccurate, and he had one or two delusions. His gait was steady, his grasp feeble, his special senses natural. He became more and more capacious and irritable, and his usual reading was distasteful. Once or twice he was obstinate and somewhat violent in the streets. By Dr. Blandford's advice, he went to Folkestone for change, but derived no marked benefit. On one occasion he started for a walk by himself in the middle of the day, and returned without being able to give any account of himself until nearly midnight. On his return he became morose and sullen rather than violent, and was eventually sent to Munster House. Soon after his arrival it was noticed one day that the left pupil was larger than the right, and he had a fit during dinner. Ten days later he was again violent and noisy, wet and dirty. Two days before his death, when walking with the support of an attendant, he suddenly fell headlong to the ground, sustaining no injury save an abrasion of the nose. The patient died early on December 28, 1882, and on the morning of the previous day had been excited and very noisy. Subsequently he became unconscious for some hours. At 7.30 p.m. he recovered, and was more rational than at any time since Oct. 10. This condition lasted for a quarter of an hour, when he again became drowsy, and at last unconscious till his death. At the autopsy the ventricles of the brain were so distended as to contain about $\frac{3}{4}$ -pint of fluid. The dura mater was adherent generally to the skull-cap. No other lesion of the brain was found. Dr. Blandford, who was called in consultation, rather inclined to the diagnosis of general paralysis, basing his opinion on the elation, incoherence of ideas, and inability to concentrate his attention. Dr. Savage, in the *Journal of Mental Science*, July, 1880, records a case in which great dilatation of the ventricles was found in a female, *æt.* 35, who was insane for eight months before her death. In this case, however, there was the complication of granular kidneys. In the case before the Society all the symptoms of general paralysis were not present, and a certain diagnosis was not made. Elation certainly existed at one time, but only lasted for a day or two, and the gait, save on one or two occasions soon after the attack, was remarkably steady. In the absence of any evidence of other disease, the symptoms must be referred to the hydrocephalus, presumably of long standing.

Dr. BLANDFORD said he had seen the case on two occasions. Though anomalous in many respects, yet it seemed to promise to become one of general paralysis. He had anticipated maniacal outbreaks after admission into asylum, but instead of this the patient fell into a comatose condition, and could be roused out of it only with difficulty. It was curious that a sensible interval preceded death. The case was a difficult one in many ways, and deeply interesting.

Dr. ALTHAUS asked if there was any history of syphilis? to which

Dr. WHIPHAM replied in the negative; as also to a question from Mr. Parker respecting the existence of notes on the condition of the choroids.

Living specimens of rupture of the brachial plexus (two cases) were exhibited by Mr. Symonds and Mr. Davies Colley; and two cases of fractured patella (recovery) by Mr. H. Morris.

ODONTOLOGICAL SOCIETY OF GREAT BRITAIN

MONDAY, APRIL 7TH.

J. SMITH TURNER, M.R.C.S. and L.D.S. Eng., President, in the chair.

REPLACEMENT OF DISLOCATED TEETH.

Dr. BELLISARIO, of Sydney, New South Wales, read notes of the case of a gentleman, *æt.* 27, who was thrown out of a dogcart, striking his face against the stump of a tree. Three of the upper incisors were displaced, and the fourth broken across transversely; the lower fragment could be moved about in any direction, though with great pain to the patient, and crepitus could be distinctly felt. The displaced teeth were brought into proper position, and a thin gag inserted between the molar teeth; only liquid nourishment was taken for several weeks. In the result, not only did the dislocated teeth become fixed, but the fractured incisor also united firmly, and at the end of three months all four were as strong and useful as before the accident, and quite natural in appearance and in sensibility.

Mr. ARTHUR UNDERWOOD read a paper on THE INFLUENCE OF MICRO-ORGANISMS IN THE PRODUCTION OF DENTAL CARIES.

He referred to a paper read before the Dental Section at the International Medical Congress in 1881, in which he had shown that certain forms of micro-organisms were invariably present in carious dentine; that no change resembling caries could be produced in the absence of these organisms, i.e., under aseptic conditions; and that under septic conditions a change could be produced artificially which, if not undistinguishable from ordinary caries, certainly resembled it. The fact that organisms were invariably present had since been confirmed by numerous observers. It had been stated by one investigator, Dr. Miller, of Berlin, that the dentine was first softened by acid, the invasion of the micro-organisms being only secondary to this, and that a zone of softened dentine not infected with organisms always existed in advance of that which was so infected. He and his colleague Mr. Milles had on the contrary found that the organisms extended as far as the softening; they could not find any softened tissue which did not contain micro-organisms, and they were of opinion that the acid which softened the dentine was produced by the organisms, just as occurred in ordinary processes of acid fermentation. They had cultivated the various organisms found in carious dentine in flasks containing purified blood serum, after the method introduced by Professor Koch, and had ascertained that there were several distinct varieties, but experiments made with the view of finding out which of these species were the most active agents gave negative results. Dr. Miller had stated that he had produced artificially out of the mouth caries which he defied anyone to distinguish from that which occurred in the mouth. Messrs. Underwood and Milles had repeated his experiments, and had tried several of their own with but very partial success; the result was that in the absence of germs no change takes place which could be supposed to be caries; in the presence of germs a change does take place resembling caries, but which invariably became arrested before it had gone very far. This comparative failure was no doubt caused by the difficulty of assembling in a flask or incubator experiment all the various conditions

which were present in the mouth, and instances were quoted from the experiments of Koch, Pasteur, and Nægali to show that micro-organisms cultivated under conditions not altogether favourable became weakened, and even lost their special attributes, so that the bacillus of anthrax, for instance, could be inoculated harmlessly. The authors of the paper claimed to have established that micro-organisms of a special form were an essential element in the production of dental caries. Food gets lodged between the teeth, and undergoes fermentation, with formation of acid and bacteria; the acid destroys the enamel, the micro-organisms invade the dentine, proliferating in the tubes and living at the expense of their organic material, their advance being accompanied by decalcification of the intertubular substance.

A discussion followed, the tone of which was distinctly favourable to the adoption of the views promulgated by Messrs. Underwood and Milles. It was remarked that these cleared up some points which the purely chemical theory of caries did not explain, *e.g.*, the fact that the dentine was destroyed more rapidly than the enamel, and a hope was expressed that the discrepancies at present existing between the results arrived at by Messrs. Underwood and Milles and by Dr. Miller might soon be settled by the testimony of independent investigators.

THE MEDICO-PSYCHOLOGICAL ASSOCIATION.

THE quarterly meeting of this Association was held at Bethlem Hospital on Tuesday, the 6th May,

Dr. ORANGE, President, in the chair.

A letter was read from Dr. Manley, the President-elect for the ensuing year, announcing his inability, through ill-health, to fulfil the office to which he was elected at the last annual meeting. A resolution of regret and condolence having been duly passed, the President stated that, acting under the Association's rule providing for such emergency, the council had exercised the duty imposed upon them by electing Dr. Rayner to act as President during the coming year. Papers were read by Dr. Hayes, Newington, on "Unverified Prognosis," and by Dr. Bonville Fox, on "Exaltation in Chronic Alcoholism," and Dr. Mercier introduced resolutions in favour of the transference of lunatics of foreign nationality to their own countries.

A SERIOUS epidemic of scarlatina has broken out at Waterford, and last week there were nearly one hundred patients in hospital suffering from the disease.

By the death of Mr. King, a well-known dealer in works of art in London, the magnificent legacy of £100,000 falls to the treasury of St. George's Hospital, Hyde Park. The remainder of deceased's wealth, amounting to an even greater sum, is, we understand, bequeathed to his friend and medical adviser, Dr. Roper.

By the will of the late Mr. William Foster, of Hornby Castle, the Bradford Infirmary receives £1,000 to the endowment account and £500 to the building account; the Bradford Fever Hospital, £750; Bradford Eye and Ear Hospital, £250; Bradford Children's Hospital, £500; and Halifax Infirmary, £1,000.

BRIGADE-SURGEON E. G. MACDOWELL, of the Army Medical Department, who acted as principal medical officer to the late Soudan Field Force, has been granted special leave of absence from Cairo to England till September 3 next. He will, it is stated, be shortly created a Companion of the Order of the Bath for his services in the recent campaign.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, MAY 14, 1884.

THE INTERNATIONAL HEALTH EXHIBITION.

ON Thursday last the magnificent and extensive Exhibition which has so long been in preparation at South Kensington was duly opened to the public; and, judging from the numbers who availed themselves of the first opportunity of examining the collected treasures there displayed, there can be no question of the very general interest excited by it in the public mind. The inauguration ceremony was performed by the Duke of Cambridge, whose first duty was to listen to a tediously and unnecessarily lengthy address from the Duke of Buckingham, Chairman of the Exhibition Committee. On the conclusion of this part of the programme, H.R.H. the Duke of Cambridge made a commendably brief reply, and concluded by declaring the Exhibition duly open. There was ample evidence, even at this period of its existence, that success was destined to attend the efforts of the originators of the affair, for already the courts and galleries of the Exhibition building were crowded with visitors; and as the day advanced the throng grew yet more dense, the evening especially presenting a most busy and animated scene.

It is not to be expected that the arrangement of the Exhibition could be completed in time for its inauguration; but, nevertheless, a surprising advance had been made in this direction during the few days immediately preceding the opening; and even now there is abundant material to engage the attention of even the most *dilettante* visitor for many hours, while special attractions

in the way of outdoor concerts, &c., exist to satisfy those who prefer to temper instruction with pleasure.

The object of the Exhibition being, above all, to advance the sanitary welfare of the people, advantage has been taken of every form and description of exhibit possessing the slightest bearing in this direction. For this reason, therefore, some things have been included which at first sight seem hardly to have reference to the specific purpose of the display; but even these can fairly be shown to have a definite connection with health—such as, for instance, cigars, tobacco, and smoking appliances; stuffed fowls, and other birds used as food; Indian mats, and other Oriental furniture, &c., &c. In the section of the Exhibition devoted to foods and manufactures of foods, there is shown a collection of exhibits such as has never before been arranged under one roof; and the visitor cannot fail to be impressed with the marvellous completeness of the show in this respect. Not only are the articles themselves to be seen, but every stage in the manufacture of them is carried on before the eyes of the spectator, costly and extensive machinery having been laid down for this purpose, and presenting such an appearance of solid permanency that it is difficult to believe the whole is but a temporary arrangement for exhibition purposes. In the same way, too, a number of dairies have been erected and fitted with the utmost fidelity in matters of detail; and every process, from the milking of cows to the production of butter and cheese, is systematically carried on by staffs of attendants, who appear to pursue their labours with an utter indifference to the fact that they do so in the full gaze of thousands of deeply-interested inspectors of the various operations. Already, indeed, it is clear, by the persistence with which the part of the Exhibition devoted to industrial occupations is daily patronised by large numbers, that this department adds largely to the popularity of the whole; and we cannot hesitate to congratulate the authorities on the complete success of the measures they have taken with regard to it.

The department of pharmacy is well represented by collections of drugs and preparations, contributed by firms of world-wide reputation in this connection, and to which we shall refer in detail when dealing with the exhibits in a series of special articles which will be published from time to time in our pages.

House construction and sanitation very naturally constitutes a prominent and highly important section of the Exhibition; and perhaps the most interesting, and certainly the most striking and picturesque object shown in the whole vast collection, is a reproduction of part of ancient Cheapside as it appeared previous to the fire of 1666. The conception of this addition to the Exhibition was most happy; and the Council are to be deservedly congratulated on the liberality with which the ideas of the artist have been carried out in its fulfilment. The appearance presented by this building is most striking, the houses themselves being so cunningly built and painted that it is extremely difficult when viewing them from without to convince oneself that the whole is nothing more than a reproduction, and is not the actual thing it pretends to be. As yet, the interiors remain uncompleted, and the newness of all within

offers a striking contrast to the ancient external. Shortly, however, this will be remedied by fittings which will transform the rooms and passages of the houses to a condition as worthy of their pretended age as that which obtains on the outside; and then, it is certain that a valuable lesson will be drawn from comparison of these remnants of older London with some of the model dwellings, of which several have been built in adjacent parts of the Exhibition. But, however unsanitary the arrangements of Cheapside may be ultimately represented to be, we shall still regard the quaint old houses with an unabated feeling of affection, while nothing in this way can possibly detract from the admiration felt for the beautiful picture it presents in an artistic sense. Even the large sum—exceeding £11,000—spent in its production is well repaid by its final effect on the mind of the spectator.

The profusion of exhibits of sanitary appliances is absolutely bewildering at first sight; and were it not for the admirable assistance lent by the official catalogue, any orderly arrangement of ideas on the value of this section would scarcely be possible. There is, however, enough and more than enough to educate the most unlearned of the public as to the importance of hygienic home surroundings; and with a little attention even, he may speedily become aware, by actual demonstration, of the principles on which a healthy dwelling ought to be arranged. In an educational sense, this section is likely to have an important influence, by teaching even casual visitors to appreciate the meaning of drainage and ventilation; and by exciting uneasiness concerning, and an ultimate desire to remedy, errors of construction in the houses of those who will have learnt for the first time what are the practical bearings of hygienic engineering. The appliances shown in this connection will, however, engage our future attention in detail.

Of the other departments of the Exhibition it is impossible, in a general article, to speak particularly. They are numerous, and in every case absorbingly interesting; especially that devoted to dress, in which section, under the able supervision of Mr. Frederick Treves, F.R.C.S., a notable collection of ancient and modern costumes has been displayed, including many examples, intrinsically priceless in value, from the Tower and other public buildings.

One word is necessary respecting the opportunities offered for eating and drinking. Restaurants in profusion are scattered throughout the Exhibition; and the tastes of every dietarian, from the vegetarian to the *gourmand*, can be gratified at special tables in different rooms set apart for the purpose; while in point of cost, a dinner may be had at from sixpence to a sovereign. Of these, too, we must delay further mention until we can refer to them after practical experience of their merits.

The Exhibition, taken as a whole, is of the first importance; it is, as we have said, of unprecedented dimensions; it is excellently arranged; and there is fortunately now no question that its success is assured.

THE LORDS ON PRIVATE LUNATIC ASYLUMS.

THE somewhat flimsy discussion of the treatment of

the private insane which served to relieve the weary monotony of the House of Lords a few days ago spent its force ere it had even become matter of history. Apart altogether from the case of "*Weldon v. Winslow*," which has been made the peg on which to hang the veriest rag of a discussion, we are at a loss to comprehend the attitude adopted by Lords Milltown and Coleridge; nor, granting for argument's sake the wisdom and soundness of Baron Huddleston in his remarks on the case referred to, do we consider such a motion as Lord Milltown's justifiable. He moved that in the opinion of the House the state of the lunacy laws is eminently unsatisfactory, and constitutes a serious danger to the liberty of the subject. The opinions of Baron Huddleston and Lord Coleridge cannot be established by any broad or thorough experience of the subject. The experience of a judge in respect of questions of asylum detention can only be expressed in terms of infinitesimal fractions, and we fear the judicial mind cannot always rid itself of personal impressions or creations of fancy. The reflection of Lord Coleridge on the intellectual capacity, the moral worth, and the medical status of asylum proprietors is unjust and uncalled for. The persistent persecution and vituperation which have been hurled at men who as a class—there are black sheep in every fold—will hold their own with other men for ability, humanity, and righteousness, is a significant comment on the morbid sensationalism which is spreading its roots through our higher circles. No one is rabid enough to assert that our lunacy laws or lunacy administration have reached a state of absolute perfection; nor do we think that asylum proprietors are averse to being relieved of positions which at times are stigmatised with reproach by irresponsible theorists, providing the law of compensation is fully and adequately admitted. Much has yet to be done for the insane to lighten their burdens, and if possible roll them off altogether; and we are justified in saying that much of what has already been done in this direction has been done by the proprietors of private asylums. The liberty of the subject is as sacred an article of faith with them as with those who make it their business to decry their practice; and the lunacy laws receive from them as liberal and humane interpretation as their official responsibilities permit of. Amidst the ever-recurring storms raised by the agitators, how much more has ever been proved against private asylums than could be proved under any system? When abuses cease we are at the end of time; but until then let something better than barking be done, and proprietors will, in their own interest, as well as in that of the public, lend a favourable ear to any measure which shall provide greater safeguards consistent with the well-being of the insane.

SIR ERASMUS WILSON has resigned his seat in the Council of the Royal College of Surgeons of England.

THE latest date for the receiving of essays in connection with the Alexander Memorial Fund is December 31st, 1884.

Notes on Current Topics.

Treatment of Fractured Patella.

THE subject of fractured patella and its treatment, came under discussion again at the Clinical Society of London on Friday evening, when Mr. Christopher Heath described a case treated by means of plaster-of-paris bandage. It will be remembered that this gentleman claimed advantages for such a method in fractures of the patella, over those possessed by Sir Joseph Lister's plan of wiring the fragments; the chief being that danger attending opening of the joint was avoided, while, at the same time, as useful a result ensued. Mr. Henry Morris presented a patient before the meeting on Friday, who certainly has a most useful limb, and who has been treated by extension and subsequent application of an ingenious apparatus, by use of which gradually increasing, regulated flexion of the joint is permitted. As far as appearances at present go, this patient has as good a limb as those resulting from operation by wiring; but it is advisable to remember, as was pointed out by Mr. Turner, that neither Mr. Heath's nor Mr. Morris's patient has yet undergone the test of time; whereas Sir Joseph Lister's cases exhibit most satisfactory evidence of permanent union after eighteen months, or more. Mr. Heath seemed a little inclined to resent the suggestion that similar benefits will not accrue to his patients; but, notwithstanding, he very readily assented to a suggestion that he should hold them in view, and report on their condition after the lapse of a time sufficient to prove beyond doubt the efficacy of his plan of treatment.

Specificity in Disease.

SIR JAMES PAGET and Mr. Hutchinson may very justly congratulate themselves on the stimulus their labours have been the means of applying, in the direction of philosophic study of disease on the part of younger students of pathology. Proof of this stimulus has just been given by the production of a really clever and most suggestive paper on "*Specificity and Evolution in Disease*," by Dr. W. J. Collins, F.R.C.S., who essays with all the vigour of youth to demolish the theories of specific disease which have sufficed to satisfy the acutest physicians of this and every age. Dr. Collins applies the doctrine of evolution to the study of disease, but candidly, and necessarily under the circumstances, declares himself, at the outset, to be an archebiologist. This should not, however, be permitted to dissuade from the perusal of his pamphlet, which is well worthy of being read and considered, although it bears, perhaps, a little too impressively, the evidence of generalisations which, when its author has reached to the experience of authorities whose opinions he condemns, he will be less eager to adopt. Dr. Collins, like older observers, has been puzzled by the occasional occurrence of mixed diseases, possessing some of the characters of two or more so-called specific complaints; he has also viewed with suspicion the quasi-explanations of those forms of illness to which names of definite pathological meaning are attached but which have exhibited, perhaps, none of the fundamental symptoms stated in books to characterise them. Whether, however, the necessity their occurrence puts us under of reforming our notions of disease justifies a wholesale demolition of the structure founded on possibly limited views,

may be doubted; but there can be no question that the spirit of inquiry they tend to foster in ardent investigators must eventually lead to unlimited gains in material knowledge. Such an investigator we undoubtedly possess in the person of Dr. Collins, who can think acutely, and reason logically, but who is, at the same time, a little prone to jump over those terrible gaps which everywhere occur to separate the known from the unknown. This essay he has last produced shows this weakness no less than some of his other work; but, notwithstanding that he mainly quarrels with terms in it, it is a not unwelcome contribution to controversial pathology.

Wood v. Bower and Keats.

In the Court of Queen's Bench on Thursday, before the Lord Chief Justice and a special jury, Messrs. Bower and Keats, surgeons, of Peckham Rye, were once more defendants in an action brought by a manufacturing chemist named Wood, whose child died after tracheotomy performed by the defendants. It will be remembered that Messrs. Bower and Keats have already been subjected to trial in connection with this circumstance, when plaintiff sought to accuse them of malpraxis; and that, on their acquittal the whole medical profession, at the instance of the Royal College of Physicians, united to recompense them for the expenses of the trial and to sympathise with them on their unmerited persecution. This second trial was occasioned by a charge of neglect brought against the defendants by the same plaintiff, Wood, in not warning the latter that he incurred risk of diphtheria by sucking the tracheotomy tube inserted in the trachea of his son. It is true that the man was ill for a few days after, but made a speedy and complete recovery. Evidence was given in support of the charge, including that by several medical men, but on its conclusion the jury declined to listen to anything further, and gave a verdict for the defendants, in whose favour the Lord Chief Justice therefore at once gave judgment. We beg most heartily to congratulate Messrs. Bower and Keats on this termination, and to express strong satisfaction with it, which, we feel assured, will be generally shared throughout the profession.

Metropolitan Hospital Sunday Fund.

A LARGELY attended meeting of the contributors of the Metropolitan Hospital Sunday Fund took place at the Mansion House, on Monday last. The President of the fund the Lord Mayor, occupied the chair. The meeting was specially convened to consider a proposal to abrogate Law VII., with the view of securing the participation in the fund, of the Royal Hospital for Incurables. Sir Sidney Waterlow moved, and Mr. Coope, M.P., seconded, the following resolution:—"That having again reconsidered the terms of Law VII., the Council, after 12 years' experience, are satisfied that it is important to the continuance and well-being of the Hospital Sunday Fund, that it should be maintained; and whilst regretting the bearing it may have on such institutions as the Royal Hospital for Incurables, they are satisfied that the abrogation of this law would entail a material and most undesirable alteration of the fundamental principles on which the Hospital Sunday Fund is founded." The Rev. Mr. Bennett proposed an amendment, but after much discussion the resolution was

carried by a very large majority. The Royal Hospital for Incurables has, indeed, no title to be considered a hospital in the common and well-understood acceptation of the word, for its inmates gain admission to its benefits only after a wearisome and expensive canvass for votes, thus entailing much expense on poor sick persons, most of whom fail in their attempt to gain a sufficient number of votes to secure election. Moreover, if this salutary rule were abrogated, a large number of other institutions—as the blind, the dumb, and the lame—could scarcely be refused participation. Thus the original character of the Hospital Sunday Fund would become materially altered, and the proportional allowance to each institution very much reduced. For these reasons the conclusion come to is undoubtedly a right one, and a proper solution of a difficulty which a few discontented people have been in the habit of making an annual stalking-horse.

National Health Legislation in America.

THE introduction into Congress of a Bill to protect the public health, has provoked from our contemporary, the *New York Medical Record*, a leading article condemnatory of the proposed changes contemplated in the Bill. This makes provision for abolishing the existing National Board of Health, and to substitute, first, "The United States Board of Health," to consist of the Surgeon-General of the United States Army, the Surgeon-General of the Navy, and the supervising Surgeon-General of the Marine Hospital Service. To this Board of three members, the health affairs of the United States will be committed, in place of the National Board of Health consisting of eleven members, most of whom the *Record* places among the foremost sanitary authorities in America. The projected measure is one calculated, our contemporary thinks, to imperil the health organisation of the whole country, and in its centralising spirit it observes to animate the suggestions the Bill contains, the *Record* is forced to see innumerable dangers to the community. Here in London something of the same spirit is being shown in connection with the municipal government scheme, but it would be rash to affirm that the changes to be made are unlikely to be beneficial to public health. Provided that a central Board includes the highest authority that can be obtained, it surely matters but little whether three or three hundred members sit upon it. In either case the State receives the best possible advice for its direction, and when this is fully appreciated the people themselves are not slow to insist on a due fulfilment of the steps necessary to their protection.

Looking Ahead.

IN opening the Summer Session of the class of jurisprudence at Edinburgh University, Dr. MacLagan, Professor of Clinical Medicine, utilised the occasion to deliver an interesting and instructive address, dealing with the consequences of the late celebrations. In the course of his remarks he referred to the many commanding architectural monuments of which the citizens and graduates of Edinburgh have reason to be proud; and then, with one of those bold sweeps of the imagination, almost confined to the Scotch mind, he drew a picture of the quarcentenary

jubilator rejoicing over the completed example of classical Italian architecture with which Dr. Rowland Anderson's name will henceforth be associated. Dr. MacLagan was also impressive in his remarks to his hearers concerning the unique privilege recently enjoyed by them, in being brought into the presence of men whose names are destined to live for ever in the annals of science and learning; and in thus pointing a moral of the late celebration, he was, we consider, acting in a spirit well calculated to enforce the lessons it ought to teach.

Medical Sickness, Annuity, and Life Assurance Society.

It was reported at the last meeting of the Medical Sickness, Annuity, and Life Assurance Society, that the fund had already reached a position at which the number of members entered ensured the solidity of the society; and that there was an adequate margin, according to actual allowance for the working expenses, which had hitherto been kept down to an unusually low point and this would continue to be so. Arrangements were at the same time made for bringing the objects of the society under the notice of the presidents and secretaries of the branches, with a request that they would submit them to the notice of members at forthcoming branch meetings, and communications were received from Mr. Brierley (Manchester), and Mr. Ravenhill (Birmingham), announcing the intention of taking early steps as requested, to form local committees in those two great towns from existing members and others. It was resolved also that all members joining before the end of May should rank as foundation members, and be entitled to the accruing advantage in respect to the date at which they would be free to receive the benefits of assurance. The whole of the preliminary expenses up to date were provided for and written off, leaving the management fund untouched.

Experimental Researches on Hydrophobia.

M. P. GIBIER stated at a recent meeting of the Academy of Science, that in spite of a few cases on record, it is a generally admitted fact that birds can never be attacked with hydrophobia, and even when inoculated with the virus it is very rarely that they show any abnormal symptoms. However, among those fowls on which M. Gibier tried the experiment, there was one hen which became paralysed in the legs and the muscles of the neck. When placed standing on the ground it sank down and could only shuffle along by the aid of its wings. Its head drooped slowly forward until the beak touched the earth, and when quickly raised by the animal it always fell downwards again. Each day the experimenter expected to see it dead but to his astonishment it recovered. This made him think that perhaps the microbe of rabies did develop in fowls, but that owing to the well-known relative insensibility of the cerebro-spinal system or to some other cause yet undiscovered, the results were not necessarily fatal. We afterwards inoculated by the help of Pravaz's syringe a cock and a pigeon with a drop of freshly boiled distilled water holding in suspension infected cerebral matter. The pathological symptoms were very small, especially in the cock, in fact they were unappreciable

except to a practised eye. Both the animals recovered at the end of twelve days. M. Gibier then made an incision in the cranium of the pigeon and extracted a fragment of the cerebral lobe about the size of a lentil. By a microscopic examination of this portion he discovered a micrococcus which he has described in a former communication. He inoculated three rats with the portion extracted, and they exhibited such well developed symptoms that he now considers them subjects specially adapted for the study of this disease. They all three died of hydrophobia, one (the youngest) at the end of ten days, the other two on the 11th inst. At the end of twenty days he inoculated three more and a guinea pig with the cerebral matter taken from the cock. The microscope showed the same microbe as that of the pigeon, but more abundant and in groups of ten to fifteen granulations. The rats all died, and so did the guinea pig on the fifteenth day, all exhibiting similar symptoms. In the birds on which M. Gibier tried this experiment the health was, with the one exception, unaltered, and he was able to determine the moment when the virus left their brain, for in the pigeon already spoken of, it was found impossible to communicate the disease after twenty-eight days from the inoculation. Here now, the impossibility of fowls being attacked with hydrophobia has been proved, and also that they are the only animals which have ever been known to recover from this disease. M. Gibier hopes to make further researches on this subject.

The Forthcoming Sanitary Congress.

At a meeting of the local executive committee, last week, the date was fixed for the opening of the exhibition in Dublin—viz., September 30th. The Agricultural Buildings of the Royal Dublin Society at Ball's Bridge were decided on as the most suitable premises for the exhibition.

A report was received from the Finance Subcommittee stating that of the £1,000 required to defray the expenses of the exhibition and congress the sum of £600 had been already subscribed. The invitation to the Sanitary Institute to hold their congress and exhibition in Dublin had been signed by 400 influential citizens, and as all these signatories would no doubt contribute to the necessary fund for the suitable reception of the congress and exhibition, and as every citizen was personally interested in the advance and spread of practical sanitary knowledge, the committee felt confident of having abundant and prompt responses to their claims for the reception fund.

The following gentlemen have accepted the presidency of the sections:—Section 1. Sanitary Science and Preventive Medicine—Thomas Wrigley Grimshaw, M.D., Registrar-General of Ireland. Section 2. Engineering and Architecture—Charles P. Cotton, M. Inst. C.E., Engineering inspector, Local Government Board, Ireland. Section 3. Chemistry, Meteorology, and Geology—Charles A. Cameron, Medical Officer of Health, Dublin.

It was resolved—"That the honorary secretary and vice-presidents of the three sections of the Congress be requested to take immediate steps to solicit and obtain

proposals for papers on suitable subjects to be read at the Congress sections in accordance with the rules of the Sanitary Institute."

The Annual General Meeting of the Irish Medical Association

Will take place at the Irish College of Surgeons on Monday, the 2nd of June. As the meeting happens to fall on Whit-Monday, and as there is much matter of interest for discussion and disposal, it is expected that the meeting will be largely attended.

Death of Dr. Fairlie Clarke.

WE have to announce with sincere regret the death of Dr. W. Fairlie Clarke, which occurred at Bonchurch, Isle of Wight, on Thursday last, whither he had gone on account of ill-health. Deceased, who had just attained to the age of fifty, was for many years on the staff of Charing Cross Hospital, and a few years ago was by virtue of his abilities as a surgeon and as a writer on surgical subjects, looked upon as a coming man. Unfortunately, his health, which was never robust, gave way, and he had to relinquish his appointments in London and commence life afresh as a country practitioner. He settled at Southborough, near Tunbridge Wells, and at once occupied a foremost position there; but death soon cut short a life of great promise, and the profession thereby has sustained a real loss. With students the name of Fairlie Clarke was a household word, his "Manual of the Practice of Surgery" being an especial favourite, whilst his writings on Diseases of the Tongue, Opacities of the Cornea, &c., are well known to the profession. Deceased was an M.D. Oxon., an F.R.C.S.Eng., and a Fellow of several of the learned societies.

The Elections at the Irish College of Surgeons.

At the election of Examiners on Tuesday, the 6th, to which we referred last week, all the members of the Courts of Examiners were re-elected, except that Dr. E. J. Quinan was placed on the Midwifery Court in place of Dr. W. J. Smyly, who had retired. For the election of Council, which takes place on the first Monday in June, Dr. Storey, of St. Mark's Hospital, and Dr. C. H. Robinson (whom we inadvertently named as a candidate for Examinership), have announced their candidature, in addition to the numerous claimants whose names we recorded in our issue of May 7.

Destruction by Fire of Peterborough Hospital.

ONE of those possible, but fortunately rare, accidents to which hospitals are at all times liable, befell the General Hospital at Peterborough on Thursday last, when the building was almost totally destroyed by fire. At the time of the outbreak there were, in addition to six patients and the regular nursing staff, present in the house several of the medical staff and visitors. It reflects the highest credit on the fire brigade men and those who lent their most willing assistance, that all present in the hospital were got safely to an adjacent house, placed at the service of the authorities for the time. So sudden

was the conflagration, moreover, that a patient was actually being anaesthetised, prior to undergoing operation, when the fire was discovered, and was then removed along with the other inmates, whose condition rendered self-preservation impossible. Within half-an-hour from the outbreak the whole building was in flames, but by strenuous exertions the greater part of the surgical appliances, the medical library, and a considerable quantity of bedding and furniture were saved from destruction. The bulk of the property was thrown out of the windows, but unfortunately two men engaged in this work were very seriously injured, one being crushed by falling timbers. The Dean and Chapter placed at the disposal of the medical officers a large empty house, and this will be used *pro tem*. The hospital was insured for only £3,000. It was presented to the city by the Fitzwilliam family, and has since been considerably enlarged by munificent benefactions.

The Irish Poor-law Inspectorship—Death of Dr. Roughan.

BY the death of Dr. Roughan, of Galway, the Irish Local Government Board has lost, last week, one of its most efficient medical inspectors. While we express the deep regret which all those associated with Dr. Roughan feel, we take the occasion to express the hope that the usual politico-religious job will not be perpetrated in connection with the appointment of his successor. The only person who can have a claim on the ground of special merit and qualification to the office of Medical Poor-law Inspector is one of those who, by following the plough as a medical officer in the Irish Poor-law Service, has acquired an intimate personal knowledge of the working of the system. Other candidates for office may have all the intelligence, activity, and industry necessary, but we repeat that no one is fit for the duties but a Poor-law medical officer, and we trust that no one else will be appointed. It is a gross injustice to the service that those who have by long years of official service shown themselves judicious, industrious, and competent should be passed over for the benefit of some competitor whose chief claim may be that a relative did some influential person an election service; and it seems to us that, before anything is known of candidates, a claim for the preference should be publicly made on behalf of the Poor-law Medical Officers of Ireland.

The Use of Membrane of Egg for Skin Grafting.

IN a case of extensive burn unhealed after six years, Dr. Wilson, of Louisville, has made use of three different kinds of skin grafts, namely, from the skin of a young rabbit, from the human skin, and from the inner membrane of a perfectly fresh hen's egg. Of the three he much preferred the egg membrane as being much more readily obtained, and one egg will supply any number of grafts needed.

The Diseased Meat Trade in Dublin.

As a commentary on the trade in pleuro-pneumonic meat carried on by the Dublin boards of guardians, we may note that within the past month the sanitary

officers of the Corporation seized six and a-half tons of diseased meat, most of which, we fully believe, was put upon the market by the sanitary guardians, for almost the whole of it consisted of beef. Only nine hundred-weight of the whole quantity was voluntarily tendered for examination, all the rest being for sale as sound meat; and when it is recollected that the amount detected probably forms a minute fraction of the whole quantity exposed for sale, it is easy to see where the pleuro-pneumonic beef sold by the Dublin guardians goes to.

The Queen's College, Cork.

LAST week, in reply to a further series of questions by Mr. O'Brien, Mr. Trevelyan stated that the professor of anatomy at Queen's College, Cork, had made no rule that two students should be simultaneously engaged in dissecting each part of a subject. That was only done under extreme necessity. All the fees went to the support of the school, and not to the professor. This statement by the Chief Secretary fully confirms the facts stated by us when we recently wrote on the subject.

Scotland.

[FROM OUR NORTHERN CORRESPONDENTS.]

THE SCOTTISH CONJOINT SCHEME.—Following these remarks we publish an abstract of the conjoint scheme put forward by the corporations. It will be noticed that the examinations are to be three in number, and at periods not far distant from each other, thus keeping the student tolerably close to his work. There are two objections which we have to make. The first is the placing of elementary anatomy in the first and anatomy in the second examinations without defining the extent of the elementary anatomy required. We have seen two octavo volumes of nearly one thousand pages devoted to the elements of anatomy, and we have heard that there is a university in Scotland where the interests of students are watched over with parental solicitude, and where it is suggested that the fact of elementary anatomy occurring in the first examination has necessitated a second course of anatomy with an additional fee to the teacher. Of course, as far as the corporations are concerned such a suggestion is impossible, but we hope for the sake of the student that elementary anatomy will be more clearly defined. The second objection we have to make is the absence of any rule by which the candidate may be prevented from passing the examinations at shorter periods than those defined, thus the second and third within a week or so of each other. To allow a candidate to pass a number of examinations at the end of his curriculum we submit is a mistake, for in keeping up the primary subjects the final and more practical must be neglected.

THE SCOTCH CONJOINT SCHEME.—The following is an abstract of the scheme of conjoint examination to be conducted by the Royal College of Physicians of Edinburgh, the Royal College of Surgeons of Edinburgh, and the Faculty of Physicians and Surgeons of Glasgow:—The examinations shall be held in Edinburgh and in Glasgow, it being arranged that at every third period they shall be held in Glasgow, and at the other periods in Edinburgh. That there shall be three professional examinations, named herein the first, the second,

and the third examinations. To the first examination candidates shall be admissible at the end of the first year (embracing a summer and winter session) of study, on producing certificates of attendance on the prescribed courses of subjects embraced in the examination. To the second examination candidates shall be admissible at the end of the second year of study, on producing certificates of attendance on the prescribed courses of subjects embraced in the examination. To the third examination candidates shall be admissible at the end of the full period of study, on producing certificates of having completed the entire curriculum. That the subjects of the first examination shall be chemistry, practical chemistry, elementary anatomy and histology. That the subjects of the second examination shall be anatomy, physiology, materia medica and pharmacy. That the subjects of the third examination shall be principles and practice of medicine, including therapeutics, medical anatomy, and pathology; clinical medicine; principles and practice of surgery, including surgical anatomy, operative surgery, and pathology; clinical surgery, midwifery and diseases of women; medical jurisprudence and hygiene. That a candidate on passing the third examination shall be admitted and receive the diplomas as Licentiate of the Royal College of Physicians of Edinburgh; Licentiate of the Royal College of Surgeons of Edinburgh; Licentiate of the Faculty of Physicians and Surgeons of Glasgow. That the total fees payable by candidates in respect of the examinations and qualifications shall be twenty-five guineas. Of this there shall be paid, at the first examination, five guineas; at the second, five guineas; at the third, fifteen guineas. For each examination after rejection, at the first examination, three guineas; at the second, three guineas; at the third, five guineas. This document is signed in the name and by the authority of the Colleges named, by the several Presidents.

GLASGOW DEATH-RATE.—For the week ending with Saturday, the 3rd inst., the deaths in Glasgow were at the rate of 27 per 1,000, as compared with 29 in the previous week, and 31, 26, and 25 in the corresponding periods of 1883, 1882, and 1881 respectively.

HEALTH OF EDINBURGH.—The mortality in Edinburgh for the week ending with Saturday, the 3rd inst., was 89, and the death-rate 19 per 1,000. Diseases of the chest accounted for at least 50 deaths, and zymotic causes for 11, of which 1 was due to fever and 3 to measles, the intimations of these diseases for the week being 6 and 52.

SMALL-POX IN GLASGOW.—Dr. Russell, the medical officer of health, reports that there have been 12 fresh cases of small-pox registered, as compared with 21 in the preceding fortnight. Seven belong to the Eastern District, 3 to the Northern, and 2 to the Southern. Of these 9 were removed to hospital, and the remaining 3 were treated at home.

UNIVERSITY OF EDINBURGH.—The following scholarships, bursaries, &c., have been awarded, after examination, at the close of the winter session:—*Faculty of Medicine*: The Vans Dunlop Scholarship in anatomy, institutes of medicine materia medica, and pathology, to R. F. C. Leith, B.Sc.—*proxime accesserunt* being Frederick T. King and J. C. Lamont; the Vans Dunlop Scholarship in subjects of preliminary medical examination, to William Smith—*proxime accesserunt*, Robert Buist and William Fraser, M.A.; the Thomson Bursary, in the same subjects, to John Wilson, a preferential candidate; the Senior and Junior Mackenzie Bursaries in the senior and junior classes of practical anatomy—the senior to James M. Campbell and John Garvie, and the junior to A. C. Cox; and the Senior and

Junior John Aitken Carlyle Bursaries, in the subjects of anatomy and institutes of medicine, and anatomy and chemistry respectively, to W. Fraser Wright and James R. Bibby.

VITAL STATISTICS.—At the eleventh ordinary meeting of the Royal Society, an interesting paper on "Scottish Vital Statistics" was read by Mr. George Seton, secretary in the General Registry Office of Births, Deaths, and Marriages, Scotland. Mr. Seton said it was frequently remarked that the science of statistics in its various branches was, like the law, "gloriously uncertain," and accordingly it was alleged that, from the same set of figures, two intelligent men could draw very different conclusions. Interested motives, preconceived opinions, and illogical conceptions, constituted some of the principal causes of perverted conclusions; and both facts and figures were very liable to misrepresentation. Hence the tendency, in many quarters, to distrust the deductions drawn from figures of almost every kind—more especially in the columns of official reports, and the prospectuses of commercial enterprises. The disregard of what may be termed "disturbing influences" was probably the most frequent cause of erroneous deductions from the published figures. Thus in one town district, with a population of 20,000 persons the mortality of the year was found to amount to 35 per 1,000; while in another, with the same population, the mortality was only 20 per 1,000. A casual reader would be apt to jump to the conclusion that the former district was very much more unhealthy than the other, whereas, if he took the trouble to reflect and inquire, he would probably find that in the one district there was a large hospital or infirmary drawing cases from every corner of the country, and with an 'abnormally large mortality'; while in the other there was nothing of the kind; or that in the one the condition of the house accommodation, drainage, and water supply was very faulty, and in the other quite the reverse. For many reasons, more or less obvious, the mortality returns present even greater contrasts than those applicable to births and marriages. Speaking generally, the number of deaths was materially influenced by the density of the population, but this circumstance had been so frequently adverted to that it was unnecessary to produce any confirmatory evidence. The normal mortality of a closely-packed population might, however, be sensibly lessened by the judicious introduction of sanitary improvements. Weather, of course, exercised a potent influence on the mortality returns in every corner of the kingdom. In conclusion, Mr. Seton stated other disturbing influences than those indicated in the case of each of the three events, but he thought sufficient had been said to show that considerable modifications ought to be made in many instances when dealing with figures illustrative of Scottish vital statistics.

Correspondence.

WHAT IS A MEDICAL ADVERTISEMENT?

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—It appears to me that it is time the above question should be satisfactorily and honestly answered. Some few years since much commotion was caused by the British Medical Association, through its branches, all over the kingdom, denouncing any form of medical advertisement, even to the notice or review of a medical work in a lay paper. What have we come to within the past few weeks? A recent medical work, or at least a popular medical work written, as the advertisement states, by eminent medical men, is now being issued in sixpenny serials. These sixpenny numbers are written by various special authorities,

and no one can deny that these special authorities are men many of whom hold distinguished positions in the profession. The authors have various titles and occupy posts of distinction, from that of attaché to the Royal Household, down to ordinary membership of the staff of leading metropolitan hospitals. They number Fellows of the Royal Society, Fellows of the Colleges of Physicians and Surgeons. In short they are, as the posters state, most eminent medical authorities. Well, lately, in the railway stations, on the walls of dismantled buildings, on the boardings of those now erecting, side by side with the playbills of theatres, placards of soaps, nigger entertainments, or those other attractive wall decorations, which enliven the time of loiterers, has appeared, not only the announcement of the work, but, in some places, also the list of the most distinguished medical authors of these serial numbers of this famous "Book of Health," and of some their professional titles. Within the past few years a highly popular medical directory—I beg its pardon, I should have said "dictionary"—has been, if I mistake not, "noticed" in several popular periodicals, and is sold at many fashionable booksellers, for the benefit of the public. In it, the bewildered "innocent" in search of a physician can readily arrive at a conclusion who he should consult from the numerous quotations from the writings of living authors, arranged etymologically for his convenience, which are contained therein. It is a valuable addition to the library of "Sir Georgius Mida." Certainly, some authorities are taken good care of. Now, Sir, I am not one of those who are squeamish or thin-skinned in the matter of medical advertisement. Let us understand, however, what we mean by advertisement. Let me give some examples of what I consider we may fairly understand to be such:—

- a. Letters to the daily papers on medical topics, which might find more legitimate discussion in the medical journals;
 - b. The circulation, under different forms, of pamphlet literature, whether under the cloak of philanthropic zeal for the public welfare in some hygienic discovery, redressed up sanitary hash, or the indirect circulation of the "eminent authority's" name appended to a pamphlet on anything from a health resort to a water closet; this includes certain contributions to periodical literature;
 - c. The exposure for sale in shop windows or on chemists' counter of eminent specialists' work on medical subjects connected with their specialty, and of their appliances in instrument makers' shops to which the public have access;
 - d. Printing the names and addresses of the staff, and the individual surgeon's name, on hospital papers, or painting them up on boards outside hospitals;
 - e. The delivery of public lectures on medical and semi-medical subjects, and the announcement of the distinguished lecturer's name for days beforehand in the public press and by posters, and carefully compiled summaries of the "able lecture" in the daily papers the morning after its delivery to "a crowded audience";
 - f. Advertisements in the daily papers of the books of medical men and the insertion of reviews of same;
 - g. Placarding or permitting to be placarded on buildings, and in the public thoroughfares, the name and qualifications of any medical man;
 - h. The announcement on a surgery window of attendance and medicine, on the part of Dr. So-and-so, at so much per head per week;
 - i. Wrapper circulars of genuine, patent, or quack medicine, recommended by some eminent physician;
 - j. The writing of a semi-medical, semi-popular work, which, it is well-known, will find its way into the hands of the public, and increase the fame and reputation of the writer;
 - k. Certain advertisements in the *Lancet*, a periodical widely read in most clubs and public libraries throughout the United Kingdom, and sold at many railway bookstalls;
 - l. The establishment of hospitals and societies for the cure of anything or everything under the sun, from corns to inebriety;
 - m. The daily bulletin of the pulse, temperature, appetite, hours of sleep, number of sneezes, of some distinguished patient.
- Now, Sir, please note, that I am not objecting to any of these means of advertising. I do not wish to criticise anyone who takes this method of placing his name before the public; and I should refuse myself to be bound by any

"unwritten law," through which "a coach and four" is every day commonly driven by those who most profess to observe it. What I want to know is, are all these forms of circulating a man's name from the Thames to the Pyramids to be regarded as "advertisements?" If they are, then I say at once, let us all be honest with each other! Let not sentimental hypocrisy, protected by a west-end door-plate, be permitted to shield the aristocratic consultant, as long as that same consultant can resort to any of the less objectionable of the above means of advertisement that can safely be indulged in without attracting attention. Let us "call a spade a spade." In short, let us be even a little honest. If the "struggle for existence" in the medical profession compels the resort to advertisement, in some shape or form, let it be honestly acknowledged that it does so. Then let us not be ashamed to confess the need. Is it not time that the chrysalis of professional sham should be smashed and the moth-grub of pharisaical pretence exposed? At present nought, save the "hollow ghost" of a difference exists between the advertisement which is considered legitimate and that which is unprofessional. It is time that we open our eyes to facts, hear no more of "advertisements," when, side by side with the names of an artistic troupe of itinerant minstrels, we can read those of some of the most "eminent" of the professional men in London, as sponsored by the *Lancet*, and hope to purchase their ideas, on various special subjects, for the sum of sixpence, at any railway stall.

I am, yours, &c.,

ANTI-HUMBUG.

DENTAL EDUCATION AND DIPLOMAS.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—While thanking you for your kind notice of the Dental Hospital of Ireland in your last issue, I feel bound to express my dissent from the last paragraph of your commendatory article. For some time past the dental press in England has, from time to time, thought fit to cast reflections on the Irish College for the action taken by that licensing body in the matter of granting *sine curricula* examinations in dentistry. It is not to be supposed that an august corporation, deservedly possessing a prestige second to none in the United Kingdom, should condescend to answer all the slanders that have been thus either thoughtlessly or maliciously fulminated against it. Far more suitable to its dignity is the course that the College has hitherto adopted—to remain with its serenity undisturbed by these little hostile criticisms, strong in the conviction that it is judicious and in the main right—embodying as it does a liberal and enlightened policy, in helping forward the spirit of the Dentists' Act. Placing within the reach of every reputable non-advertising dentist its *sine curricula* diploma, exacting from each successful candidate a solemn declaration that in the future this diploma shall not be sullied by unprofessional conduct, the Irish College has exerted a strong moral influence to strengthen the wavering, and confirm the good, in a reputable career. Remember that the Irish College creates no dentists at its *sine curricula* examinations. The only creation of dentists that has occurred in recent times has been by Messrs. Tomes and Turner, and their following, from whom arise all the hostile critics above alluded to. From this creation have arisen, I should say, 2,000 new dentists throughout the Kingdom, chemists, druggists, druggists' boys, &c.; each of whom has been given his document of registration, which, neatly framed and glazed in the so-called dentist's office, proclaims to all that the practitioner is legally qualified. I am far from blaming Messrs. Tomes and Turner for this, I regard as unavoidable this great influx of the, to say the least, dubiously qualified at the commencement of the working of the Act. But I think Messrs. Tomes and Turner should have exerted their influence to persuade all the licensing corporations in the United Kingdom to open for a time, at least, their doors to all reputable men in the Dental Register, I think this would have been an enlightened policy. They having by their action enfranchised this motley horde should have done something to enable the better men to obtain a distinguishing mark. They, however, argued otherwise. "The English College," argued they, "held its doors open for four years. The diploma during that time was obtainable on easy terms, the day of grace is

now over, ye cannot enter now." Perhaps the English College, in justice to its curriculum *alumni*, was bound to act thus. Diplomas granted *sine curricula* by any licensing body can never have the same value as the diploma *cum curricula* of the same corporation. The English College may have reflected that their curriculum licentiates had an interest which it was not advisable to disturb, each a vested interest in being able to say, "my diploma dates since 1863, which means that I hold a diploma of greater value than those granted during the years of grace."

But whatever the motives which guided the decision of the English College, the better men had, after the passing of the Dentists' Act, a distinct grievance, in that it left them undistinguishable from the utterly unqualified. It is a matter of history that the English College refused to assist them; and thus the duty devolved on the other corporations to satisfy the legitimate demand for a practical examination from this injured class. Now Mr. Turner, who has had a great deal to say to all this movement, had, at a meeting recently held in Edinburgh, a fling as usual at the Irish College. His strongest point was that the Irish College had granted 316 dental diplomas *sine curricula*, which was a much larger number than had been granted by the English College during its years of grace. He did not tell his audience the exact number of diplomas granted by the English College during the years of grace, nor the percentage of rejections at these examinations; nor did he contrast the difficulty of those examinations with the examinations *sine curricula* of the Irish College; though all these matters were essential to fair contrast. And further, he left utterly unnoticed a vital difference between the conditions in 1859 and those in 1878, which impelled dentists to apply to the Corporations for examination, and which entirely accounts for the much greater number of applications for examination which have been sent in at the later than at the earlier date. Recollect the moving force in 1859 was the private fiat of the English College. In 1878 the moving force was the Act of the Imperial Legislature. The influence of the former extended in this matter little beyond London. The influence of the latter permeated every crvice of the United Kingdom, and extended to the Colonies, therefore the number seeking a *sine curricula* degree now is naturally much greater than was the number twenty years ago.

In truth, the action of the Irish College in the matter of inaugurating the dental diploma has been nearly an exact parallel to that of the English College when that body began dental work. The English College in 1859 opened its doors to all existing reputable dentists. The Irish College in 1878 did the same. For a certain period the examinations were chiefly practical; so it is with the Irish College. After their curriculum was set in order the English College closed its doors to all who had not been in practice before 1859. The action of the Irish College has been more stringent, for long before her curriculum was set in order she closed her doors to all who had not been in practice before 1878. The English College, after the commencement of its curriculum examinations, insisted on all those who were still admissible *sine curricula* being obliged to pass the same examination as candidates *cum curricula*. The Irish College has always let it be understood that this will be her line of action, that once the curriculum examinations commence, all who have still the right to come up without certificates will have to pass the harder examination.

But it may be said the Irish College has been a long time in setting in order its dental curriculum. Naturally, it has been a long time. It must be remembered that the whole dental question came upon the College by surprise. Institutions for the training of dentists had to grow up. The Council of the College acted with prudence and caution. It has always been their policy to grant recognition to those institutions only which submit to, court, and pass the ordeal of official inspection. The Dental Hospital of Ireland has been growing since 1879. Its arrangements have only been perfected since October, 1883. As the requirements for the curriculum of the Irish College embrace two years' attendance on Dental Hospital work, the curriculum examinations cannot come into operation till some time in the year 1885. I confidently repeat that when this time comes the Irish College will turn out a set of dental practitioners possessed of as high a qualification as can be obtained in the kingdom.

One word about our present dental licentiates, those on whom the Irish College has conferred the *sine curricula* diploma. The Irish College has no reason to be ashamed of

these as a class. While a few have turned out black sheep and have had to forfeit the diploma, the vast majority are conducting their practices creditably and respectably, and many not without distinction. Take, for instance, Mr. Verrier, of Weymouth, distinguished all over Great Britain for his continuous gum work; or Mr. Quinby, of Liverpool, who has recently written a charming and most useful dental work. These men are types of a most worthy class, whose sympathy the Irish College has by its liberal action enlisted. As a class, I think these men need not fear comparison with English *sine curriculo* licentiates; and I have no doubt when the curriculum diploma is granted by the Irish College it will be at least on a par with that granted by the English College, both in the certificates of study required for admission to examination and in the tests of knowledge required by the examiners.

Differing, then, as I do from you to some extent in this matter, I fully agree with your wish that when the curriculum examinations commence to be held no distinction may be made after that date in the examination tests applied to the curriculum and the *sine curriculo* students.

I am, yours, &c.,

R. THEODORE STACK.

[We confess to a feeling of great surprise and some regret at finding Dr. Stack, whose earnestness in the cause of dental education has been so well proved, entering the lists as the defender of the continued issue of dental diplomas to persons who make no pretence of having been educated in the speciality; it seems to us that the prospects of raising the qualification of Licentiate in Dental Surgery is much discouraged when gentlemen of Dr. Stack's position, while they beckon with their right hand to the very few aspirants for entry at the narrow gate of the dental profession, hold wide open with their left hand the wide door for the ingress of a multitude of persons uneducated in their business and socially contemptible.

But Dr. Stack's arguments are inconclusive, and his statements in some respects wanting in accuracy, for the true facts as regards the Irish College of Surgeons are these:—When the Dental Act passed in 1878 the College threw its doors open to all registered dentists, not for one "year of grace," but for three. We do not greatly blame the College for having, in this respect, followed the evil example shown it by other institutions, for, though "years of grace" are nothing less than a means of enabling ignorant persons to buy themselves into a position which they have not earned by brains or study, they are generally recognised as a necessarily evil accompaniment of any legal reform of a profession, and as an expedient for filling the coffers of licensing institutions, and the Irish College of Surgeons could hardly be expected to be more virtuous in these respects than its neighbours. It is said by Dr. Stack that it only followed the example of the English College, which granted for four years, and still would grant if asked, its dental licence without proof of education, to certain persons who could pass an examination. Yes, but to whom? The English College threw its doors open in 1859 to those who could prove that they were actually and reputably practising the dental speciality, and the College would not to-day admit *sine curriculo* any candidate who was not *bond fide* in dental practice in 1859, i.e., twenty-five years ago, a complete guarantee, as we think, of the education and respectability of the applicant. The Irish College, on the other hand, offered and offers the same welcome *sine curriculo* to all persons registered as dentists in 1878, and who are they? Let the Minutes of the Medical Council for February, 1881, answer. The Dental Register contains—*a*. Qualified surgeons, a fraction per cent. of the whole number; *b*. Holders of dental diplomas, 15 per cent.; *c*. Unqualified dental practitioners and mechanists, besides chemists and chemists' assistants, barbers, tobaccoconists, and other persons not practising

dentistry, 84 per cent. From this latter class exclusively—a few of them respectable and experienced, though unqualified dentists, the great majority of them tradesmen and their assistants—the Irish College of Surgeons has taken, and continues to take, its dental licentiates. But it will be said that the College admitted none until it had obtained proof of their respectability, and taken guarantees that they would abstain from advertising and other unprofessional practices in the future; and this statement has more or less truth in it; but, as a matter of fact, the testimonials of character were signed by persons of whose reliability the College could possess no information whatever, and indeed, one of the first official acts of the College was to expel from its dental licence an obscene quack and swindler, who had been duly testimonialised, examined, and passed, his certifiers of respectability being, as was afterwards discovered, persons of the same character and pursuits as himself. As regards the undertaking of future good conduct given by each of the dental *alumni* of the College, it is notorious that, in numerous instances, they proved to be waste paper, the recipients of the L.D.S.R.C.S.I. proceeding to advertise and otherwise "push business" as if they had never promised to abstain, and that the College in no single instance save that of the obscene quack above noted has withdrawn the diploma.

We should have been well pleased to have permitted these bygones to be bygones, but that our correspondent and some other leaders of the dental profession have laid upon us the necessity for justifying our complaint against the Irish College, but, having been thus obliged to indict its dental policy, we are called upon to point out that the College shows no shame-facedness in the matter, but, on the contrary, continues and avows its intention to continue the traffic in dental diplomas *sine curriculo* in defiance of the expressed opinion of the dental journals and the British Dental Association, and in violation of its pledge to the Medical Council.

In March, '79, the College laid before the Medical Council a dental curriculum which it deemed sufficient, stating thereupon (see Minutes of G. M. C.) that "after August 1, 1881, no candidate should be admitted to examination who had not pursued" the course set down. In the following July, '79, a committee, of whom the representative of the College was one, was appointed by the Medical Council to bring the dental curricula of the three kingdoms into uniformity, which they did, and thereupon the College repeated its expression of readiness "to accept the regulations laid down by the Medical Council," one of which was that candidates should be admitted *sine curriculo* only up to August, 1881. But when the period to which the College had thus pledged itself arrived, it simply tore up its pledge, and continued the admission of candidates *sine curriculo*, without paying the Medical Council the compliment of informing it that the bargain was broken. More recently still, when a Professor of Dental Surgery had been appointed, and a proper school of dentistry established, a further effort was made to induce the College to purify itself from the taint of this diploma trade, and to keep its pledges to the Medical Council, and it refused to do so, and still continues to furnish the chemists' boys and mechanics who call themselves dentists with the parchment of the L.D.S.R.C.S.I., and all the privileges, honour, and glory thereunto appertaining. As to the examination which the College holds, and which is the only substantial guarantee which it possesses of the quality of its licentiates, all we wish to say is that opinions greatly differ as to its sufficiency

as a test of competency, and our strong belief that, *per se*, it is an utterly inadequate ground for granting any diploma. We have therefore condemned the action of the College in this matter, and we do not think that Dr. Stack's letter furnishes any sufficient justification for it. Nor can we conceive that his defence of the *sine curriculo* diploma is really in earnest, knowing as we do that he, himself, was leader of the effort made in 1878 to induce the College to admit to the L.D.S. no one, howsoever respectable or experienced, save fully-qualified surgeons.—Ed.]

ON THE ANTISEPTIC TREATMENT OF PHTHISIS.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—Dr. Gwynne, though an advocate of the treatment, seems to admit that it is not really antiseptic. As a further illustration of this fact, I will adduce the following circumstance:—In the coal and culm districts of Ireland the lower classes spend a great deal of their time in an atmosphere very strongly charged with sulphurous acid. And yet, according to my experience, phthisis is more rife in these localities than anywhere else. Now sulphurous acid is a very strong antiseptic, and you will find distinguished practitioners adopting it as a treatment, unaware that here it has been ineffectual from generation to generation.

But if the new treatments are not really antiseptic, why not call them simply local? That the local treatment of phthisis has a great future before it I have no doubt, but here, as in surgical pathology, we have a great deal to lose by the use of misleading terms. It is unscientific to class a number of remedies as antiseptic, and call them all useful as such. We ought rather to study the local effects of each drug on its own merits. Carbolic acid, for instance, and its allies, have probably an astringent and devitalising influence on tuberculous tissue. It probably tends to allay the irritation set up by tubercle. Dr. Gwynne finds iodine the least successful. This might very well have been expected from the nature of the disease, it being one in which vascular activity tends to run high, and irritation therefore is contra-indicated.

But in local treatment we are met by a great initial difficulty—the impossibility so far of local insight. When comparative physiology has succeeded in establishing fistulæ into tuberculous cavities, and by endoscopic examination has compared the different local effects of remedies, it will have made a great advance in therapeutics. We may then, perhaps, almost dispense with inhalation, and in some cases actually inject into the lung the required remedy.

I am, &c.,

T. ESMONDE CAHILL.

Literature.

LECTURES ON THE LOCALISATION OF CEREBRAL AND SPINAL DISEASES. (a)

[SECOND NOTICE.]

LECTURES X., XI., and XII. are mainly taken up with the relations and functions of the roots of the optic nerve. Though we have read these chapters closely the conclusions we arrive at are the very contrary of satisfactory. The special relations of the several parts, and the connection they have one with another are to us very obscure. We must add, however, that the author is not by any means dogmatic; but guards himself again and again by cautious expressions. This very caution it is which shakes our own opinions, and, necessarily, our conclusions on the subject. If the author wavers so much, how can the reader accept his teachings? Besides, too, the experiments detailed as being performed on dogs, and of which there are engravings given, can they be accepted as absolute truth? We answer in the negative. At the beginning of our notice of this volume we had to express a similar opinion, and the chap-

ters more immediately before us confirm it. Thus, at page 165, when discussing the way the nervous fibres pass from one side of the pyramidal tract to the other, the author states that three varieties have been observed, and then he goes on to detail these, and says that in so many per cent. the direct is much less important than the crossed fasciculus, in the proportion of 9 to 90; whilst in other cases, again, this proportion is exactly reversed. For ourselves, we were not aware of these differences, which explains, as the author observes, the fact that the paralysis may be on the same side as the lesion, which, however, he says is "less frequent than has latterly been maintained." We have seen one instance of this kind, that is, where the lesion of the brain was on the same side with the paralysis; but there was no minute dissection in this instance to show how the nervous structure was distributed.

The second part of the volume is taken up with "Spinal Localisation, including the Anatomy and Physiology of the Pyramidal Tracts." In the several lectures of which it is composed we find the anatomy of the cord very minutely described, and traced up into the brain itself; and these subjects are illustrated both by comparative anatomy and experiments on the lower animals—just as the author did when speaking of the brain proper. We cannot but observe too, that the author is very familiar with the writings of all the parties who have in any way contributed to throw light on the subject—English, Italians, Germans, and French are all quoted, and get in turn their meed of praise for what they have done. In Lecture XI. we have a highly interesting discussion on the results to the patient, of what the author calls an intra-cephalic hæmorrhage, that is, in other words, if a party be affected with hemiplegia from the cause detailed, how far may he recover the power over the leg and arm? To answer this question the author reminds us of some of the minute anatomy, both as regards the nervous structure and the vascular supply, to which, in an earlier part of the volume, he had directed attention. The lesion, we may observe, is in the central masses, and what is now known as lenticular nucleus is the part specially injured by the hæmorrhage, which is particularly liable to occur in this part of the brain, owing to its special vascular supply and the tendency of these vessels to form military aneurisms. It will be readily understood that if the important parts such as the rotund capsule be only compressed, complete recovery may take place, and the motor power be restored, but, on the other hand, if the internal capsule be injured, and the ventricular cavities penetrated, the case is one of great gravity. Now, can this latter state be diagnosed? Our author says it can, and that the phenomenon known as ankle clonus shows itself when the case is grave, and the paralysis is of cerebral or spinal origin. But if the paralysis be connected with locomotor ataxy, or infantile paralysis the ankle clonus is habitually absent. Some few exceptions, the author states, do occur to these laws, but they are so rare as not to vitiate the general result. So far back as 1863 these points were discovered by Vulpian, the author, and others, and have been acted on ever since; in other words, the French School claim priority for the discovery of these facts.

Into a detail of the ankle clonus, or—as the author calls it in another place—"spasmodic paralysis," we cannot enter here; suffice it to say that fourteen or fifteen days usually elapse from the onset of the attack before the phenomenon of ankle clonus declares itself, and that this state frequently precedes, by several weeks, that rigidity of the limb or limbs which, when it ensues, the author looks upon as irremediable. In our own experience this rigidity does not ensue as soon as is stated by the author, but when once established it was incurable. We have only seen it affect the arm—but very slightly—and the leg; but the latter was not in a healthy state, the patient either dragged it, or in walking, brought the leg round in a half-circle, there being also a rigidity. The patient, too, is liable, in our experience, to suffer severe pains in the arm, which seemed to be purely neuralgic, and any attempt to make the limb straight caused much pain. We have not seen cases where the facial muscles took on contradiction on the paralysed side, but our author states such is not uncommon, and he further mentions that, in very rare cases, a certain amount of improvement may take place in limbs which for years were affected with contraction. He offers no explanation of this phenomenon.

There are many other points of great interest, and prac-

tical moment which still remain. But we find our space forbids, and we think enough has been stated to induce others to read this interesting volume. They will get many suggestive thoughts from its perusal, as it holds out the prospects of arriving at the intricacies, which must still be allowed to surmount that wondrous portion of our frames, the nervous system.

PARRISH ON ALCOHOLIC INEBRIETY. (a)

THE purpose of this treatise, as it is stated in the preface, is far from clear, and the reader is at a loss to comprehend whether it is a highly magnified temperance tract or an attempt at a scientific exposition of a subject which has already been well beaten. The style is unequal, in parts lucid and forcible, in parts circuitous, laboured, and missing its mark. The general plan of treatment is, as the author himself fears, capable of improvement; and the frequent reference to the opinions of other men who are quoted and requested again and again renders the book incongruous in the extreme. In his opening chapter Dr. Parrish asks who are inebriates, and plunges forthwith into a learned discourse on adaptations of foods, drinks, and medicines to the human economy. He loses sight of the main issue raised by his question in a wordy labyrinth of his own creation, and it is virtually left unanswered. Proceeding next to consider the vice and crime aspects respectively of inebriety, he himself wanders between the definitions of vice and disease, and confuses crime with obvious insanity in two of his clinical cases.

The proposition that inebriates proper are not inclined to criminal acts is very fully illustrated by several authentic and apparently reliable quotations. Inebriety is next treated of as a disease, and then follows an interesting chapter on solitary in the inebriates, sequential to which appear differentiations midnight form of "Tendencies to Special Vices," "Traumatic Inebriety," and "Hereditary Inebriates." On the pages devoted to a consideration of the relations of inebriety and insanity appear several excellent and effective passages. With considerable force, and supported by reference to the cases of two young lawyers who died insane, the author urges the wisdom of occasional debauch for brains overwrought and verging on mental disease. Here we have no difficulty in seeing that Dr. Parrish confronts the views of temperance advocates in a spirit of boldness as manly as it is fair and scientific. But in this recognition of insanity he assumes too much for legal acumen where he observes that the law cannot see it unless it does something. "It must hurt or kill, it must steal or burn, or do some overt act before the eyes of the law can even discover its existence." The contention of medical men is that the law frequently fails to discover its existence even then. The question of appropriate institution treatment naturally occupies a place in this book, and it is unnecessary to add that the idea of confining inebriates in asylums for the insane is distinctly discouraged. The conclusions are summed up in a summary which is excellent so far as it goes, but which might have been amplified with advantage. The work is appropriately dedicated to the memory of Dr. Donald Dalrymple.

EPITOME OF SKIN DISEASES. (b)

WE believe that Dr. Tilbury Fox's book on Skin Diseases is as good a work as any published on the subject, but the epitome now before us has little or nothing to recommend it. In the first place, it is hard to understand for what class it is intended, being little better than a note-book, and having very small space devoted to treatment. It can, therefore, be of no use to the practitioner who is already conversant with the subject. The student who wishes to study skin diseases can have very little assistance from a work which at most devotes a page and a-half to the most important diseases. Secondly, we are strongly of opinion that affections of the skin are in themselves so important that anything that would prevent the student of medicine devoting sufficient time to their study ought to be condemned. This epitome, which can only be intended to assist in cramming, cannot be recommended. Small as the work is, there are numerous printer's errors.

THE FIELD OF DISEASE. (a)

ANYTHING coming from the pen of this author commands expectation and respect; and this increases the regret with which we perused, and now criticise, this volume. It is simply a popular account of the multifarious diseases and infirmities which afflict poor humanity, and is alike useless to the educated physician and to the intelligent public. To the former it will convey no information, and the latter will no doubt experience a lively sensation of alarm on perusing it, and will rise with an uneasy apprehension of having half the diseases in the nosological calendar. In this way it will no doubt bring much grief to the professional mill; but we do not see how in any other respect it is calculated to be of service to anybody. Though it describes the leading features of the various maladies, it does not pretend to give any instructions as to treatment; and this is perhaps its most commendable feature. The volume is beautifully printed and brought out.

PHARMACY, MATERIA MEDICA, AND THERAPEUTICS. (b)

THIS is by far the best of the manuals issued by Messrs. Renshaw; it is, moreover, one of the best treatises on the subject that we have ever perused. It may be divided into six parts. The first, about 70 pages, is a good practical treatise on manual compounding; it is profusely illustrated, and would, along with a little practical work, render the student in a short time a manual expert in the branch. Part 2 is the *Materia Medica* from *Acacia* to *Zinziber*. The alphabetical order is adopted, and the subject is well and clearly put forth. In Part 3 the Therapeutics of these medicines are given, and too much praise can hardly be bestowed on this portion of the volume, in which the very latest therapeutical researches are concisely and clearly given. Part 4 is devoted to new remedies of a non-official character, and this is particularly interesting and valuable. Chrysophanic acid, damiana, codeia, convallaria majalis, croton, chloral, eucalyptus globulus, hamamelis virginica, iodoform, eseria, pilocarpine, jequirity, nitro-glycerine, paraldehyde, mullein, rhamnus frangula, salicin, thymol, vaseline, and a host of other new remedies, are succinctly but fully described, with all necessary information as to their uses and modes of application. Part 5 treats of the administration of medicines, with admirable directions as to prescription-writing, in which parsing and syntax are fully gone into in such a way as to make the matter plain to the feeblest Latin scholars. We trust that this portion will be studied; and if it be we predict that that extraordinary abortion "Doctor's Latin" will become a thing of the past. We regret to see that the author adheres to the old-fashioned Arabic symbols, 3, 5, &c., which are dangerous, from their similarity. We wish he would have cast them aside in favour of the more modern oz., dr., scr., & *alia talia*. Part 6 contains tables, weights and measures, and a valuable index of poisons, and what to do in cases of poisoning. The whole book is practically a dictionary; but an admirable index makes any portion of its contents instantly available.

To students the book is invaluable; and we have made it the standard book of our own *materia medica* class. To the practitioner it will be equally useful, for it is not too large for a ready reference book for the carriage or the study table. Anything that is wanted can be found on the moment; and, if the account be brief, it is sufficient for all practical requirements. Busy practitioners cannot read big books; but there is no practitioner who cannot find time to read and master Whittle's little volume. If he do he can safely say that he is up to the advanced standard of pharmaceutical and therapeutic progress. Few branches of the medical art are advancing more rapidly than therapeutics; but our author is well to the front.

St. Mary's Hospital, London.—The festival dinner of this hospital was held at the Freemasons' Tavern on Wednesday last, under the presidency of Lord Carlingford. In their report the Governors stated that during the past year great advancement had been made in the hospital. The liberal

(b) "Pharmacy, Materia Medica, and Therapeutics." By William Whittle, M.D. Second Edition, crown 8vo, pp. 602. London: Henry Renshaw.

bequest of a benefactor had enabled the Governors to erect new buildings; and extensive structural improvements had been made in the old building. The new out-patient department had been opened for the reception of patients, but funds were needed to complete the new wing. The hospital was overcrowded, and many patients had to be refused admission for want of room. During the year the institution had treated 2,322 in-patients, 12,258 out-patients, 10,566 casualties, and 259 married women (attended at their homes), making a total of 25,405 persons relieved. Donations and subscriptions were announced in the room amounting to £2,400.

Royal Medical Benevolent College.—The annual dinner of this charity was held at the Langham Hotel on Wednesday last. Sir Joseph Lister presided, and in proposing the toast of the evening, "Success to the College," said it was now thirty years since it was established. Its objects were twofold—first, to provide pensions and comfortable homes for duly-qualified medical men and their widows in reduced circumstances; and secondly, to provide a sound, liberal, and complete education for the sons of medical men. With respect to the first object, there were no less than fifty pensioners receiving twenty guineas each per annum, and about half of these were provided with comfortable rooms in which to spend the evening of their days. In regard to the second object, the College educated upwards of 200 persons who were resident, besides day scholars, and no less than fifty boys were in the position of receiving their education gratuitously. Some provision had also been made in the direction of educating daughters of medical men in similar circumstances. As yet that had been done only on a small scale, and it was desired to extend this branch of the College. The Chairman made an earnest appeal for support to the institution, which produced in the room subscriptions to about £885.

Death of Drs. Angus Smith and Wurtz.—Yesterday by a sad coincidence two of the greatest scientific chemists of the present century, men of about the same age and representative character, died. We refer to Professor Wurtz, the distinguished French *savant*, whose death in Paris is announced by telegram, and Dr. R. Angus Smith, F.R.S., equally distinguished in this country, whose death occurred at Colwyn, North Wales, after an illness of some months. Both have left imperishable monuments of their great minds, and the announcement of their death will be read with respectful regret.

The Anti-Vaccinators and Small-Pox.—The *Globe* thinks it a great pity that the anti-vaccinationists—who, by the way, seem to be in a state of eclipse just now—have not had their own way. During the last fortnight 346 fresh cases of small-pox were reported, and, but for compulsory vaccination, the outbreak ere this would have assumed the dimensions of a plague. That would have given a prophetic *raison d'être* to the late earthquake, and a deep significance to the fireball at Blackfriars. As it is, those portents are still unjustified by results.

Killed on the Railway.—A melancholy accident occurred last week to Dr. J. Foulkes Jones, of Towyn, Merionethshire, who, whilst walking along the line, was knocked down at Flint by the Irish Mail from London, breaking an arm and leg, and being otherwise seriously injured. He was taken to the Chester Infirmary, where he died after much suffering on Monday last.

Pass Lists.

Royal Colleges of Physicians and Surgeons, Edinburgh.—*Double Qualification.*—The following gentlemen passed their first professional examination during the April sittings of the examiners:—

Robert Archer Nesbitt, William Gregory Davies, William Henry Clark, Benjamin Allen Maturm, William Arthur Powell, Richard Harrison, Samuel Blackwell Fenn, Nathaniel Ingram Edghill, Edward James Sheppard, Richard Kelly, Albert Edward Tunstall, Alexander O'Reilly Blackwood, William John Morton, James Edmund Leach, David Denholm Black, James St. Johnston, Richard Arnold Johnston, Allan Mill, Joseph Sanbuck Scott, Frederick Buckham, Alfred William White, George Thomas Smith Hughes, John Wingfield, Louis Emile de Boucherville, William Henry Carter, James McGaw, Edwin Priestley, William Beale Marston, Robert John Willis, Hervie Theophile Dardier, John Connell, John Thomas Haworth, James Whitelaw Alexander, Morgan John Morgan, Edwin Evanston Jones, John Edgar Tisdall, Anthony Daly Dunn, Alfred Henry Whitwell,

James Thornhill Woodhouse, Henry Powell, Robert John Beecome, James Williamson Patrick, Clarence Beesley, Thomas Godley, Duncan Robert Macdonald, Arthur Fowler Turner, Patrick Austin Moriarty, David Davies, Robert Thomson Paton, Vincent Peter Mart, Devereux Gwynne Hughes, Michael Fitzgerald, Frank Reginald Longden.

The following gentlemen passed their final examination, and were admitted L.R.C.P. Edinburgh and L.R.C.S. Edinburgh in April and May:—

George Todd, Charles Builand, Frank Laird, Frederick William Salter, Lewis Gordon Lawson, John Scott Haldane, Ernest Evan Llewellyn, John Leslie Clarke Cox, Richard James Sallie Wheller, Hugh St. David Griffiths, Sydney Morse, Henry Robert Heather Bigg, Cyril Somerset Earle, Robert Balfour Graham, Herbert William Gibb Doyne, James Joseph Wandlas Pearry, Michael Domville Hart, Alfred Edward Drury, Harold Arthur Tuxford, John Joseph McNulty, Alex. McKelvie, Alex. Ernest George Langschmidt, Edward Campbell Hearne, Hugh Griffith Hughes, Henry Goodwyn, Percy Sprague Oram, George Vincent Fourquemin, Richard Hugh Brew, William Griffith Evans, Philip Edmund Perot, Walter Wignall, Thomas James Randolph Clarkson, Griffith Gryffyd Jones, Francis William Robert Scott, John Francis Thomson, Bouvier Francis Primrose McDonald, John Nickolson Constable, John Kenas Goodall, Colin Campbell McFarlane, Crisbie Bignall Harvey, David Gibson Inksetter, John Thomas Jones, John William Jones, Evan Jones, James Warwick Elliott, Arthur Edward Newbery Browne, George McClean, Henry William Faulkner, William Gregory Davies, William Disbrow, Brydone Jack, Samuel James Camor, Thomas Kean, John Winchester Spear, William Park Lyon, Vincent Octavius Taylor, George William O'Flaherty, David Gilbert Donaldson, Charles Alfred Mitchell.

Royal College of Surgeons, Edinburgh.—The following gentlemen passed their first professional examination during the recent sittings of the examiners:—

Henry Hugh Williams, Arthur Edward Nevins, Walter Smithies, John George Uppleby, Ernest Edmund Taylor, Robert Sinclair Smith.

The following gentlemen passed their final examination and were admitted L.R.C.S.E.

Robert Henry Blakie, Skene Keith, John Thomson, William Kirman Paul, Robert Smallies, Kotapurvala Jansettee Framjee, Samuel Garland Sharpe, Charles Gilroy King, James Charles Francis Whitcher.

The following gentlemen passed their first professional examination for the Licence in Dental Surgery:—

Leonard Latham Wilde and James Leslie Fraser.

The following gentlemen passed their final examination and were admitted L.D.S. Edinburgh:—

James Graham Munro and Alfred Henry Thomas.

Notices to Correspondents.

DR. ROBERT J. LEE.—Your paper on "Antiseptic Inhalation and the best Method of Conducting it" is marked for early insertion.

LARGO.—The first examination for the degree of Bachelor of Medicine takes place on June 6th, biology being first on the list of subjects, followed by chemistry, physics, and practical laboratory work; for this your "Handbook for the Physiological Laboratory," by Harris and Power, will be sufficient. You will need a more modern chemistry than the one you have.

A SECOND YEAR'S MAN.—Write to the Editor of the *Students Journal*; it is a subject that never comes across our path.

ON THE USE OF TANNIN IN NASAL POLYPI.

To the Editor of the MEDICAL PRESS AND CIRCULAR.

SIR,—At page 433, the use of tannin in the treatment of nasal polyp is attributed to Dr. Bell, of Canada. A glance at the "Medical Digest" will show, at Section 506: 4, that Mr. T. Bryant demonstrated the specific value of the drug as snuff in 1867, and its efficacy is such that there is seldom any occasion to inject a solution into the tumour.

Yours, &c.,

RICHARD NEALE, M.D. Lond.

South Hampstead,

May 8, 1884.

MR. A. A. PERCY (Glasgow).—Your patent is another illustration of the axiom that "there is nothing new under the sun." We have seen exactly similar articles in Newcastle-on-Tyne more than a year ago.

MR. MONTAGU WILLIAMS (North-Eastern Hospital for Children) is thanked for his interesting report.

ST. PETER'S.—We do not possess the information at the moment; but it is always possible to obtain it at the cost of very little trouble. If it is desirable to carry out the inquiries now, we shall be glad to put you in communication with a gentleman who can materially assist your undertaking.

DR. MARTIN.—You do not mention the doses you have been accustomed to prescribe. Undoubtedly the remedy is of little use unless given in fair amount at frequent intervals until the desired effect is produced. Five grains every six hours for thirty-six or forty-eight hours is not too much. It may be combined with other lowering measures with advantage.

MR. HANNAY.—You are quite right. The College of Surgeons in England will not in future require that rejected candidates, when applying for re-examination, shall present a signed certificate from the teachers of their school. The pass and pluck list is, likewise, thing of the past.

MR. CUMMING.—You cannot be prevented at the next examination. See reply above.

DR. SANDERSON.—The tumour is most probably cystic and fatty.

SHAM MEDICAL DIPLOMAS.

To the Editor of the MEDICAL PRESS AND CIRCULAR.

SIR,—The annotation headed as above in your issue of 23rd April comes *à propos* as anticipatory of the measure of medical reform promised for the present session, unless the African, Franchise, Shipping, or Cattle questions should overpower the present Parliament. But should a general election make its way, whether opportunely or not, let us hope that fewer lawyers and professional patriots will find a place in the new House than in its present unhappy composition. In the realisation of that hope alone is the chance of the public health or the doctors' questions being considered or satisfactorily amended. For while law, railways, ships, land, mines, and miners count so many representatives in the Commons, neither the doctors nor their patients can be permitted to encroach upon the public time.

Under the present state of the law, any man or woman may practise the profession of medicine for gain, and nobody has a right to object. Hence the announcements of those charlatans which meet us at every street corner, and in the columns of low-class journals.

Assuming for a moment the existence of quack lawyers, how long would their announcements be allowed the light of day by those who are ever so greedy of fees, and who have the privilege of making laws for us which are no sort of protection whatever? What an instant outburst of legal enthusiasm should we witness for the immediate suppression of the unqualified offenders!

When a Medical Bill, formulated by the Duke of Richmond, was introduced into the House of Commons about five years ago, Mr. Serjeant Simon, Q.C., and Mr. Thomas Burt, M.P., were its two chief opponents. The Franchise question seems now to be an immediate probability, and in anticipation thereof Mr. William Crawford, Durham, has been selected by the miners as their candidate to contest North Durham at the next election. That upon the medical question he does not endorse the views of Mr. Burt may be learned from reading the following extract from his address to his constituents in anticipation:—

"UNQUALIFIED MEDICAL MEN."

"You should not only protest, but positively refuse having these unqualified men pitched amongst you, either by owners or other qualified men. It is quackery of the worst kind. A qualified man is put down as the *colliery doctor*, and men are supposed to subscribe to him, but as he cannot possibly attend himself he appoints an assistant, who is sometimes not qualified as a medical man. He has not taken a diploma and is therefore not licensed to practise. Sometimes these qualified men draw from collieries, as clear gain, many pounds in the fortnight more than they pay their unqualified assistants, and yet the qualified man is seldom seen on the spot. Whether your doctor be a principal or an assistant, insist upon it that he must be of your own choice and a qualified medical practitioner."

If Mr. Crawford succeeds in reaching the House of Commons, let us hope that he will succeed in winning over a sufficient number of honourable members as shall ensure for our profession

JUSTICE.

DR. CARRUTHERS.—The reports ought not to be posted later than Friday, as otherwise they are likely to be delayed until too late to be made use of.

R. F. P.—Many thanks; name and address sent as requested.

L. E. G.—Not for a month, at least.

MR. RICHARDSON.—There can be very little doubt the system by which the affairs of the institution you name are regulated is in many respects needful of being reformed. It can only be dealt with satisfactorily, however, and at the same time thoroughly, under circumstances that we are not in a position to command; so that we have long past left the matter to be dealt with by those whom we have been content to direct in the right path for securing the end you have pictured. So far good progress has been made, but even now the whole is not quite ripe for final exposure.

A COUNTRY DOCTOR AND A GENERAL PRACTITIONER IN THE COUNTRY both write on the same subject, that of advertising consultants. As the letters, however, reveal facts which those to whom they refer might consider it libellous to publish, we are compelled to decline the risk of laying them before our readers.

A. R. P.—We cannot answer your question any further than by saying that the Bill has not yet been read a first time in the House of Commons. Its fate is probably a good deal dependent on the progress made with public business.

UNGT. SULPH. CO.

To the Editor of the MEDICAL PRESS AND CIRCULAR.

SIR,—Replying to a correspondent in your last issue that the above is commonly known as "trooper's" ointment, allow me to state that this is not so, but that blue (mercurial) ointment goes by that name, and its use is quite familiar for the cure of "crabs," or body lice, infecting the pubes and armpits, pediculi pubis. Your correspondent would find liq. calc. sulph. a much cleaner and more expeditious dressing for the cure of itch.

Yours, &c.,

N. HANNAH.

Rock House, Ashton-in-Makerfield,
May 12, 1884.

Meetings of the Societies.

WEDNESDAY, MAY 14TH.

EPIDEMIOLOGICAL SOCIETY OF LONDON.—At 7.30 p.m., Council Meeting. At 8 p.m., Dr. Joseph Ewart, The Colonisation of the Sub-Himalayas and Neilgherries, with Remarks on the Management of European Children in India.

ROYAL MICROSCOPICAL SOCIETY.—At 8 p.m., Dr. P. Herbert

Carpenter: The Minute Organisation of the Nervous System of Crinoids.

THURSDAY, MAY 15TH.

HARVEIAN SOCIETY.—At 8.30 p.m., Mr. Edmund Owen, A Case of Hypospadias (sex of the child originally mistaken).—Dr. Cheadle will re-open the discussion on Scarlet Fever.

FRIDAY, MAY 16TH.

ACADEMY OF MEDICINE IN IRELAND (Medical Section).—At 8 p.m., Living Specimen: Dr. H. C. Tweedy, Case of Tinea Favosa. By card: Dr. C. J. Nixon, Cerebral Ramollissement.—Dr. H. C. Tweedy, Microscopic Slides showing Achlorion Schönleini. Business: Discussion on Mr. J. B. Story's paper, On Atrophy of Optic Nerves, and Paralysis of First and Fifth Nerves from probable Brain Tumour. Papers: Dr. C. J. Nixon, Reflex Paralysis.—Dr. K. Franks, Intussusception.—Dr. Walter G. Smith, Lupus, and its Treatment.—Dr. T. More Madden, A Case of Delirium Tremens in a Child eight years of age.—Dr. H. C. Tweedy, Notes on a Case of Tinea Favosa.

ROYAL INSTITUTION.—At 8 p.m., Professor Odling, The Dissolved Oxygen of Water.

SATURDAY, MAY 17TH.

ROYAL INSTITUTION.—At 8 p.m., Professor Bonney Microscopical Geology.

Vacancies.

Armagh Union.—Workhouse Medical Officer. Salary, £120. Election, May 20.

Bucks County Lunatic Asylum.—An Assistant Medical Officer. Salary, £100, with board and furnished apartments. Applications to the Clerk to the Committee of Visitors by May 15.

Coombe Hospital, Dublin.—Assistant Master. Applications to Master, or at Coombe Hospital.

Dunshaughlin Union, Dunbayne Dispensary.—Medical Officer. Salary, £125. Election, May 17.

St. Marylebone General Dispensary, Cavendish Square.—Resident Medical Officer. Salary, £105, with furnished apartments, &c. Applications to the Secretary by May 19.

Sunderland Infirmary.—A Senior House Surgeon. Salary, £100, with board and residence. Applications to the Chairman of the Medical Board by June 2.

Appointments.

BINDLEY, V. N., M.R.C.S., Assistant Surgeon to Her Majesty's Convict Prison, Dartmoor.

BREWSTER, W., M.R.C.S., Resident Medical Officer to the York Dispensary.

CHALMERS, G., M.B., C.M. Ed., Medical Officer for the Newbottle District of the Houghton-le-Spring Union.

MORRISON, J. T. J., B.A., B.S. Cantab., F.R.C.S. Eng., Resident Surgical Officer to the General Hospital, Birmingham.

MUDGE, T., M.R.C.S., Medical Officer for the Western District of the Redruth Union.

NISBET, J. T., M.B., C.M. Ed., Resident Physician to the Royal Hospital for Sick Children, Edinburgh.

SMITH, J. M., M.B., C.M. Aberd., Medical Officer for the First District of the Romford Union.

SPICER, F., M.B., M.R.C.S., a Resident Medical Officer to the Royal Free Hospital, Gray's Inn Road.

STEWART, G. T., M.D., F.R.C.P. Ed., a Consulting Physician to the Royal Hospital for Sick Children, Edinburgh.

TATHAM, C. J. W., M.R.C.S., Assistant Medical Officer to the Warneford Asylum, Oxford.

Births.

DICKSON.—May 7, at South View, Bath Street, Jersey, the wife of John Edward Dickson, M.B., C.M., of a son.

WILSON.—May 5, at Minto House, Leytonstone, Essex, the wife of Albert Wilson, M.D., of a daughter.

Marriages.

SMITH—JONES.—May 8, at St. Cyprian's Church, Liverpool, George Francis Kirby Smith, F.R.C.S., to Amy Ethel, daughter of the late Robert Norris Jones, of Liverpool.

Deaths.

ARNOLD.—May 2, at Closebrooks, Antibes, France, John Arnold, M.D., of Port of Spain.

BAINBRIDGE.—May 6, at his residence, the Heriots, Droitwich, W. H. Bainbridge, F.R.C.S., aged 78.

CARNEGIE.—May 4, at Chesterfield, John Carnegie, M.A., M.D., aged 50.

CLARKE.—May 8, at Bonchurch, I.O.W., William Fairlie Clarke, M.D., F.R.C.S., of Southborough, Tunbridge Wells, aged 50.

EARLE.—May 6, at Guernsey, Edward Septimus Earle, F.R.C.S., L.R.C.P., late of Brentford, Middlesex, aged 50.

GALE.—May 5, Henry Stanley Gale, M.B. Lond., of Hyde Road, Manchester, aged 47.

MAY.—May 8, at Sidmouth House, Reading, George May, F.R.C.S., aged 85.

ROUGHAN.—At Palmyna Terrace, Galway, Dr. George F. Roughan.

WILLIAMS.—April 27, at his residence, Southsea, Henry Francis Williams, M.D., Deputy Surgeon-General H.M. Indian Medical Service (retired).^a

ON THE INCREASE OF INSANITY; WITH SOME SUGGESTIONS FOR THE REFORM OF OUR LUNACY LAWS AND PRACTICE. (a)

By T. MORE MADDEN, M.D., F.R.C.S.E.,

Obstetric Physician Mater Misericordie Hospital, Physician Hospital for Sick Children, formerly Examiner in Obstetric Medicine, Queen's University Ireland, and former Vice-President Dublin Obstetrical Society.

In the "Transactions" of this Academy, I recently discussed certain mental and nervous complaints, and I now desire to call attention to some medico-legal aspects of this subject. At the same time I shall offer further evidence of my former contention that insanity and cerebro-nervous disorders have lately increased to a very serious extent amongst all classes. This is more especially marked amongst women, in whom mental derangements are frequently traceable to reflex irritation from uterovarian causes, and owing to the general non-recognition and neglect of these sources of cerebral disturbance many women are now needlessly and improperly confined in lunatic asylums. Secondly, I wish to point out that the present administration of these institutions, and the laws by which this is controlled, tend to various abuses amongst which that just referred to may be numbered.

Finally, I venture to offer some suggestions for the better administration of such asylums, and for certain amendments which appear urgently called for in the existing lunacy laws.

In the subjoined statistics will be found the clearest evidence that insanity has rapidly increased and is still increasing in these countries, whilst its curative treatment has not advanced in the smallest degree. This non-improvement in the curative treatment of mental diseases, is probably largely due to the fact that all questions relating to insanity and other cerebro-

nervous disorders are too generally abandoned by medical practitioners to those specialists who, being officially connected with lunatic asylums, are therefore conceded an exclusive and vested interest in all that relates to psychological medicine. It appears to me, however, that the questions included under this heading equally concern every medical practitioner, who may be called on to diagnose and treat the incipient stages of mental derangement, and those diseases which, if neglected, may eventuate in madness, and on whom the law still imposes the responsibility of signing the warrant for the confinement of those restrained as lunatics.

The statistical evidence afforded by the official and other reports to which we are about to refer of the increase of insanity and of its greater prevalence amongst women is so conclusive, that it seems difficult to realise how any person of ordinary intelligence, not being a medical superintendent of a lunatic asylum or a commissioner in lunacy, can dispute the fact.

At the present time 1 in every 414 of the population of England and Wales, is a registered lunatic. In the year 1800 there was only 1 lunatic in 7,300 of the population (Dr. Powell). In 1806 a Select Committee of the House of Commons reported that the total number of lunatics in England and Wales was 2,248. In 1819 there were 6,000 (Burrows). In 1823 6,000. In 1826 upwards of 14,000 (Halliday). In 1845 when the Commissioners in Lunacy came into office there was one lunatic in 800 of the population, whilst by the last or thirty-seventh annual report of the same commissioners we find that the number has risen to 76,796 or one in 414, being an increase of 1,923 insane persons since the previous year's report. Of these, 42,482 were female lunatics and 34,482 males. The increase in the number of female lunatics within the year was 1,188 and that in male lunatics only 676. Notwithstanding these statistics, however, the Commissioners of Lunacy in their last report still deny the actual increase of insanity, and endeavour to explain their own figures away, or to minimise their importance as far as possible.

In Scotland also the increase of insanity is shown by the last official reports; whilst in Ireland, which some

(a) Read before the Academy of Medicine in Ireland.

recent writers say is comparatively free from this visitation, the proportion of insane persons is greater than in any other part of the British Empire. Since 1851 the population of Ireland has decreased from 6,574,278 to 5,159,839, and yet within this time there has been an increase of 41 per cent. in the number of registered lunatics. In 1881 this amounted to 9,980 or one in 1,291 of the population, and at present it has risen to 13,820 that is one in 369. But if we add to this the 6,000 lunatics who were shown by the last Census Report, which reflects such great credit on the Registrar-General, Dr. Grimshaw, to be at large throughout the country, then there are no less than 19,820 lunatics in Ireland, that is one to every 214 of the population. Of the lunatics under restraint in public asylums 6,866 were males and 6,955 females, and of those in private asylums 385 were female and 236 male lunatics. The proportion per cent. of stated recoveries in cases of insanity, notwithstanding the boasted progress of psychological medicine, appears to be no greater at present than was the case in the earliest period of which we have any record in the history of lunatic asylums. The oldest of these institutions in England, is Bethlem, and there nearly two hundred years ago, the proportion of recoveries was actually much higher than is now the case in any of our lunatic asylums. Thus, from 1684 to 1703, 1,294 insane patients were admitted into Bethlem, and of these 890 or in the proportion of 2 in 3 were cured (*Tyson cited by Burrows*), coming down to a more recent period in the Stafford asylum, during the ten years from 1818 to 1828, 43 per cent. of the patients admitted were cured. About the same time in the Lancaster Asylum the proportion of recoveries was 39 per cent, and in the Wakefield Asylum 42 per cent. (Pritchard). In 1874, according to the official report for that year, the proportion of stated recoveries to admissions in the public and private lunatic asylums of England and Wales, was 40.53 per cent. This has not been since exceeded, and in the last year reported on, the proportion of recoveries was still smaller.

The foregoing statistics prove that insanity is yearly increasing in prevalence amongst all classes, and that this increase is most notable in women, whilst its curative treatment has made no apparent progress.

I may now add a few words on some of the causes of this growing tendency to mental disorders observable of late years. These causes are moral as well as physical, and both largely arise from the changed conditions of society within the last couple of decades, the race of life being now too generally run at a pace destructive alike of mental and bodily health.

Amongst the many circumstances which thus conduce to the increase of insanity, are the prevailing tendency to alcoholism in all classes, now so apparent to those who, as medical practitioners, are most conversant with the inner life of modern society. Secondly, the growing luxuriousness and sensuality too generally characteristic of the youth of the present day. Thirdly, the forced system of education, by which the mental powers are over-strained and prematurely exhausted in the efforts to acquire that superficial smattering of pseudo-knowledge which is now deemed universally essential. And, fourthly, the misdirected tendencies of modern female education in youth, and the neglect of suitable occupation for women in after life, must be recognised as powerful moral factors in the etiology of insanity.

Having already fully discussed the predisposing and exciting physical causes of reflex cerebro-nervous disorders in women, and especially the influence of peri-uterine irritation in their causation, in the transactions of the Dublin Obstetrical Society and of the Academy of Medicine, as well as in the *American Journal of Obstetrics*, Dr. Quain's "Dictionary of Medicine," and in the *British Medical Journal*. I shall not now again dwell on them, I may, however, add that further experience has proved that more than thirty per cent. of all patients under observation in the gynaecological department of one of the hospitals with

which I am connected, show some symptoms of nervous, hysterical, or mental disturbance consequent on their gynaecological complaints.

The functional connection between the cerebro-nervous and reproductive systems in women, is evinced at every catamenial period, from the first appearance of menstruation to its cessation at the menopause; as well as every deviation from normal menstrual action, by the general manifestation at these times of hysterical or nervous symptoms. In chronic ovarian uterine complaints and in all forms of displacement of the uterus, the reflex consequences of peri-uterine irritation are demonstrated by various cerebro-nervous derangements ranging from hysteria to epilepsy and insanity.

A peculiar tendency to nervous or mental excitability generally accompanies pregnancy. And the reflex peri-uterine causation of certain cerebro-nervous disturbances is still more marked during parturition in puerperal convulsions, and after delivery in puerperal mania.

The period of the change of life or menopause is one of special interest in this connection, and in many instances I have seen women from this cause exhibit such excitability of mind and temper, perversion of the moral faculties and disturbances of the mental powers, that it was most difficult to say whether or not that undefinable boundary line, which separates sanity from lunacy, was passed or not. Under these circumstances I have more than once been instrumental in delivering women thus affected, from needless restraint in lunatic asylums, and by appropriate treatment, assisted in their complete restoration to mental as well as physical health.

The number of such cases that have come within my own cognisance, and the growing tendency to place all patients suffering from any mental derangement, however trivial and transitory, in lunatic asylums, where little, if any, attention is given to the treatment of the morbid conditions just referred to, justifies the conclusion that, amongst the fifty thousand female patients now in our lunatic asylums, there are many who should never have been admitted, and others who might be cured of the cerebral consequences of peri-uterine irritation by medical care, and who in the absence of such treatment, are now improperly detained in these institutions.

I therefore venture to suggest some much needed reforms in the laws and system of lunacy administration, under which these and other abuses are thus possible.

The facility with which any person can be legally consigned to a lunatic asylum is entirely indefensible. There now are upwards of twenty-four thousand medical practitioners on the British Medical Register, and any two of these, however inexperienced they may be, can, by their certificate (the other required legal formalities being of entirely secondary importance), imprison any man or woman in these realms in a lunatic asylum. That this power is well used as a rule is unquestionable. But that it is liable to abused must also be obvious. Not long since I was asked to give a lunacy certificate in the case of a lady who had been a patient of mine, and in whom I could discover no evidence of insanity. Another physician also refused to pronounce the patient mad. And yet within a few days, on the same document signed by others, she was sent as a lunatic to a private asylum. Those who gave this certificate may probably have been right, those who refused may of course have been wrong. Still a case like this, which I am sorry to say, has not been singular in my experience, serves to show that a question of such importance should not be left to the arbitrary and irresponsible judgment of any two gentlemen who happen to be on the Medical Register.

It would be easy to remedy this by enacting that no person should be confined as a lunatic save on the certificate of two official and responsible medical Visitors or Inspectors in lunacy. Moreover, in the case of supposed female lunatics one of these officials should be a physician, who has had some actual clinical experience of the various special functional disorders of women, the reflex

consequences of which may eventuate in insanity or simulate it.

The law relating to the care and custody of the insane and the official administration by which this is supervised, differs widely in the several divisions of the United Kingdom. In England the authorities charged with the duty are the Commissioners in Lunacy under the Act of 1844. In Ireland almost similar functions are discharged by the Inspector-General of Lunatics, nominated in 1845. And in Scotland still larger powers in this respect, are exercised by the Board of Commissioners in Lunacy, established in 1858.

(To be continued.)

THE HISTORY OF ANÆSTHETICS.

By W. ROGER WILLIAMS, F.R.C.S.,
Surgical Registrar to the Middlesex Hospital.

THE numerous experiments made to prevent pain in surgical operations bear so delightful a testimony to the humanity and self-sacrifice of their authors, that the recapitulation of them cannot be other than an agreeable task. Instructive, too, because the history of their successes and failures may lead others to new discoveries. Labour in this field has been fruitful beyond all expectation, but still much remains to be done. Indeed, it is now generally admitted that the essentials of anæsthesia are not satisfactorily attained by any of the agents in ordinary use. Hence the need for further inquiries. Unfortunately, modern investigators are hampered by recent unjust legislative enactments forbidding experiments on animals, and sadly discouraged thereby. Among the thirty or more substances proved to possess anæsthetic properties, no doubt, if we knew more of their nature and how to employ them to the best advantage, there might be found at least one more suitable in every respect than any of those now in use. Nevertheless, though not absolutely perfect, the modern practice of allaying pain in surgical operations by the inhalation of various narcotic vapours may be described, without the least exaggeration, as one of the greatest and most beneficent discoveries of modern times.

It is now such a matter of routine, that we are apt to forget it originated only some forty years ago. The merit of making this great discovery undoubtedly belongs to America.

The prosecution of individual claims gave rise to many heated and acrimonious discussions. Time has softened these. The rival claimants are dead now. We can review the question in a calmer spirit.

Long before the introduction of any of the anæsthetics now in use a variety of measures had been suggested and employed for producing insensibility to pain. The fumes and extracts of mandragora, (a) Indian hemp, (b) and other soporific drugs, (c) had been so employed by the mediæval, ancient Roman, Greek, and Chinese surgeons.

With regard to the mandrake (*Atropa mandragora*), the accuracy of the ancient statements concerning its narcotic properties has been proved experimentally in our time by Dr. B. W. Richardson.

In the 16th and 17th centuries, Valverdi and others caused stupor by pressing on the carotid arteries after the manner familiarised by modern grotters. Compression of the nerves, suggested long previously by the celebrated Ambrose Paré, was tried in 1784 by Moore (d). Mesmerism and hypnotism have also been essayed.

By far the most important epoch in the history of modern chemical science is the century 1720-1820. This period embraces the discoveries of Hales, Black, Cavendish, Priestley, and Davy—the fathers of English chemistry—and of Bergman, Scheele, Lavoisier, and Berthollet abroad. Previously, very little was known of the nature and properties of the various gases and æriiform substances. Now, a flood of light was thrown on this difficult subject.

The most successful in these researches was Priestley, than whom no single person ever discovered so many new and curious substances. Among other things, he discovered *nitrous oxide gas* in 1772. This he did by exposing the so-called *nitrous air* (nitrogen dioxide)—then recently discovered by Hales—to the action of moist iron filings, liver of sulphur, and other easily oxidisable substances, thus depriving it of a portion of its oxygen and reducing it to the condition of nitrous oxide (nitrogen monoxide) or *dephlogisticated nitrous air* as he called it (a). By a great variety of most ingenious experiments, he succeeded in demonstrating the chief properties of this remarkable substance, and in all probability he would have discovered the toxic and anæsthetic properties also, had he employed larger animals instead of mice, which died when immersed in it. For further particulars of these and many other interesting experiments the curious reader is referred to Dr. Priestley's celebrated work entitled "Experiments and Observations on Different Kinds of Air."

The great interest excited by these discoveries reacted powerfully on the medical world. Pneumatic chemistry called into existence a new branch of therapeutics—pneumatic medicine, as it was named by its founders, who hoped to cure diseases, and especially consumption, by the inhalation of various gases and vapours. A "Medical Pneumatic Institution" was set up at Clifton, in 1798, by Dr. Beddoes, with huge reservoirs of gases for the use of patients.

The celebrated Humphry Davy, then just out of his apprenticeship, was appointed superintendent. Though not successful in the immediate object for which it was founded it was so in another sense; for here Davy made his masterly researches concerning nitrous oxide gas. In 1800 he discovered that, when inhaled, it produced a peculiar intoxicating effect, with irresistible propensity to muscular exertion, and often to laughter, whence its popular name of *laughing gas*. He also discovered its anæsthetic properties, and successfully inhaled it himself to relieve the pain of cutting a wisdom tooth. (b) He made numerous experiments with it on animals. In his account of these experiments there occurs this memorable and oft-quoted sentence. (c) "As nitrous oxide, in its extensive operation, appears capable of destroying physical pain, it may probably be used with advantage during surgical operations in which no great effusion of blood takes place."

Those desirous of pursuing the subject further should read his work entitled "Researches Chemical and Philosophical chiefly concerning Nitrous Oxide." Strange to relate, notwithstanding their completeness, nothing came of these remarkable observations. Their real import was not understood until nearly half a century later.

Dr. Hickman, in 1828, suggested the use of carbonic acid gas, in imitation of the experiments performed on dogs for ages, at the Grotto del Canale.

The modern practice of anæsthesia, though it may have benefited indirectly by these experiments, was not the immediate outcome of any of them; it originated to a large extent independently. The honour of making this discovery rests chiefly with three American doctors—Horace Wells, Charles Jackson, and William Morton.

One winter's night in December, 1844, a number of the inhabitants of Hartford, the capital city of the State of Connecticut, assembled to hear a lecture on nitrous oxide and other gases, from Dr. Colton, a well-known popular

lecturer, who tried the effect of the first-named gas on several of the audience. Among those present was Dr. Horace Wells, a dentist of that city. He noticed that a person under its influence sustained a severe injury of his leg without apparently feeling any pain. Dr. Wells was so impressed with this fact that next day he got the lecturer to give him the gas; and whilst under its influence he had a molar tooth extracted, without feeling the least pain. As he recovered from the effects of the gas his first words were:—"A new era in tooth-pulling." (a)

The modern practice of anæsthesia dates from this operation. Dr. Wells appears to have been unaware of Sir Humphry Davy's experiments. He found the peculiar intoxicating effects described by Davy due to mixture of the gas with the atmospheric air; for when precautions had been taken to exclude the latter, only anæsthetic effects ensued from its inhalation. (b) He gave the gas to more than a dozen of his patients, and with complete success. Elated with this good fortune he quickly obtained permission to make public trial of it at the Boston Hospital. Unfortunately, the bag was removed too soon, and in extracting the tooth the patient uttered a piercing cry. (c) The sceptical audience rudely hooted and hissed, and he was laughed at as an ignorant pretender. (d) Now, Dr. Wells was a modest and retiring man; he felt the insult deeply. Home he went mortified and in disgust, and never afterwards resumed his experiments in public. He soon fell ill from vexation, retired from his profession, engaged himself in stuffing and exhibiting birds, and in the sale of shower baths. Subsequently, he visited Europe as a picture dealer, then returned to America, became more and more unsettled in his mind, and finally died by his own hand in January, 1848. So the world ever rewards its greatest benefactors!

For a long time Dr. Wells' just claims as the discoverer of modern anæsthesia were ignored—indeed, we are only now beginning to do justice to his memory. He, at least, never attempted to make a secret of his great discovery, and to use it for his selfish ends. In a liberal profession it is no doubt more graceful to abstain from all exclusive rights, and to trust to that kind of reward which ought to follow a good reputation; but it must be admitted that such trust has too often been misplaced, and until the public manifest a more generous, a more just disposition, towards its benefactors, we have no right to complain of any one who desires to secure for his own family the benefits of his own invention.

"On making the discovery," says Dr. Wells, (e) "I was so much elated respecting it, that I expended my money freely, and devoted my whole time for several weeks, in order to present it to those who were best qualified to investigate and decide upon its merits, not asking or expecting anything for my services. I was desirous that it should be as free as the air we breathe. Judge, therefore, of my surprise after the lapse of many months, when I was informed that two individuals (Drs. Jackson and Morton) had claimed the discovery, and had made application for a patent in their own names."

We truly may apply to Dr. Wells the well-known words of Socrates—"Crito, we owe a cock to Asclepius, discharge the debt, and by no means omit it."

The use of nitrous oxide as an anæsthetic, for the time being, died with Wells; and the discovery was again in danger of being lost. Dr. Colton's praiseworthy efforts to reintroduce it were in vain until 1863; when he succeeded in getting a few practitioners to try it. Its use spread rapidly, so that in 1867—the year of the Interna-

tional Exhibition—he was able to visit Paris armed with a record of 20,000 administrations without a single accident. He met with very little encouragement from the Paris Faculty. However, in the spring of the following year, his apparatus was brought to London by Dr. Evans, an American dentist resident in Paris, who administered the gas before the staff of the Dental Hospital, and thus introduced the practice into this country. (a) At first, the most unreasonable prejudices were entertained against it, and several years elapsed before its use became at all general. Finally, common sense prevailed. It has now been administered over 20,000 times at the London Dental Hospital (b) and with but a single fatality. (c) At the Colton Dental Association of New York, it has been given over 100,000 times in that city without causing a single eath. (d)

Of all anæsthetics this is the safest, quickest, and least disagreeable. Unfortunately, with it insensibility can only be maintained for a few minutes, at the most. Hence its employment has hitherto necessarily been restricted to short operations such as those of dental surgery. Clover, however, used it as a precursor to the administration; and herein he has found many imitators. (e)

Recently, M. Paul Bert (f) has succeeded in overcoming the above objection by giving, instead of the pure gas, a mixture of it and oxygen gas, in the proportion of 85 volumes of the former to 15 volumes of the latter, under increased atmospheric pressure, in a special chamber constructed for this purpose. The necessity for the latter part of this provision arises from the fact that when the mixture of the gases is inhaled alone, complete anæsthesia cannot be produced, owing to the full complement of nitrous oxide (45 volumes to 100 volumes of blood) not being taken into the lungs during respiration. But under the above-mentioned increased pressure, sufficient nitrous oxide is inhaled to produce anæsthesia, and sufficient oxygen to prevent the supervention of asphyxia. Thus, prolonged anæsthesia can be maintained.

After many experiments on animals this method has been tried at the Paris Hospital by Pean and others; and with complete success. I have not yet heard of its employment in this country. Anæsthesia thus induced is quickly recovered from, and without any ill effects. It claims to be the safest method known, but all such statements are premature. Experience alone can decide this question. The requisite apparatus in its present form is too cumbersome and expensive for general use. Although in this respect, the invention appears somewhat crude, it is probably destined in its future developments to render great service to humanity.

CONSUMPTION VIEWED IN RELATION TO EVOLUTION AND MOLECULAR ENERGY.

By WILLIAM H. PEARSE, M.D.,

Senior Physician to the Plymouth Public Dispensary.

(Continued from page 444.)

As examples of stovism I may cite, Kate H., æt. 4, has phthisis of left lung. The mother is sunken across eyes, her nose unduly to left, alæ nasi still. She is subject also to cold shiverings between the shoulders and down the back.

Charlotte M., æt. 21, came for wasting, which has been going on for two years; has very slight physical signs on right supra-spinous region, has enormous amount of hair. Her mother and father each lost a

sister of phthisis. Her mother is a delicately built woman, with unduly oblique features toward the left; she had when young, and still has, a great amount of hair.

William L., *æt.* 21, died after about six weeks illness from phthisis; his mother has sunken line across orbits and root of nose, and large nails; about fifty years of age, "she has never needed a doctor."

Mrs. H., *æt.* 40, has been two years under treatment for phthisis; her sister, *æt.* 35, has wavy hair, the upper incisors bright translucent enamel, and are all gone laterally, the index finger nails not so fully developed as the others.

The series of successive individuals of a species or genera, show, if viewed from the narrow period of individual life, or from historic periods even, the law of "continuity" in the main; but the facts of "variation," in harmony and partship with cosmic evolution and progress, are ever present. "Continuity" contains the less obvious, but all important series of "variation." It cannot be unimportant for the physician to recognise the co-relations of phthisis with the more prevailing atavic variations of the body. In a familiar sense, the use of the terms "structure" and "function" are separate; but more profoundly, they are not separate, but are parts only, of one series. It may be worth while to illustrate the relation of the various stages and symptoms of phthisis to hereditary and atavic law.

Ellen L., *æt.* 38, came for "weakness, wasting and fluttering of heart." No decided physical signs in the chest; has been failing for a year; has much indigestion; burns at night; for six months past has had cold shivers down the back; had no child the first twelve years of her marriage. The right thumb, index, and middle nails hollow; the left same finger-nails hollow, but less so; hair in vast amount. All the upper incisors decayed when young. Her mother, and mother's three sisters, died of phthisis.

Mrs. S., *æt.* 38, has her nose markedly out of the mesial line, and to the left; the terminal cartilages unsymmetrical. Her child, *æt.* 10, has much strumous abscess of the neck. Viewing phthisis as a natural contained deviation of normal structure and parts, it is easy to observe its correlations with certain organs, segments, limbs, or nerve regions of the body, and to trace the "form" of atavism and heredity. It is not so easy to trace the same general "form" in symptoms, because that the series of pre-phthisical symptoms, although they have in the main a pretty uniform or generic course, yet they vary much in individuals, or in the minor circles of species. Pre-phthisical deviations in symptoms change also with the different ages of the individuals, *e.g.*, the symptom may be amenorrhoea from 16 to 18; after that indigestion may be the symptom. But although the pre-phthisical record in symptoms is less obvious than in organic forms, not the less it is easily recognised.

Mary D., *æt.* 46, unmarried, a fine country woman, aquiline nose; upper incisors not gone; had one child eighteen years ago; came for "weakness," sinking at epigastrium after food. Hands cold; feet always cold. Her two brothers—two fine men—both died of phthisis.

Mary H., *æt.* 21, a fine, well-nourished young woman, came for "weakness;" pain at epigastrium after food; "tearing pain over sternum;" cough; "I feel so weak when I get up in the morning, that I am only fit to go to bed again;" feet very cold at night; sensation of cold trickling down back; burns much at night; "could go all day without eating." No decided physical signs in chest. Right and left thumb, index and middle finger-nails very small and hollow. Nose, mesial; sunken orbital region; terminal cartilages broad and non-symmetrical. Hair coarse, and much of it. Five of her father's brothers died of phthisis.

Annie M., *æt.* 22, has end of nose sharp and thin and to the right; teeth not gone; "always have been subject to indigestion for many years, as long as I can remember;" menses not regular; no appetite; feels

extremely weak; feet cold at night; no physical signs in chest. Father and one sister died of phthisis.

Ellen C., *æt.* 28, has had pain at epigastrium and over sternum for many years after food; salted food and cheese agree best; "always shaking with the cold; feet dreadfully cold;" "I seem so weak, I have no strength to do anything;" "menses always were scant, now only a sign." Flat across eyes; hands immense and cold.

Rosa H., *æt.* 25, has had two children; came for "weakness;" "burns, and has cold sweats;" much pain at the epigastrium after food; has wasted lately; was once very stout; hungry at night, cannot eat during the day; cannot eat fats, but very fond of raw onions, pickles, and salt food. Hair in immense amount; eyebrows heavy; upper maxillary bone and nose slightly to right; terminal cartilage of nose unsymmetrical; no decided physical signs in chest. Mother died of phthisis.

John S., *æt.* 35, a fine man, with decided phthisis of both lungs, most marked in left; was quite well up to two years ago, when he began to shiver; this and the failure of appetite were the first things he noticed wrong. Hair great in amount; eyebrows very heavy; the hair on breast not great in amount, but on left infra-clavicular region is evolved in well-marked spiral curves. Feet very cold; "naturally cold after I go to bed." One brother died of phthisis; seven sisters alive.

Mrs. S., *æt.* 21, died of phthisis; her sister, *æt.* 16, has hæmoptysis. Father and mother alive; the mother has the line of eyes and bridge of nose much sunken.

These few cases, and I might greatly extend their number, will serve to illustrate the "form" of atavism and heredity in symptoms and structure. The different members of a family or series of generations, are units of an absolute chain. When phthisis, in its common meaning, shows in an individual, we must seek the "form" of the disease, not only in such case, but often in a long series of antecedent individuals and in different shapes or symptoms. It is important to state this, because the corollary is, that methods of prevention must be sought in commensurately wide generic conditions. But one may ask what name can we give to a series of symptoms, as weakness, wasting, amenorrhoea, burnings, cold neuroses, indigestion, &c., in their varied interappings; and still farther in their correlation with profound anatomical variations. As true parts of phthisis, they seem to point to a wide nerve involvement in relation to molecular "energy;" and lead us toward a generalisation connecting phthisis with the profound order or series of organic evolution itself. Surely, in the study of phthisis, and in any hope we may entertain for its prevention, these earlier stages have a great place; they are parallel to the first and earliest direction of variation in species. Just as these latter are deeply subject to physical and vito-physical environment, so we may be certain that the earlier deviations or "variations" of phthisis, may be very much under our control. But it is to close out philosophical Method if we are to view these interlapping deviations or variations as so many nosological entities or diseases! Although the phenomena of atavism, both in relation to the forms of different parts of the body, and in relation to function, are being constantly thrust on my observation, I am quite unable, either from "travelling instances" or from induction from numbers of examples, to perceive the exact order of the series.

Having thus glanced at the "form" of heredity and atavism, in relation to the complex and varied phenomena of phthisis, we may fairly further ask, Are there any anatomical correlations, or symptoms, or conditions which form part of the pre-phthisical series? It is as true in the involved and complex series of biological phenomena as it is in the more elementary sciences, "that any accession to our knowledge of nature is sure,

sooner or later, to make itself felt in some practical application." ("Prel. Discourse," par. 43.)

Anatomical.—The object in stating the anatomical correlations more commonly associated with phthisis is not alone for our immediate use in enabling us to put in a right prophylactic mode of life those who have a tendency to phthisis in the future, but to help us to a perception and knowledge of the deeper and wider "form" of this complex deviation, or disease. From the nature of our daily calling, in a yet profoundly unenlightened age in all that relates to biology and the presence of law in organic phenomena, we are ever in danger of being pushed back into the method of viewing diseases as so many entities or circumscribed existences; the immediate phenomena of disease are apt to impress us more than do their deeper and greater laws or conditions. Hence it cannot be unimportant to note the more fundamental correlations in Nature, which, however seemingly remote, are true parts of the entire phenomena of phthisis. We may well remember the injunction of Bacon ("Novum Organum," book ii., aphor. xxxii.): "For whatever withdraws the understanding from the things to which it is accustomed, smooths and levels its surface for the reception of the dry and pure light of true ideas."

That progeny do more or less resemble their sires proves that the varied and complex future of the individual must be differentiated in the spermatozoon; nor can we doubt but that the tendency to phthisis, &c., is even so early differentiated. But the organic evolution is not an absolutely closed or limited circle, but progressive; and although individual types of man are in the main already differentiated in the early ovum, yet as the ovum itself and all life are in absolute indivisible parthood and correlation with external nature and all-pervading "modes" of "energy," so it is clear from philosophical analogy that physicians can lessen or increase the latent tendencies to variation into phthisis by certain environment, (a) or treatment, or modes of life, and this *a priori* expectation is fully borne out by practice.

I have not been able to reduce the profound anatomical deviations to a definite order of series, but they involve markedly the superior maxillary and nasal bones, the clavicles, the circle or segments of the upper ribs, the hands, the skin system, &c. Nor, as before remarked, can we separate function from structure—the two are inseparably of one series. This is at once recognised in the ear and eye, in relation to sound and light undulation; and it must be as true in relation to the more complex vital processes. It is, however, convenient to group functional symptoms under approximative alliances and heads—ever, however, keenly looking for a recognition of their generic nature and common "form."

Just as we recognise in physics that "nothing is created, nothing lost," but that all the variety of phenomena are correlated interchanges of "mode" only, so in the vastly more complex organic realm do we know, *a priori*, that all changes, both of what we call health and disease, are ultimately correlated modes in an absolutely orderly series. Hence the causes or occasions of disease are not to be looked for mainly in single facts or phenomena, apparently near in time or place. It cannot, therefore, be unimportant to state the prevailing anatomical deviations and symptoms associated with the eventual phthisis. An approximative proposition may be fairly stated—that the evolutionary "energy" is deficient in those who eventually pass into phthisis, and that, although great variety of type is existent in them, yet these variations from the most perfect form and health are but oscillations in very constant circles.

I hope that the following sketch may help to indicate the profounder "form" of phthisis, and to show us

"how" (a) it is that at certain ages the vital "energy" and conservative power ceases in certain individuals, allowing even the flourishing of a bacterial "blight;" and further, that the recognition of the order and method of the "reversion" or devolution of vital failure may help us to a method of prophylaxis.

That any attempt at classification of phenomena, as variously more or less related to the bone, skin, &c., can never be absolute, because that the different parts of the human body are minor to one greater and general unity; and if this is true anatomically, it is more pressingly true functionally, and to the physician especially.

Symptomological.—In seeking to perceive the profounder "form" of phthisis, the earlier changes of function, or deviation from the series of prevailing vital rates of health, may be viewed in relation to the order, in time, of their occurrence, or as to their frequency; and in our present ignorance of the profounder molecular pathology, the two series—both as related to the stage or period of occurrence, and to frequency—must be studied in correlation with nerve distribution and segments, and with nerve centres. Very prevailing earliest functional deviations are in varied degrees and types of "weariness" and "languor." If it should seem to any mind that such seemingly simple phenomena have a small place in biological deviation, I may remind such one that the history of knowledge in all sciences shows that the greatest laws have been traced by the study of the most simple "instances."

Different patients have expressed themselves as follows:—"When I awake I am more tired than when I went to bed." "Easily tired." "Tired and worn-out in strength." "Tired easily without any exertion." "My strength is gone entirely" (not wasted). "I don't know what to do, I am so languid." "I often feel as though I could lie down and do no more." "Deadly weakness." "Weak one day, strong another." "Awful weariness; seem as if I should die from sheer weariness." A fine young woman, not wasted, whose nails were sunken and very undeveloped, said: "I am weak, very weak; I can hardly get about when I get up; I feel only fit to go to bed again." Not only are these phenomena prevalent and early in the series, but they are often of long duration before any other symptom is complained of, and before there is actual physical change in the lungs. Surely such phenomena point only to modes of vital "energy" and molecular vito-physics, and *a fortiori* lead us to expect remedies, even deductively reached, by the laws of Isomers, Correlation, and Continuity.

But it is wiser to draw a simple picture of Nature than to generalise too early, and therefore I will enumerate the other prevailing earliest deviations of the normal states of function:—

Cold, Neuroses, and Burnings.—J. S., male, *æt.* 35, with phthisis of both lungs, said that he was quite well up to two years ago; then he used to shiver. "This and the loss of appetite were the first things I noticed." I am naturally cold after going to bed." Eighty-four cases of phthisis said that they had suffered from cold feet at night; six said that they had not so suffered. Sixty "delicate" cases had suffered the same; fourteen had not. Cold feet, especially at night, is a most important early stage or symptom of phthisis—a true part of the series of the deeper deviations of nerve "energy" which so often ends in phthisis; a symptom very generally neglected, and with fatal consequences.

Such expressions as follow were made:—"Feet deadly cold at night;" "Feet awfully cold for years;" "Feet always cold for five or six years;" "One foot cold at night;" "Feet stone cold;" "Feet cold in all my growing up." Though less marked and less frequent than in the feet, this profound nerve lesion and failure is found in the hands; sixty-one of the "delicate" and

(a) Environment includes diet, because that the alimentary canal is truly an external part of the body.

(a) See Kingsley's "Madame How and Lady Why," for the meaning of the word "how."

in actual phthisis showed this symptom. We see this disturbance of "energy" involving the upper and lower spinal nerve distribution, and necessarily involving the inter-cranial parts and relations of the cerebro-spinal axis. It is for the philosophical anatomist to say how far these neuroses of the extremities are of allied series to the more vital disturbances of nerve function as seen in the indigestion, amenorrhœa, &c., or to the deficient innervation of lung growth, which constitutes the final phthisis. Out of these sixty-one cases of cold hands, thirty had hands of medium size; in twenty-six they were abnormally large; in four abnormally small; and one had extremely long fingers. One may remark here, although at present seeking to draw a sketch of function only, yet structure ever presents itself, even in its most fundamental regions—viz., in the nervo-osseous system, and that the correlation between the size of the hands and the disturbed innervation of coldness, seems to open to us some partial view of the actual order of the process of evolution. That a young man with abnormally cold and large hands should sometimes have a strong tendency to phthisis, is a fact in correlation with the profounder laws of the order of the evolution of the body and with the molecular "energy" of nerve structure.

Cold Neuroses in Varied Regions and General.—Patients expressed themselves as follows:—"Cold creeps down my back;" "Always cold; if I sit by the fire, cold shivers run down my back—cold behind, as the saying is;" "Cold feeling in back;" "Very cold at night;" "Cold, yet burning for a year or two;" "Suffered much from cold always;" "Shiver much with the cold" (not connected with cold weather). "Cold after any exertion" is a frequent statement, as though the supply of "energy" or its mode, were unstable. "Always cold, all the summer;" "A cold feeling creeps me—I don't know what to do with myself, spasms follows;" "Never warm—sleepy and cold on awakening." A correlation of these cold neuroses exists to heredity and atavism.

The mind fastens itself with avidity on such early deviations, for if we could grasp their true "form," we should probably be far on toward the method of compassing its wider course into phthisis. The study seems to open more on the side of molecular vito-physics, than even on that of anatomical evolution.

(To be continued.)

Clinical Records.

CASE OF PROLAPSE OF THE FUNIS.

Under the care of Dr. A. J. BLAIR.

A few weeks ago I had an interesting case of midwifery at Blackhill. The head and funis presented, and as this was my first case of funis I devoted a great deal of attention to it, in order that I might bring matters to a satisfactory close. The patient, Mrs. H., is a farmer's wife, and the mother of five children, all of whom are living. I saw her early, before the membranes ruptured, and while the long diameter of the child's head occupied a position which corresponded exactly with the right oblique diameter of the pelvis, a diameter which, as you know, it occupies in preference to either of the other two known as conjugate and transverse. The os was dilated nearly two-thirds, and easily dilatable, the vagina soft and well lubricated with mucous, and as yet she had not had a single pain in severity far beyond those that usually attend the approaching end of the first stage. As the readers of the *Medical Press* are aware a great deal has been said about the management of these cases of prolapse of the funis, and, as I thought I might have cause to impeach myself with having acted with undue precipitancy if I failed to deliver her safely by a method which some obstetrical writers regard as fraught with danger to the child, I was timorous enough to try in the first place to return the coil, if possible, by the most commonly advised plan of procedure, before I could feel myself justified in attempting to treat on my own responsibility the case before me in accordance with the method which crowned my efforts with success. Failing

in this endeavour to restore the cord to its normal *habitat*, I now gathered up and stored past the coil in the left sacro-iliac synchondrosis as far beyond the stationary head as I could, withdrew my fingers, introduced the long forceps, rotated gently the head, then, keeping the cord stationary with the fingers of my left hand, I used traction forcible enough to bring the spheroidal head beyond the margin of the brim, after which, keeping the forceps still in position, I roused, with a little ergot, the hitherto delightfully inactive uterus to action, and thus completed the case. The result was that I delivered the woman of a living child. Now, had I assumed an expectant attitude after being baffled in my attempt to return the coil, and had refrained from using the forceps until the cord had been brought under an amount of pressure sufficient to interrupt to an alarming extent the placental circulation, as it would have been when the powerful bearing down pains of the second stage had arrived, I do not think the chances would have been in my favour. I acted promptly, without pursuing blindly the reposition scheme of Brown, or the postural method of Thomas, of New York, and, without entertaining the slightest idea of turning; and as a result I succeeded in bringing to a successful termination, by a little skill and simple means, one of our most troublesome cases in midwifery. Perhaps I am open to censure for not having turned and delivered in that way. To have followed the stereotyped instructions of most midwifery text-books, would have been to do so, but the operation of turning in an uncomplicated case, such as mine was, would have been malpraxis in the extreme, notwithstanding, that the state of the soft parts and os, afforded me strong presumptive evidence that the operation could have been performed with ease by the person operating. Turning would seem to be a favourite operation with some, it has been performed frequently, and at a time it was almost universally held to be the only effectual method of dealing with these cases; but at the present day the other and much safer modes of operative procedure take the lead. The disuse, therefore, into which this once most popular operation of turning seems to have fallen, would go a great length in convincing me of its utter uselessness in cases of funis, nor am I the least astonished that it should be so far abandoned because the conversion of a head and funis presentation into that of a bootling or breach does not in any way lessen the risk to the child, for, as Professor Leishman says, "the operation being performed there is still the critical period of the passage of the head during which, although everything be done which skill can achieve, the child already enfeebled may succumb from the renewed pressure on the cord." In cases of turning we have not only to turn, but we have to apply our forceps as well, thus subjecting the mother to the double danger of turning and the use of the forceps, if there really be any danger in their use. If this be true, then the course pursued by me in this instance was the best possible course I could have adopted, at least, so says Madam Lachapelle, and Professor Leishman, in his most excellent treatise on the subject, strongly advocates the use of the forceps whenever they can be applied, thus asserting for them an evident superiority over every other means at our disposal. Nor is this all, no other operation in midwifery practice exposes the mother to less danger than the one I performed, and, if we are to believe the carefully compiled statistics of the late Dr. Churchill, no other operation reduces the risks of the child to a greater degree. Such then being the case, I am myself strongly inclined to plead for the forceps a superiority over turning, and over reposition of the cord, when the cord has to be maintained in position by means of an elastic catheter for the reasons, that turning is an operation much more dangerous to the mother, than the use of the forceps long or short; when performed, the life of the child is as insecure as before we commenced the operation. Turning is an operation always undertaken on behalf of the child, unless in complicated cases, such as placenta prævia, when we operate exclusively in favour of the mother, hardly ever troubling ourselves about the state of the cord, so alarming are the other symptoms, or if we do take into consideration the state of the cord it is only to admit it as of secondary importance, and the objection I would argue against reposition of the cord is that, it is sometimes practically impossible to restore the coil and keep it in position by means of an elastic catheter, besides the use of the catheter in a manner necessitates the removal of our fingers from within the uterus and vagina, and if you take away my fingers from about these parts you deprive me

of all power to manipulate accurately the presenting parts, and being so deprived, it must of necessity follow that death will result to the little creature whose life I had undertaken to save.

Ballynure, Co. Antrim.

AN ANALYSIS OF FIVE CASES OF SYPHILIS UNSUCCESSFULLY TREATED BY McDADÉ'S FORMULA.

Reported by J. W. MARTIN, M.D.

In the *British Medical Journal*, March 10th, 1883, p. 44, Dr. Marion Sims gave an interesting account of the use of the *Stillingia Sylvatica* (Queen's Delight), in the treatment of syphilis, in combination with other herbs. It was first noticed as used by the medicine men in the Creek Nation of Indians in Montgomery County, Alabama. The secret passed into the keeping of a coloured man named Lawson, belonging to M. N. D. Barnett, cotton planter, residing in Montgomery County; by him it was said to have been largely and successfully used in treating the hands on Mr. Barnett's and the neighbouring estates. Dr. George W. McDadé's attention having been drawn to Lawson's treatment of syphilitic cases, he managed to secure the formula, which Dr. Sims hoped might be called "McDadé's formula," the ingredients of which are as follows:—

R Fluid ext. of smilax sarsaparilla;

Stillingia sylvatica;

Lappa minor (Burdock);

Phyllocacca decandra (Pope root) a a 3ij;

Tr. of xanthoxylum carolinianum (prickly ash) 3j.

One teaspoonful to be taken in water three times a day before meals, and gradually increased to tablespoonful doses. Cure said to be effected in a few weeks.

In the *Therapeutic Gazette*, March 15, 1884, p. 110, vol. v., No. 3, New Series, Assistant-Surgeon John Godfrey, M.H.S., give a report of five cases of syphilis treated by him in the Marine Wards, Town Infirmary, New Orleans, with McDadé's formula. Beginning with 3j. doses, he increased them to 3ij. doses, and in one case to 3iij., the course extending over periods varying from eighteen days to one month. With the exception of a slight improvement in one case, the results were most unsuccessful and disappointing. The treatment in every case had to be changed for potass iodide. The changes being accompanied by rapid and marked improvement.

It is of course impossible to say if the drugs used were at fault, but it is fair to presume that such was not the case.

It is evident that further and more extended trials must be made with this plan of treatment before its claim for undoubted usefulness can be established, at the same time it would be unwise not to put it to further proof, as it is well known that uniform success or want of it, is not obtained by all experiments alike, and the very fact of its having been so favourably noticed by Dr. Sims, entitles it to most careful and respectful consideration.

ACADEMY OF MEDICINE IN IRELAND.

PATHOLOGICAL SECTION.

A MEETING of this Section was held at the College of Surgeons on Friday evening, March 28. Dr. CORLEY, Sectional President, in the Chair.

TWO EXAMPLES OF RECENT COLLES' FRACTURE.

Dr. BENNETT made the following communication: The specimens were examples,—the first of fracture without comminution of the lower fragment; the second, of comminution of the lower fragment, the result of impaction of the upper into the lower. Having referred to his paper read before the British Medical Association in Cork, 1879, the author showed the agreement of these specimens with those exhibited by him at that time. He dwelt particularly on the simple fracture as proving that even under the condition of extreme violence such form of fracture was possible; for instance, where the patient had fallen from the topsail yard of a vessel at sea to the deck. The author agreed that, as he had already shown

fractures without comminution of the lower fragment, with reciprocal impaction of the fragments, and lastly, fragments with complete shattering of the lower fragment, all were proved by post-mortem examination to be possible.

The PRESIDENT said he had seen a great many of Colles' fractures, yet he felt diffidence in expressing an opinion which was not in accord with that of Dr. Bennett, who had made fractures a subject of special study. But he thought that post-mortem specimens of this kind of fracture were not so valuable as might at first sight appear. The usual Colles' fracture resulted from a much less amount of violence than must have occurred in cases which ended fatally, and gave rise to post-mortem examinations. The former generally results from falls on the hands, and it was impossible to say that they were typified by such a case as Dr. Bennett had described, and which was attended with comminution of the lower fragment. The Colles' fractures most commonly met with were transverse, and (contrary to what the late Dr. Smith taught) were frequently impacted. He did not think their knowledge of this description of fracture was advanced by examples of fractures that had resulted from falls from third or topmost windows which were attended with much greater violence and injury to the bones than in the case of the typical Colles' fracture. For these reasons it would be always possible for a great deal to be said both on one side and on the other.

Dr. CROLY concurred with the President as to the value of the paper in reference to the present subject of fractures resulting from severe falls. He had had opportunities of making some dissections, and one of them had attracted so much attention at the Surgical Society that it was referred for examination to a committee, who reported that in their opinion the fracture was caused by penetration. It was a remarkable fact that the late Prof. Abraham Colles never made post-mortem examination of any cases of his fracture, and the description he had given of it had not been improved on by those who had had opportunities of making post-mortem examinations. The only thing learned from recent investigations was that there might be fractures with or without penetration—fractures comminuted, and also in different directions. Dr. R. W. Smith drew attention more than Prof. Colles did to the fractures that occurred close to the wrist-joint, and experience proved that the characteristic displacement of Pott that had penetration was not often seen, so that students who had not got it photographed on their memories might overlook fractures, and treat them as sprains. Any cases he himself had had were impacted fractures, and presented characteristic displacements, but with a total absence of crepitus.

The PRESIDENT remarked that Dr. Gordon, of Belfast, who was an authority on Colles' fractures, minimised the abduction of the hand, and declared that the amount of injury done to the ulnar extremity and to the external lateral ligament was not much. Dr. Bennett's case, and also that referred to by Mr. Croly, showed that that view was erroneous. The styloid process was torn away, showing that the amount of injury to the wrist was great.

Dr. BENNETT, in reply, observed that conclusions could not be drawn, at least without qualification, either from ordinarily-obtained specimens or from dissections in which there had been great violence. The specimen he had shown proved that even when the violence was of the greatest description, it was possible to have a Colles fracture without impaction, and with the lower fragment perfectly unbroken. He had shown that in ordinary injuries produced by falls in the street, &c., comminution occurred in two cases out of every five. If his argument were right, and he saw no reason to doubt the validity of it, comminution was the result of impaction. Dr. Croly's specimen proved the existence of the impaction which Prof. Smith had denied. In nearly all the specimens preserved the radius only was kept, and in consequence of the absence of the ulna he had no statistical information to offer as to the number in which the styloid process of the ulna had been torn off. Nevertheless, that occurrence was common, and Malgaigne had figured it in his plates, and represented detachments of the ulnar styloid as a typical part of the injury. He himself had many specimens in which both ulna and radius were preserved, proving that, although the ulnar styloid was often torn off in the fracture, its lesion was not by any means a necessary feature of the injury.

MITRAL OBSTRUCTION WITH COMPLICATIONS.

Dr. QUINLAN brought forward a case of mitral obstruction

with vegetation in the passage leading to the aortic valves and cardiac hypertrophy. He said it was taken from the body of a girl, *æt.* 20, who had a history of rheumatic fever with apparent endocarditis, but without any record of treatment for the latter. During life she exhibited general serous engorgement of the body, congestion and oedema of the lungs with dyspnoea, and constant attacks of cardiac asthma. There was presystolic murmur at the apex of the heart, and at the base there was also a slight systolic murmur. The second sound was perfect and there was no visible pulsation. The pulse was thready and weak. There was a great increase in the area of the cardiac dulness and a powerful apex impulse. These symptoms caused a diagnosis of mitral narrowing with some vegetations in the passage leading to the aortic valves along with hypertrophy of the heart to about double the natural size. There was great oedema, particularly in the right side, a circumstance which was attributed simply to dextral decubitus. During the last fortnight of life the large branches of the vena cava swelled enormously, evidently owing to the formation of a fibrinous clot in the right auriculo-ventricular opening, and during the last few days there was great oedema of the lungs, and death was very lingering, a circumstance which was attributed to the formation of a clot in the mitral orifice. The post-mortem examination showed that the heart was much hypertrophied and weighing fourteen ounces. The mitral orifice admitted one finger tip only, and the valves were studded with large hardened vegetations. There were similar vegetations in the passage leading to the aortic opening, but these valves were competent, as shown by the water test. Both auriculo-ventricular openings were occupied by coagula, that in the right leg white fibrinous, and that in the left sanguineous with some white fibrine. There was also slight pericardial effusion.

Dr. STONEY asked on what evidence Dr. Quinlan concluded that the clot on the right auriculo-ventricular was an *ante-mortem* one.

Dr. QUINLAN replied that the patient's difficulty of breathing before death became very great, and the congestion of the bronchus and the vena cava became unceasingly great and at last tremendous. He believed these symptoms were caused by the clot.

Dr. HENRY KENNEDY said that fifty or sixty years ago the late Dr. Hartz published a paper showing the possibility of diagnosing the *ante-mortem* clots.

TUBERCULAR DISEASE OF THE THUMB.

Dr. BENNETT showed a specimen of tubercular disease of the thumb, consisting of half the ungual phalanx of the thumb of an old woman, which he removed last summer. There was an ulcer beneath the thumb nail. She had no glandular disease elsewhere, or trace of trouble in the axilla or any part of the arm. The only thing was the ulcer which had lasted for five or six years, and for which she had been treated in almost every hospital in Dublin, every means being used, short of amputation. The best attempt at diagnosis he could make was that it was the ulcer of cicatrices of Hawkins and Margalli. He believed that it originated with some form of suppuration, and that it then progressed and finally resisted all treatment. It was watery, excavated, and extremely sensitive at the edges, and when a probe was passed it could be felt that the bone was exposed, though not naked. There was no rough or carious bone. Other treatment having failed, and the pain being such as to oblige the patient to give up her occupation, he amputated the extremity of the thumb, and the case had since done well. Dr. PURSER had examined the specimens, which presented the characters of well-defined tuberculosis.

Dr. PURSER said the reason why the specimen was called tubercular ulcer of the thumb was for want of a better name. By tubercular was meant a growth containing some peculiar micro-organism. In the present specimen he had not looked for a micro-organism, but the characters of the growth as discovered by an ordinary examination were those of tubercle with certain differences. In tubercle there were numerous little groups of cells, each constituted with a grand cell in the centre, and these cells had a peculiar form of protoplasm, characteristic of tubercle only. In the present case some of the small cells were epithelioid, and others lymphoid; but there was no evidence of causation, and that was the point in which the case differed from ordinary tubercle; but the growths themselves had quite the appearance of recent tubercles.

Dr. BENNETT said that, although he had not at first recognised the character of the ulcer, he concluded that amputation was the best course. This, however, was the first sample of the disease that he had seen. Tubercular and scrofulous diseases affected the bones both of old and young, and were liable to be mistaken for malignant diseases, but a superficial tuberculosis existing on a surface for five or six years, and causing absorption of the bone by its pressure were facts quite new to him.

MAMMARY TUMOUR.

Dr. BENNETT read for Dr. H. MacNaughton Jones a communication on sectional and microscopic drawings of a mammary tumour removed from a patient, *æt.* 40. The tumour had been quiescent for some years. Of late it commenced to grow more rapidly and there was occasional pain. The general health was otherwise good. The tumour was hard and lobulated. There was slight retraction of the nipple. One or two axillary glands were enlarged. The entire breast, with the affected axillary glands, were enlarged. The diagnosis was uncertain before operation as to the nature of the tumour. The sections, well-shown on the drawing, appeared rather to confirm the view that the tumour was of adenocarcinomatous nature, and not, as was thought, scirrhus. The cystic type was well seen. The complex character of the tumour rendered its histological differentiation difficult, save to a very experienced histologist. The cells filling the tubercles and sacculi were very small, and were not heterologous. All preserve the regular circular-outline. The termination of a duct crowded with cells was well seen in drawing No. 1. In parts, the tumour had the appearance of a fasciculated sarcoma or fibroma. The tumour was removed last August antiseptically. The wound healed without the formation of pus, and the patient was going on well. The painless nature of the growth, and the very slow progress were against the supposition of carcinoma, but the microscopical appearances when the tumour was cut into, were in favour of scirrhus. The sections were made by Mr. George Walton.

The specimens exhibited were decided by several members of the Academy to be examples of scirrhus carcinoma.

The Section adjourned.

LIVERPOOL MEDICAL INSTITUTION.

THE Thirteenth ordinary meeting of the Session was held on Thursday, April 17th, the President, Dr. GEE in the Chair.

SPECIMENS EXHIBITED.

Dr. BARRON: 1st. Specimen of osteo-arthritis of carpus and hand from aged female, showing eburnation of the articular surfaces of several of the carpo-metacarpal and phalangeal joints, with the production of osteophytes, widening and flattening of the articular surfaces and the production of great deformity; 2nd. One internal cuneiform bone which consisted of two vertically superposed halves, which had been united together by two articular surfaces and an interosseous ligament. The development of the internal cuneiform from two centres is extremely rare.

CANCER OF BLADDER, ACCOMPANIED BY CALCULUS.

Dr. ALEXANDER showed an enormously thickened bladder from which a stone had been removed four days before death, by supra-pubic lithotomy. The specimen was taken from a man, *æt.* 40, a watchmaker, who had been successfully lithotomised when 19 years of age. He enjoyed fair health from that time until a few months ago when he began to fail. During the last few weeks he had become dull and apathetic, suffered from incontinence of urine, and from internal pains. When Dr. Alexander saw him, the bladder could be felt as a hard, irregular mass, pressing upon the abdominal wall above the pubes. A stone was detected by the sound, but it was fixed at the upper part of the bladder and so surrounded by hardened tissue that its size could not be clearly ascertained. Cancer was not suspected, the kidneys were evidently disorganised, and operation contra-indicated. When the patient became worse the friends pressed for an exploration, and under the circumstances the supra-pubic incision offered the best region for exploring the bladder. The stone was with some difficulty removed, but the downward course of the patient seemed to be unaffected. The cancer was evidently the infiltrating variety, and probably arose from the irritation of the calculus. It affected nearly all the bladder except a

small area round the right ureter, one kidney was completely destroyed and the other partially.

**SACCULATED FEMALE BLADDER CONTAINING A STONE
—STONE AND SAC REMOVED BY OPERATION.**

Dr. ALEXANDER showed that this was the fourth case on record, Dr. Gibson, Sir Henry Thompson and the late Mr. Lyster, of Liverpool, removed the calculi in the three cases. In none of the cases was the sac removed as in this one. The tumour formed by the sac and its stone was about the size of a pigeon's egg, it protruded from the vulva and arose from the vagina by a narrow neck, into which a sound could be entered by reversing its beak just as it reached the bladder. The tumour was complicated by prolapse of the anterior vaginal wall, and produced pain in walking and in evacuation. It had existed probably for six years, but only troubled her during the last two. The stone was removed by cutting into the tumour over the most prominent part. Three weeks after, the sac being still large and the prolapse troublesome, the roof of the vagina was completely removed, the sacculation of the bladder ligatured at its neck like a hernial sac with strong catgut and the sac removed. The cut edges of the vaginal walls were united by silver wire sutures in the middle line. No troublesome symptoms followed, and the patient was discharged quite cured.

Mr. REGINALD HARRISON remarked that cases of encysted stone in the female bladder were of extreme rarity. He would like to know if Dr. Alexander was certain of the precise situation of the cyst? He saw a case in association with the late Dr. Lyster, in which the cyst was not in the bladder, but in the floor of the urethra. A stone was removed about the size of a walnut. If Dr. Alexander's after treatment had been adopted, the course of recovery would have been less tedious.

Mr. RUSHTON PARKER related a case of

**OLD DISLOCATION OF SHOULDER, FOLLOWED BY ANEURISM
AND LIGATURE OF THE SUBCLAVIAN ARTERY.**

The patient was a woman, *æt.* 36, who had had a fall and fractured the forearm. This was set by a surgeon in the town, and the patient at the time made no allusion to anything being wrong about the shoulder-joint. She was admitted into the Royal Infirmary some time after the fracture had united, and six weeks after, the dislocation was reduced, very considerable force being required to effect the reduction. The head of the humerus passed into its position without any noticeable sign, except that the shoulder resumed its normal shape. Six days afterwards there was considerable ecchymosis and a pulsating swelling. From the situation, he concluded, that these arose from aneurism of the sub-scapular artery. The swelling increased in size, and he decided to ligature the subclavian artery. This was done, and in due course, the patient recovered and was discharged.

HEMIOPIA.

Mr. RICHARD WILLIAMS related the case of a young gentleman, a solicitor, *æt.* 22, who had consulted him on the 10th December, 1883, for defective sight, and who thought he had strained his eyes in studying for his examination, which he had just passed. With the exception of an error of refraction there was nothing abnormal in the eyes. A scotoma was discovered, which soon developed into right homonymous hemiopia. With the exception of some pains, apparently neuralgic, about the head, there was no other symptom, either general or local. The patient was seen in consultation by the President, and subsequently by Dr. Hughlings-Jackson, who thought the case one of central embolic lesion in the region of the optic thalamus. Shortly after, severe headache and vomiting came on, with derangement of the sense of smell, and loss of power in the right side. The intellectual faculties became affected, memory being very defective. All these symptoms became aggravated, and the patient died on the 1st March, 1884. There was no history of syphilis. No post-mortem examination was made as the patient lived a long way in the country. Two interesting questions arose as to the nature and the seat of the lesion, and Mr. Williams thought the opinion of Hughlings-Jackson must be set aside, in view of the subsequent development of the symptoms. He believed the case to be one of rapidly growing tumour originating in the substance of the left optic tract, producing in the first place a scotoma which developed into hemiopia as the whole thickness of the tract became involved, and then by extension to the roots of the olfactory nerve anteriorly, and to the crus cerebri above, the other symptoms already men-

tioned might be explained. The absence of optic neuritis in the early history of the case was probably due to the absence of pressure, and that symptom might possibly have made its appearance along with the other signs of pressure during the last three weeks of life, after the patient had been withdrawn from observation.

DISCUSSION ON DR. CATON'S PAPER ON PNEUMONIA.

(Concluded from page 401.)

Dr. W. WILLIAMS said that his mortality from pneumonia at the Liverpool Southern Hospital had been 40 per cent. He had seventy-two cases since 1875, with twenty-nine deaths. Regarding the question of pneumonia being epidemic, it was remarked that the period of high mortality at the Northern Hospital was not coincident with that at the Southern. He thought the mortality depended much on the length of time elapsing between the commencing of the disease, and admission into hospital. He had seen no evidence of contagion. An equable temperature (63 or 64 deg.) was important in the treatment.

Dr. BOSTOCK had been living in Kent during last summer, and had seen a series of cases that favoured the view of infectiveness. A father, mother, and five children well fed and clothed, dwelt in a small house, outside of which was a cesspool. The only drain in the house was in direct communication with the cesspool. The weather was hot and dry, and the foul smell of the cesspool was brought into the house through the drain. A child was taken ill with high temperature and developed pneumonia, and within three weeks the whole of the five children contracted the disease. All recovered. He thought the disease in this instance was from a septic source. There was one difficulty, however, that required solution. Were there then two forms. One from sepsis and one, the old-fashioned form, from "cold?"

Dr. CARTER said there appeared to be two main propositions in the paper—1st. That at certain periods the type was especially fatal, and 2nd. That this fatality, if not all, was principally, due to a bacterium. He should be inclined to question both propositions. He should say it was rather non-fatal in extra hospital practice, but more fatal in hospitals, and especially in sea-port towns. Besides, the habits and general condition of the classes of patients should be taken into account. Out of 100 of his cases, 40 were sailors and 27 labourers. The paper gave no report of the length of time between the first rigor and admission into hospital; this was an important point as Dr. Williams had pointed out. It was generally about a week and often more. He had had 101 cases with 25 deaths, 1 died before the patient was seen by himself, 4 occurred within 24 hours of the patients' admission, and 6 more within 48. A fall in temperature coinciding with a rise in the pulse, he looked upon as a bad symptom, the same when delirium came on late. He did not see his way to accept the theory of infection, the disease was not communicable, it was limited to one part of the body, and it might occur twice in the same individual, its onset was often very sudden, it appeared never to be communicated to those who made post-mortem examinations.

Dr. ARCHER thought intemperance was an evil factor as regarded recovery. Many pathologists seemed going mad at present on micrococci and bacilli, he did not think they had anything to do with phthisis or pneumonia; they might with the specific fevers.

Dr. ROBERTSON had never observed any infectiousness in the disease at the Liverpool Workhouse. It had not been proved, that the organisms met with in the disease were not the product of decomposition. He practised blood-letting in selected cases.

Dr. BARR did not believe much in the influence of micrococci.

Mr. HAMILTON complained that so little had been said about the most important points in the discussion, viz., the micro-organism and their importance. So much depended on the accuracy of the views at present put forth. He thought that the facts brought to light by the best microscopists showed that pneumonia had a septic origin, if this were proved it would bridge over a difficulty. The fact that pneumonia was not infectious did not prove that it was not of infective origin, as was the case in phthisis, which was infective, but perhaps not infectious.

Dr. DAVIDSON thought it was a pity that treatment had drawn the discussion away from the etiology. Pneumonia was different from other inflammations from cold, from bronchitis which had a more gradual rise and deservence.

terminated suddenly, often by crisis, this, and the fact that, five cases occurred within so short a period was an argument in favour of its being an infective disease, not infectious. There was more in pneumouia than mere irritation from a cold.

Dr. WORRAL and J. STOPFORD TAYLOR also spoke, the latter mentioning three cases that had occurred in such a manner as to lead to the belief that the disease was sometimes infectious, after which

Dr. CATON replied, and said he thought there might be two types of the disease—an epidemic and a sporadic, as there certainly were in the pleuro-pneumonia of cattle—one infectious, and one not so.

Special Articles.

THE 13TH CONGRESS OF THE GERMAN SOCIETY FOR SURGERY.

[FIRST NOTICE.]

THIS Congress was held as is usual in Berlin from Wednesday to Saturday in Easter week (April 16th to 19th), under the presidency of Excellenz von Langenbeck. Great numbers of the leading spirits of German surgery are always attracted by this Easter gathering, and the present occasion was no exception to the rule. Some who on former occasions graced the meeting by their presence were unfortunately absent. Amongst this number were Bardeleben, Thiersch, of Leipzig, and Billroth. Volkmann was elected vice-president. An attempt was made to postpone the time of meeting for subsequent years to the Whitsuntide holidays, but the attempt failed. Another resolution was, however, carried, viz., that the Society elect distinguished surgeons as honorary members. The number, however, will be limited to twelve.

The papers and discussions were quite up to the average, and cannot fail to leave their mark on the practice of the near future. The following brief *resumé*, for which we are indebted to the fuller report of the enterprising *Deutsche Medizinische Zeitung*, will give an indication of the direction of German thought in the domain of surgery.

The first paper was by Dr. F. Neelson, of Rostock, "How do the Clinical Conceptions of Sepsis, Septicæmia, and Pyæmia adapt themselves to the Newer Experiences of Pathology?" The paper professed to explain that wound diseases arising from the admission of impurities from the atmosphere, dirt, &c., when they are not specific diseases, as erysipelas for example, were a combination of three processes, viz., of putrid intoxication, of inflammation at the seat of inoculation, and of the growth and development of bacteria in the blood. These three together gave rise to the affection called septicæmia. This compound septicæmia might be modified by spreading along the lymph- and blood-channels to remote parts in which metastatic inflammations produce an affection that bears a resemblance to pyæmia. It was not pyæmia however, this being a disease *sui generis* like variola or glanders, which require no wound for their origination.

Herr Küster, of Berlin, followed with a paper on "The Employment of Sunk Sutures, particularly in Plastic Operations." Such employment of sunk sutures is evidently, in the opinion of the author, a step towards the attainment of the ideal in surgery. The problem of the day, as he says, is the discovery of some method of so putting up a wound that without further touching or change of dressing healing shall take place. The method proposed by Herr Küster is recommended by him as a step towards the solution of the problem, and thus towards the attainment of his ideal. It consists in closing wounds by layers of sutures, i.e., sutures at different depths so that pressure as nearly equal as possible shall be exercised over every part of the wound. He particularly recommends it for perineal operations. In the discussion that followed Eschmarch, Schroeder, and Mikulicz confirmed the statement of the author that, by his method the formation of pockets was avoided, and in many cases a drainage-tube rendered unnecessary.

König, of Göttingen, read a paper on the question, "Whether the Indication for Resection in Tubercular Joint Disease in View of the Increased Danger of General

Tuberculosis from the Joint Affection was Well Founded?" The writer had observed cases in which general tuberculosis had supervened on tubercular joint affection, and he considered that the question should be answered affirmatively.

Herr Cramer, of Wiesbaden, read an account of an exceedingly interesting case of "Ferment Intoxication caused by a Blood Cyst," in which a patient, a young woman, for two years suffered from acute symptoms, persistent fever, cough, diarrhoea, abdominal pains, insomnia, loss of strength, &c. Finally a small fluctuating tumour was discovered in the left thigh, the removal of which was recommended by Langenbeck who was consulted on the case. This tumour was accordingly removed, and "at a stroke" all the symptoms disappeared.

Herr J. Wolff, of Berlin, read a paper on "The Law of Transformation of the Internal Architecture of Bones in cases of Pathological Change of the External Bony Form," in which he showed that the trabeculae of the long bones were arranged in the lines of greatest resistance, and that when disturbance of these lines had taken place from fracture or disease the arrangement of the trabeculae became altered to suit the new requirements.

Herr A. Bidder (Berlin) read a paper giving particulars relating to a tooth that had been extracted and re-implanted, and another on an improvement in a knee extension apparatus.

Herr Schede showed a splint for the gradual flexion of the knee-joint.

Herr Wagner read a paper founded on six cases of "Dislocation of the Cervical Vertebrae," four of which recovered.

Herr Küster followed with a "Case of Fracture of the Odontoid Process with Compression of Spinal Cord." The case was specially of interest from a medico-legal point of view. The patient was a girl, 18 years of age, who was seized by the hair by her mistress and dashed violently against a beam. On the same day she was seen walking in the street. In the evening she complained of pain in the neck and went early to bed, on attempting to rise the following morning she fell with her head against the commode. On being removed home, a distance of 8 miles, symptoms of compression came on. The assault was the ground of a trial on which the experts examined could not agree as to the injuries sustained, some not believing that the patient could have walked after the assault if the injuries had been such as they were said to be by Herr Küster. The writer himself sought to reconcile her walking after the receipt of the injuries, not to an incomplete fracture, but to the symptoms remaining in abeyance until compression took place some time during the night succeeding the assault. He then read a paper on "A New Method of Amputation of the Middle of the Foot."

Herr Grawitz (Berlin) followed with a paper on "The Development of Tumours of the Kidney from Separated Particles of Supra-Renal Capsule." He remarked that the nodules (knoten) met with in the kidney were variously named in literature until at last the designation adenomata became the one in force. These adenomata were small, mostly cortical, and of significance in relation to their pathogenesis. The writer was of opinion that they generally had their origin in small particles of supra-renal capsule which had wandered and become embedded under the renal capsule. In support of the correctness of this view he offered the following arguments:—1st. That detached fragments of supra-renal capsule tissue are frequently present in the kidney structure, and with such frequency that the tolerably frequent occurrence of these small tumours can be explained by them; 2nd. That these separated particles correspond in their situation to that in which the small struma nodules are met with; 3rd. That the kidney tissue itself is not generally in a position to afford such products; and 4th. That the structure of these small struma nodules corresponds histologically to the growths met with in the supra-renal capsules.

Herr Credé, jun. (Dresden), showed a young man from whom he had removed a circular goitre. The growth completely encircled the trachea and œsophagus so that the two ends lapped over each other behind for a distance of about 1 c.m.

Herr Baumgärtner showed some similar preparations, the growth in each case entirely surrounding the trachea.

Herr Credé then exhibited a patient from whom the spleen was removed in 1881. The man, a mason by trade, was

quite well and followed his occupation. No swelling of lymph glands had taken place.

Herr V. Haeker, of Vienna, then showed a primary sarcoma of the spleen removed on the 20th of March by Prof. Billroth by laparotomy. The patient made a good recovery. At the operation adhesions of the tumour to intestine were met with at the hilus, some were separated and some ligatured and then separated. The artery and vein were isolated, secured by double ligature, and separated. The pancreas was also partially adherent, and a portion 3 to 4 c.m. in length was removed along with the tumour. No disturbance followed the removal either of spleen or of portion of pancreas.

Herr Albrecht, of Brussels, read a paper on the "Morphological Significance of Clefts of the Jaw, Lips, and Face."

Herr Neuber (Kiel) demonstrated a new method of hip-joint and knee resection adopted in the Kiel Clinio, and also an improved mode of suturing the divided ends of intestine by means of a tube of decalcified bone, which disappeared in a few days.

Herr Volkmann exhibited a boy whose hip-joint had been resected. The boy limped, but he had been able to walk long distances after the operation. Movement had not been so perfect in this case as usual owing to suppuration.

Herr Uhde mentioned a case of V. Langenbeck in which the result had been so perfect that the patient walked as well as any other man.

Herr Baumgärtner (Baden Baden) followed with a paper on "*Cachexia Strumipriva*." The paper contained a report of 19 cases in which goitres had been removed by operation; of the 19, 3 were dead; of the remaining 16, 10 were partial extirpations; of the remaining 11 (?) cases of total extirpation, four somewhat late plainly showed symptoms of illness which had been described by Kocher under the name of *cachexia strumipriva*. The first case was that of a girl, 16½ years of age, who a year after total extirpation showed certain external changes. She had a puffed up face and a certain inertia of bodily movement and thought. These symptoms became more marked in the course of the next six months, with difficulty of breathing superadded. Paralysis of the left vocal cord was demonstrated before operation. Some improvement showed itself after operation; after about one year complete paralysis of the abductors came on, so that tracheotomy was called for. A second patient, 56 years of age, also showed after operation a certain feebleness of thought and slowness of speech. The larynx was normal before operation, but about six months afterwards difficulty of breathing came on, and eighteen months after operation, tracheotomy was demanded. A third case was that of a young woman, 23 years of age. About six months after operation puffiness of the face and eyelids came on, with stiffness of the hands, but no alteration in power of locomotion or speaking. Eight days after operation there was complete aphonia (paralysis of abductors), but after treatment by means of the induced current (40 sittings) the voice was restored. The last case was that of a girl, aged 23, in whom the tumour was the cause of dyspnoea, after operation symptoms somewhat similar to those present in the three preceding cases showed themselves. In the remaining cases no symptoms of innervation of the larynx developed.

Herr Bruns (Tubingen) read a communication on "Sublimate Dressing with Wood Wool."

A description of the dressing and its mode of preparation have already appeared in our columns (p. 173, vol. ii., 1883), so that nothing further is required on these points. The speaker stated that from Jan., 1883, to date, he had employed the dressing in 557 bloody operations, amongst them 48 amputations and exarticulations, 44 resections, &c. Of the cases operated on, 10 died, but none in consequence of treatment. Erysipelas appeared once, and trismus once. A large percentage of the cases healed by first intention. Of the 48 amputations, 37 were of the limbs, and of this number 32 healed by first intention. The process of repair lasted from 18 to 23 days. Of 30 struma-operations, 25 healed by primary intention; three of those healing by granulation were cases in which there was considerable deficiency of cutis. Of 24 cases of resection of the knee-joint and extirpation of capsule 21 healed by first intention. In no instance was it necessary to change the dressing before the end of the first week. If the discharge was profuse a smaller pillow of the wool was laid over the first. He thought the surprising simplicity of the

dry dressing would be specially useful in military surgery. Lister had already spoken favourably of it.

Herr Schede remarked, in reference to the extraordinary power of sublimate over erysipelas, that the favourable results of sublimate dressing made public by him two years ago were attributed to sheer luck, but that this luck had continued, and that with an average annual admission of 4,000 sick into hospital and a daily average of 600 beds occupied, not a single case of erysipelas had been seen arising in the hospital, except some cases of erysipelas of the face that had nothing to do with the dressing.

Herr Mikulicz (Cracow) then read a paper on "Some Modifications in Antiseptic Treatment." He thought the results achieved already were such that essential improvement was scarcely to be expected. The modifications, therefore, could only be in the direction of simplicity. He would first speak of the spray. Most considered that the spray was done away with, but its defenders were of opinion that in good hospitals septic germs were so excluded that infection could no longer take place, but that in a bad hospital the evil results of leaving off the spray would soon be shown. The speaker was in a position to speak upon this point. In Cracow the sick were treated on the ground floor of an old dwelling-house that, for seven years had been used as the maceration room for anatomical preparations. The house stood upon an absolutely malarial soil, so that in the early part of the year a number of people always sickened of it. He had 21 beds, but these were always occupied by from 30 to 35 patients. The arrangements were so bad that it happened in the summer time that he had neither a clean towel nor a fresh compress that he could lay his hands on. Moreover, there was but one assistant. He began in fear to operate without the spray, but he was quickly convinced that it was unnecessary, even under these unfavourable conditions. He divided his operations into two classes—(1) one in which the wounds could be completely closed in, and (2) one in which the wound had a connection with a cavity lined by mucous membrane. In the first class were 123 major operations: 2 died, one after extirpation of a very vascular tumour in the neck, the second after amputation of the breast, of sublimate poisoning. The others healed: in 113 the course was aseptic throughout; in 8 it was disturbed. The second class included 57 major operations: all the patients recovered under treatment by iodoform. During the whole year only one slight case of erysipelas was seen, and no patient died of sepsis.

With regard to sublimate, as soon as it came into contact with the secretion from a wound, it coagulated and formed an albuminate of mercury, which possessed quite other antiseptic properties. He had experimented by adding sublimate to bloody water in certain proportions; he came to the conclusion that in a solution of 1 to 2,000 the process of decomposition was not influenced, and that a proportion of 1 to 1,000 was required to prevent the development of bacteria. Decomposition was completely kept in check only when the proportion was raised to 1 to 400 or 500. He thought sublimate was of special advantage only when it could not be rendered inert by albumen, but when it came into contact with wound secretions it was no better than carbolic acid. Under certain circumstances sublimate might have an increased value from its not being so fugitive as carbolic acid. It was disagreeable, absolutely unsuitable for instruments, and perhaps injurious to the surgeon.

The kind of dressing he considered of little importance, as when the wound was covered by a layer of iodoform gauze it mattered little what was placed outside. Even the decomposition of the secretion exercised no influence on the wound. As to the resorptive power of dressings, he thought the investigations were far too minute. He himself used shavings stirred in a solution of tar until they became of a nut-brown colour. In conclusion, he expressed the conviction that it was a matter of more importance *how* than *with what* you dressed.

THE post of health officer to the town of Calcutta is now vacant, and will not be filled up before the 15th July. The salary is Rs. 1,250 a month, rising by annual increments of Rs. 50 to Rs. 1,500, for which salary the incumbent will be required to devote his whole time to the work of the Corporation.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, MAY 21, 1884.

THE DECISION OF THE COUNCIL OF THE ROYAL COLLEGE OF SURGEONS OF ENGLAND.

CONFORMABLY with our prediction of the course that would be pursued by the Council of the College in respect to the resolutions submitted to it from the general meeting of Fellows and Members held on March 24 last, a defiant reply to the just demands formulated at that meeting has issued from the Council. In a certain sense this is satisfactory, inasmuch as it amounts to a formal declaration of war between the ultra-conservative members of the present Council, and those to whom, in right, they owe obedience; and it will serve to render any future misunderstanding of the selfish policy of existing authorities wholly impossible. Further than this, however, it must lend irresistible force to the demand for reform, by showing in a clearer light than any other occurrence could, to what lengths the majority of the Council are disposed to go in the exercise of arbitrary powers assumed by them to be part and parcel of their official rights. In effect, they say to the eighteen thousand odd of Fellows and Members, "We have listened to your proposal that we should agree to your exercise of privileges you have hitherto been robbed of, and though we do not pretend to contest the justice of the request, we do not for a moment intend to resign into your hands any part of the power we have so long enjoyed improperly, and which we shall continue to use or abuse at our will and

pleasure." This is no unfair or uncalled-for description of the attitude assumed by the Council; and we repeat that it is even fortunate that its intentions have been so explicitly explained, for nothing now remains to prevent the carrying out of the measures destined to demolish the tyranny which such action exhibits.

As regards the resolution, number three, declaring that "in the opinion of this meeting, there should be an annual meeting of Fellows and Members, at which the annual report of the Council should be presented, received, and adopted," a less sweeping condemnation was uttered; and it was decided that an annual meeting of Fellows and Members should be called, a report of which shall be presented to the Council. This is an ingenious, but at the same time most transparent, turning of the tables; the report of the meeting is to be presented to the Council, in place of the report of the Council being presented to the meeting; and in view of the circumstances under which the resolution thus framed has been arrived at, it is not possible to look upon it as anything other than an insult to the petitioners. It places the latter in a position of subserviency unique in the history of corporations; it tacitly confirms to the Council an extension of the powers now arbitrarily abused; and while ostensibly yielding the point of annual meeting it makes provision for subjecting the business transacted at such meeting to the revision and approval of an irresponsible and unsympathetic executive. Fellows and Members will not hesitate to describe this latest exhibition of presumption in terms sufficiently forcible to show their appreciation of its bearing and intention; and we can safely predict for the benefit of the Council, that its action in this particular will not be the least effectual of its proceedings in hastening its final discomfiture.

It is not without some slight surprise that we find as many as five members of the Council have correctly estimated the determination for reform that exists among the body of the College; but it nevertheless remains that this number voted for further consideration of the resolution providing for annual election of a president by Fellows present at the general meeting. The gentlemen who thus distinguished themselves by dissenting from the illiberal exclusiveness of their fellow Councillors were, Sir Joseph Lister, and Messrs. Heath, Cadge, Holmes, and Erichsen. The proposer and seconder of the opposition motion to ignore the unanimous demand of a representative meeting of their constituents, were Mr. Hulke and Dr. Humphry. It is thus proved, beyond all possibility of doubt, that only five out of the complete Council—omitting the absentee members, Messrs. Holden and Hutchinson, and Sir Erasmus Wilson, resigned—feel any inclination even to listen to suggestions dealing with modifications of their official licence.

The lesson taught by this demonstration will be lasting and salutary, and the extent to which it is destined to influence collegiate affairs in the future will not be long in manifesting itself. Already an extraordinary amount of activity is being displayed in the direction of organising the forces of the reforming party. Committees, local and general, are already in existence in London

and various parts of the country; and a steadily growing feeling of indignation and resentment is displaying itself amongst the many thousands of practitioners whom the Council of the College has chosen to regard with contemptuous indifference.

After playing the part we have already taken in this controversy, we shall not be accused of partiality towards the Council if we suggest excuses for the conduct of some of its members. The youngest in office of these gentlemen can hardly be supposed to have gauged as yet the full extent of their privileges, and doubtless they very considerably magnify the importance of their own influence in shaping the destinies of the corporation to which they belong. For the time they are blinded, probably, by the unaccustomed surroundings of official dignity, and only the more prescient and the less narrow-minded among them can be expected to forego any part of the dominance they find so grateful to themselves. At the same time, too, though it is in the highest degree painful to be driven to the assumption, we are compelled to think that even more senior members of the Council share the weakness of their junior colleagues, while being also, equally with the latter, unable to correctly estimate the signs of the times. Or is it, that being assured of but a brief space of assumed supremacy, they choose to die fighting for official autocracy rather than yield to demands that are directed straight at a limitation of their prerogatives? If the latter, their attitude is even more undignified than that of one struggling for place at the expense of injustice to many thousand others, not less worthy than himself of the position to which his right is freely challenged.

The battle-field between the Council and the College is now an open one; and accordingly as the numerically greater forces combine and order their attack, so will they obtain success more or less quickly. The end, however long it may take to attain, is absolutely certain; and whether the ungenerous attitude of the Council is changed for one of just responsibility to the College this year or next year or the year after, it cannot be deferred for longer than a very brief period of time. That the members of the Council who have declared for place at any price will be replaced, as the period of appeal to popular suffrage comes round, with candidates who possess a finer perception of the rights of the majority is already definitely assured; the pity is that a complete change cannot at once be effected.

THE SHEFFIELD MANSLAUGHTER CASE.

THE case of Mr. Evans who was convicted last week at the Leeds Assizes for the manslaughter of a patient affords a sad example of the effects of intemperance. A woman's life lost; a professional man's prospects blighted; all for the sensuous gratification of that craving for drink which has so often proved the curse of otherwise valuable lives. Having been convicted of the manslaughter of Mrs. Nettleton whom he was attending in her fourteenth confinement, through gross and culpable negligence, the result of intemperance, it was the painful duty of Mr. Justice Hawkins to sentence

him to five months' imprisonment with hard labour. With the sentence and with Mr. Justice Hawkins' manner in passing it no fault can be found. The case was one of cross-birth, with arm presentation. Instead of giving the necessary help himself, or securing proper assistance, he allowed the time to go by when such help would be efficient, giving way whilst waiting to the habit of drinking to such an extent as to render himself incapable. The result was rupture of the womb and death, interference being too late when it did arrive. The sentence would undoubtedly have been a much severer one but for the sensible view taken of Mr. Evans' conduct by the judge. His words are worth quoting. Having expressed the pain he felt in the exercise of his bounden duty, and having recapitulated the facts that formed the grounds for the jury's verdict, he said, "It is a very sad case. I know perfectly well what effect a verdict like that must have upon your professional prospects. It is a most painful thing, I know, for a man of your education to stand in that dock and receive sentence. I know perfectly well the punishment I am about to inflict on you is one which will probably entail great suffering to you during the time you have to endure it. If you had been careless whether the woman lived or died I should have passed a heavy sentence; but I do not believe that was the case. I believe if you had kept your brains free from the influence of drink, in all probability this poor woman's life would have been saved, and she would have been delivered, as she had already been delivered of thirteen children, in safety and by your aid. But you gave way to drink, and in your inflamed condition, I have come to the conclusion that you forgot what was due to the case. You have already been in prison one month. If you had been brought before me immediately after the commission of this offence I should have sentenced you to six months. As it is, taking into consideration the time you have been in prison awaiting your trial, I order you to be imprisoned and kept to hard labour for five months."

Whilst admitting the justice of both the verdict and the sentence, there are a few comments which present themselves to our minds in connection with the case. The first is the question, How was it that the woman's husband permitted Mr. Evans to continue his attendance the moment he became aware that he was at all the worse for drink, especially when he knew that his wife's case was one of considerable danger—so much so that one practitioner who was called in refused to undertake any interference *and went away*, advising further assistance to be obtained. After this opinion had been expressed, the better part of a day was allowed to elapse before help was secured, then too late. In this respect the husband was decidedly guilty of culpable negligence. The second point we would comment upon is the objectionable custom that prevails of pressing medical men when in attendance on midwifery cases to partake of stimulants, too often in such a manner as to make it almost an offence to refuse. In the case before us it is in evidence that Mr. Nettleton supplied Mr. Evans with brandy or whisky with his tea, and we have no doubt that he did so at other times as

well, and that he in great part contributed to Mr. Evans' lamentable condition and its terrible results.

It is a safe rule for medical men to lay down, never when engaged in their professional capacity, to partake of stimulants at their patients' houses, unless they do so at the proper meal times, i.e., luncheon or dinner, and then only in the strictest moderation. The taking of wine or spirits at other than meal times is a practice strictly to be avoided. Some time or other mischief is sure to result therefrom; and one or another may find himself in Mr. Evans' lamentable position, or even worse. The whole affair is an exceeding painful and much to be regretted one.

Notes on Current Topics.

Notification of Infectious Diseases.

WE recently called attention to the fact that the Burghs (Scotland) Bill has been placed on the notice paper, for second reading, of the House of Commons by the Lord Advocate, and that it is due to the blocking of it by the representatives of the "Vigilance Association" that it has not passed. This Bill extends to every considerable town in Scotland the most stringent and oppressive regulations of the compulsory notification code, and places every member of the profession in these towns under a penalty of fine and imprisonment if they omit to report the ailments of their patients to the sanitary authority.

We revert to this subject for the purpose of thanking the "Vigilance Association"—an organisation of anti-vaccinationists, anti-vivisectionists, and anti-Contagious Disease agitators—for having taken the opposition to this most pernicious Bill out of the hands of the Parliamentary Bills Committee of the British Medical Association. This latter department of the Association was, apparently, entirely innocent of the existence of the Lord Advocate's Bill until we called their attention to it, and it had left the medical profession in Brighton to do battle with the notificationists on their own account, not having taken any public means whatsoever to resist the passing of these measures. The journalistic representative of the Parliamentary Bills Committee has, indeed, been kind enough to advise the practitioners of any locality which is threatened with compulsory notification to "take local action," and asks why they have not applied to Sir Charles Dilke for a hearing against the proposal. The answer is simple. It is not the business of the practitioners of a town to take any such step. They pay their subscriptions as members of an Association whose duty it is to protect the medical public against these invasions of their right; that Association has confided to a certain committee, known as the Parliamentary Bills Committee, the fulfilment of this duty, and it is the function of that Committee to take every means possible to carry out the orders given them, and even if the practitioners of the threatened locality made no objection to the imposition of compulsory notification, to resist such imposition with energy and perseverance in the general interest of the profession. Is the Parliamentary Bills Committee waiting for the

medical men of the Scottish burghs to go to Sir Charles Dilke to ask him to speak to the Lord Advocate to get him to withdraw his compulsory notification clauses? If so, we venture to ask, what is the Committee for? and would not the profession in detail do its own Parliamentary work much more vigorously without any "assistance" from it?

Rectal Anæsthesia.

CONSIDERABLE attention is being excited among physicians in America, on the subject of anæsthesia by the rectum, as advocated by M. Mollière. In the *New York Medical Record* a series of cases, in which this mode of anæsthetisation was resorted to, has been recorded by Dr. W. T. Bull, who gives particulars of seventeen instances. The ether is contained in a bottle from which a tube terminating in a vaginal nozzle from a Davidson's syringe passes, and the bottle itself is placed in a reservoir holding water at about 130° F. This temperature suffices to vaporise the anæsthetic, and as it grows too cold for the purpose more hot water is added. In some cases food was withheld from the patients for some hours, and then vomiting did not occur either during or after the administration of ether. It was found by Dr. Bull that, considering the trials as a whole, a much longer time was required to produce insensibility by this method than by inhalation; but the unpleasant effects on the respiratory organs which usually accompany the latter mode, did not occur, or when present created far less irritation in the majority of instances. He reports, however, that seven out of the seventeen patients passed loose motions, sometimes copious and numerous, and in two instances tinged with blood; and he concludes, therefore, that this is a danger which deserves careful consideration in connection with the new mode of etherisation. The principal advantage it appears to possess, is that of permitting the performance of operations on the face without the obstacles which exist when the ordinary method is resorted to. Its drawbacks of discomfort in manipulation, indelicacy, and the demonstrated risk of dangerous injury to the intestine, seem to contra-indicate its use, except under conditions that make it desirable to substitute means of obtaining anæsthesia for that mode now commonly adopted.

Improper Use of the Title Surgeon.

THE Medical Defence Association were last week prosecutors in a case at the Southwark Police Court, where a charge was brought against a person calling himself a surgeon without having complied with the requirements of the law in respect to registration. The defendant had completed the full curriculum of study and had passed the examination in surgery of the Royal College of Surgeons of England, but had not fully qualified by obtaining also a medical licence. He was, however, in practice as a medical man, and described himself on his doorplate as "Surgeon." The magistrate very properly regarded the offence as proven, and fined the defendant £10, with £5 costs. We cannot in any way complain of this result, although it may at first sight appear a somewhat harsh punishment for the offence. The interests alike of the

profession and the public require that every form of unqualified practice shall be repressed; and in this instance, though ostensibly a surgeon, the defendant was still debarred from occupying the legal status conferred by registration, and was thereby, within the meaning of the Act, an unqualified person. The incident serves forcibly to bring out the necessity for such a reform in examinations as the Medical Acts Amendment Bill provides, for under it the partial qualifications conferred by the College of Surgeons will be no longer obtainable; and no candidate will be required to proceed from pillar to post, in other words, from one licensing body to another, in order to secure a registrable title to call himself by any distinctive professional name. We learn that a case for appeal has been granted to the defendant.

An Example for Imitation.

THE laborious and valuable researches of Dr. Koch, the world-famous discoverer of bacillus tuberculosis, have just been recognised by the German Government in a way that must seem strangely out of keeping to our own dispensers of national honours. It will sound almost incredible to English ministers, but nevertheless it is true, that the Reichstag last week decreed that the sum of £6,750 should be distributed among the members of the Cholera Commission of which Koch assumed the command in Egypt and India. Of this sum £5,000 falls to the distinguished chief himself, his followers receiving the balance. Professor Virchow seized the occasion of this vote to enlogise the work of Koch in the highest possible terms, and very deservedly complimented German science on the distinction achieved by his countryman. In addition to this pecuniary reward, Dr. Koch has been further enriched in honour by a nomination to the Crown order of the second class, and by being presented by the Imperial Board of Health with a life-size bust of the Emperor; and all these marks of appreciation and favour to a scientific discoverer! Our rulers may well gaze aghast at such, to them, incomprehensible outpourings to one whose whole effort has been, not to kill as many human beings as possible in the shortest space of time, but to find means of preventing disease, and curing it where present. Such an example may be emulated at home with much advantage; and it may be that this illustration will serve to show in what respect our insular mode of treating great discoverers may be altered.

THE Lords of the Admiralty have awarded the Greenwich Hospital Pension of £50 a year for Fleet and Staff Surgeons to Retired Deputy Inspector-General of Hospitals and Fleets David Lyall, M.D.

A PORTRAIT of Sir Edwin Saunders, F.R.C.S., Dental Surgeon to the Queen, painted by Mr. Macartney, was last week hung on the walls of the Odontological Society's rooms in the Dental Hospital of London, bearing the following inscription: "This portrait of Sir E. Saunders, F.R.C.S., a trustee and benefactor of the Dental Hospital of London, was presented by his friends and colleagues on the occasion of his gift of the Eastern wing of the building in Leicester Square."

Cremation of the late Professor Gross.

THE Nestor of American Surgery has by his death given renewed impetus to the cremation movement, and this by having demonstrated his practical faith in hygienic disposal of dead bodies by leaving directions for his own to be dealt with in the way most agreeable with the dictates of common sense and health. The late Professor had ordered that he should be cremated in the furnace erected at Pennsylvania, where previously the remains of his own wife had been reduced to ashes. The ceremony, therefore, has been duly performed; and thus one more name, and probably the greatest of all, is added to the history of those whose ante-mortem and post-mortem history have both been a protest against that unscientific and unhealthy mode of burial against which the cremationists of this country are vigorously directing their energies.

Paris Academy of Sciences.

THE Academy has awarded, among others, the following prizes for the year 1883:—*Prix Montyon* (Medicine and Surgery) £300, was equally divided among Dr. Constantin Paul, for his work entitled "Diagnosis and Treatment of Diseases of the Heart," Dr. Henr Roger, for his researches on Diseases of the Heart, and Dr. E. Vallin, for his treatise on Disinfectants. The *Prix Bréant*, 5,000 francs, was awarded to Dr. Fauvel, for his researches on the Etiology and Prophylaxy of Cholera. The sum of 10,000 francs was divided among the members of the Pasteur Mission to Egypt, for their devotion to science, and for the important results obtained by them in their investigations during the last epidemic of cholera in Egypt, and at which the much-lamented Thuillier fell a victim. The *Prix Chaussier* was awarded to Dr. Legrand du Sault for his four volumes on Medical Jurisprudence (*Médecine légale*). The *Prix Montyon*, in the section of Physiology, was awarded to Dr. Paul Regnard, for his memoir entitled "*Recherches expérimentales sur les Variations pathologiques des Combustions respiratoires.*"

The Irish Poor-law Inspectorship.

THE appointment vacated by the death of the late Dr. Roughan has been speedily filled by the appointment of Dr. Stewart Woodhouse, of Dublin, Lecturer in the Carmichael College and Assistant-Physician to the House of Industry Hospital. We expressed last week the opinion which we still hold, that a candidate who has served as a Poor-law medical officer has a special qualification for a medical inspectorship which no one else can possess, and that it is both unjust and unwise to appoint to such office anyone outside the Poor-law service. For this reason we regret the appointment of Dr. Woodhouse; but we must do him the justice to say that if it were desirable to go outside the service for an inspector no better choice could be made. Dr. Woodhouse has acted temporarily for the Local Government Board in a tour of inspection in Connaught, and more recently in sundry inquiries under the Labourers' Dwellings Act, and he has shown himself well fitted for the work now entrusted to him.

Furthermore, the appointment has a special claim upon our approval, inasmuch as it was entirely non-political and—so far as we know—uninfluenced by party or religious bias, and dictated only by a sense of Dr. Woodhouse's fitness for the office.

Port of London Sanitary Authority.

We are informed by the Medical Officer for the Port of London that by a recent warrant of the Treasury the limits of the Port of London have been greatly extended. Commencing above at Teddington Lock, they extend down both sides of the river Thames to an imaginary line drawn from Havengore Creek on the north side to the land's end at Warde Point in the isle of Sheppey on the south side, including both sides of the Medway as far as a line drawn—Colemouth Creek to Stangate Creek, from there to Swale Church, and from thence to Elmley Chapel in the isle of Sheppey, with all streams, docks, basins, creeks, islands, &c. The result of this warrant is to place under the jurisdiction of the Port Sanitary Committee of the Corporation of London an additional district of from 20 to 30 miles in length, and including the important ports of Sheerness, Queenborough, and Port Victoria.

Gynæcology and Socialism.

THE limits of our belief in the naughtiness and vagaries of gynæcology in unscrupulous and ignorant hands are not narrow. But, what will the distinguished and talented author of the Gulstonian Lectures for 1884 say to the following, which we quote from the *London Medical Record* for May 15th, 1884? "It is time (says Dr. Allbutt) that we complete our reaction from this gynæcological tyranny, and that we, of this College, no longer permit ourselves to be snubbed by these brethren of ours, who calmly tell us with their superior airs, that our use of such expressions as uterine neuralgia, irritable uterus, ovarian neuralgia, neurasthenia, and the like comes of a shallow *Socialism*, and is grounded upon the emptiness of our knowledge of uterine diagnosis"! This is really too much, and, as even the worm will turn, we general physicians would do well to resent with all our might any such shocking charge.

Death of M. Wurtz.

THE illustrious French chemist, M. Wurtz, died on Monday, the 12th inst., at his residence in Paris, the event having been sudden and quite unexpected. The deceased was 67 years of age, and was well known in every country where science is cultivated and understood. As Professor of Medical Chemistry in the Medical Faculty of Paris, he succeeded to the late Jean Baptiste Dumas, who predeceased him by but a few weeks; in 1865 he was elected Dean of the Faculty of Medicine, a position he continued to hold until his resignation of the post in 1875. On the Atomic Theory of Chemistry he was a well-known author, his work on this subject having been published in English in the "International Scientific Series." Wurtz was a Commander of the Legion of Honour, and a Life Senator, and in 1865 he obtained the Biennial prize of £20,000.

Lecture Arrangements at the Royal College of Surgeons, England.

THE lectures at this College for the present year will be resumed on Wednesday, the 4th of June next, by Mr. Albert Schafer, F.R.S., who will deliver on that day and on the 6th and 9th of June, three lectures on "Physiology." 1. "The Functions of the Marginal Convolution;" 2. "The Analysis of Voluntary Muscular Action;" and 3. "The Mechanism of Absorption." Sir Henry Thompson, F.R.S., will conclude the course for the present year by delivering, on the 11th, 13th, 16th, 18th, 20th, and 23rd of June six lectures on "Some Important Points in connection with the Surgery of the Urinary Organs."

An Undignified Coroner.

IN the Queen's Bench Division, before the Lord Chief Justice, a case was heard on Friday last arising out of a charge of libel preferred against the *Kentish Observer* newspaper by Dr. T. S. Johnson, Coroner for Canterbury city. The libel complained of accused Dr. Johnson of having behaved in an undignified manner on several occasions while presiding in his own court, and according to the published evidence adduced before the Lord Chief Justice, it would seem that the accusations were not altogether unfounded. Dr. Johnson does not appear to have entertained any very clear ideas respecting the importance of his office, nor of the demeanour which ought to characterise a coroner in his official capacity. For instance, an old woman who attended before him as a witness at a certain inquiry, and who suffered from rheumatism, was advised by the Coroner to "go to the 'Grand Old Man' at Cannes," and the Lord Chief Justice very properly demanded by what right the plaintiff, as a judge, presumed to speak in this manner of the Prime Minister of England. His Lordship further asserted his intention of laying the conduct of the Coroner before his superiors, and he also observed that full shorthand notes of the case should be taken. The action was adjourned till Monday, and eventually resulted in a verdict in favour of Dr. Johnson, with £100 damages. Whilst congratulating plaintiff on having gained the verdict of the jury, it is impossible to feel anything other than regret that a member of the medical profession should have conducted himself in such a manner while fulfilling the important and onerous duties attaching to the coronership of a large city as to call forth the unfavourable comments of the Lord Chief Justice.

The Health of the Country.

It appears from the quarterly return of the Registrar-General, just issued, that during the three months ending March 31st last, 285,545 births and 175,361 deaths occurred in the United Kingdom, the total population being estimated at 35,951,865 persons. The English death-rate for the quarter fell to 3·7 below the mean rate for the ten corresponding quarters previously, and was lower than the rate recorded in any winter quarter since civil registration commenced. The deaths from zymotic diseases amounted to a total of 13,552, scarlet fever being credited with the largest proportion, viz., 3,265. Small-pox carried off 315

a larger number than has been registered in any quarter since the second of 1882; sixty of these fatal cases occurred in "Registration London." 5,141 deaths were uncertified; and it is stated that in Wales 10·2 per cent. of deaths are unregistered.

The Health Exhibition.

THE Exhibition Committee may now be safely congratulated on the assured success of the monster collection brought together at South Kensington under their auspices, for during last week more than sixty-seven thousand visitors were admitted to the courts. Though still by no means complete, the Exhibition nevertheless contains very much more than can be examined by even the most cursory sightseer during a single visit; and when the whole arrangements are perfected, which it is hoped will have resulted in about a fortnight, it will be still more deserving of the favour that is being shown to it. That such a display is capable of imparting scientific knowledge and healthful instruction cannot be doubted, and we hope as time progresses to draw lessons therefrom which shall interest our readers and afford hints for those who may be unable to visit the Exhibition themselves.

THE annual dinner of the Army Medical Department will be held at the Holborn Restaurant on Friday, 30th May.

AMONGST the fifteen gentlemen recommended by the Council of the Royal Society for election to the Fellowship are the following:—Professors J. G. Allman, Isaac Bayley Balfour, J. G. McKendrick, C. S. Roy, and Dr. A. Ransome.

WE understand that Sir Spencer Wells, Bart., F.R.C.S., has received the decoration of Commander of the Royal Norwegian Order of St. Olaf, forwarded by direction of his Majesty the King of Sweden and Norway.

MRS. GOODING, the wife of Dr. J. Callender Gooding, of Cheltenham, committed suicide on Friday last in her bathroom by stabbing herself to the heart with a surgical instrument belonging to her husband. The deceased is stated to have been lately mentally depressed.

AT the last meeting of the Harveian Society of London a vote of condolence was unanimously passed to the President, Mr. Geo. P. Field, on the death of his father, Mr. Octavius A. Field, F.R.C.S., which had occurred since the previous meeting of the Society, of which deceased was its oldest member and Vice-President.

THE third general meeting of the Hospitals Association will be held at No. 11 Chandos Street, Cavendish Square, W., on Wednesday, the 21st May (to day), 1884, at 8 p.m., when Mr. Henry C. Burdett will read a paper entitled "How can the Hospital Sunday and Saturday Funds be made more useful to the Hospitals?"

THE Local Government Board has approved of the purchase by the Metropolitan Asylums Board of the river steamer *Albert Victor*, at a cost of £3,000, to be used as an auxiliary to the hospital ships now stationed in the Lower Thames. Its purchase has become necessary in consequence of the present tendency to an increase of small-pox in the metropolis.

A LUNATIC named Hale, who escaped from the Dumfries Asylum recently, died shortly after his recapture, and an examination showed that several ribs were broken. On the case being reported to the authorities, the arrest of the keepers who had recaptured the man was ordered, but it was found that in the meantime one of them had committed suicide and the other had escaped.

AT a meeting of the Governors of the Apothecaries' Hall of Ireland, held on the 9th inst., the licence was conferred, *honoris causa*, on Professor Rawdon Macnamara, of Dublin, "in consideration of his high scientific and professional attainments, and especially for his valuable contributions to materia medica and pharmacy." It is stated that this is only the second occasion on which the licence of this corporation has been so bestowed.

IN the principal foreign cities the rates of mortality per 1,000 of the various populations were, according to the latest official returns, as follow:—Bombay 27, Paris 26, Geneva 36, Brussels 25, Amsterdam 29, Rotterdam 35, The Hague 26, Copenhagen 20, Stockholm 26, Christiania 19, St. Petersburg 47, Berlin 24, Hamburg 26, Dresden 23, Breslau 27, Munich 32, Vienna 32, Prague 36, Trieste 32, Turin 32, Venice 25, New York 24, Brooklyn 18, Philadelphia 24, and Baltimore 18.

THE deaths registered last week in the principal large towns of the United Kingdom corresponded to an annual rate of 21·8 per 1,000 of their aggregate population. The death-rates in the several towns were:—Brighton, Derby 14; Hull 16; Norwich 17; Bristol 18; Salford 19; Sheffield, London, Huddersfield 20; Sunderland, Birmingham 21; Bolton, Newcastle-on-Tyne, Cardiff, Bradford, Oldham 22; Halifax, Wolverhampton, Birkenhead, Edinburgh, Leicester 23; Portsmouth, 24; Leeds, Nottingham 25; Manchester, Preston, Liverpool 27; Plymouth, Blackburn, Glasgow 28; Dublin 31.

THE highest annual death-rates last week in the large towns from diseases of the zymotic class were—From measles, 5·5 in Oldham, 3·1 in Portsmouth, 2·1 in Plymouth, and 2·0 in Nottingham; from whooping-cough, 2·6 in Liverpool, 2·4 in Bolton, and 1·5 in London; from scarlet fever, 1·9 in Leeds, and 1·7 in Sheffield; and from "fever," 2·0 in Portsmouth, and 1·4 in Blackburn. The 20 deaths from diphtheria included 7 in London, 5 in Glasgow, 2 in Edinburgh, and 2 in Cardiff. Small-pox caused 19 deaths in London, 2 in Liverpool, and 1 in Sunderland.

Scotland.

[FROM OUR NORTHERN CORRESPONDENTS.]

ABERDEEN ROYAL INFIRMARY.—The annual report of the managers of the Aberdeen Royal Infirmary states that during the past year nearly 2,000 persons were received into the wards, and that 1,800 received advice and medicine as out-door patients. The managers make an urgent appeal to the public for funds, the financial state of the hospital being again viewed with deep concern. The total income for the past twelve months was £3,951, and the expenditure £7,611. An extension of the hospital buildings, to cost from £8,000 to £10,000, is in contemplation, towards the cost of which the sum of £3,118 has been collected.

UNIVERSITY OF EDINBURGH—FACULTY OF MEDICINE.—The Vans Dunlop Scholarship in Physiology and Surgery has been awarded to Mr. Joseph E. Bowser.

MEASLES IN JEDBURGH.—In consequence of the prevalence of measles in Jedburgh, it has been deemed advisable to close the Grammar School, and it is likely that the same precaution will be adopted in regard to the other educational institutions.

THE ROYAL COLLEGE OF SURGEONS OF EDINBURGH.—Owing to a recent decision of the College creating the post of Vice-President, Professor Turner, as the last President, was elected Vice-President during the term of office of the present President.

THE HEALTH OF EDINBURGH fluctuates but little if we take as a basis the reports of the Medical Officer of Health, and on the whole it will compare very favourably with any other city of equal size. This was shown very plainly in the monthly report submitted to the Public Health Committee last week, which gives an average death-rate for the last five years of between 20 and 21 per 1,000 of its population, with scarcely any variation of the deaths during the month referred to. 126 were registered in the New Town, 241 in the Old Town, and 59 in the southern suburbs; and in respect of age, 158 were registered as under 5 years, 174 as between 5 and 60 years, and 94 above 60 years. Deaths from diseases of the chest amounted to 156, or 36·61 per cent. of the whole; while 39 deaths, or 9·15 per cent., were due to debility and old age. Diseases of a zymotic nature proved fatal in 61 cases (14·31 per cent. of the total mortality), and were made up as follows:—Typhus 2; typhoid fever 1; diphtheria 4; scarlatina 5; measles 9; whooping-cough 38; and erysipelas 2. The births registered amounted to 655 (364 males and 291 females), giving a rate of 31·86 per 1,000 of the estimated population. The illegitimate births numbered 46. During the month 391 cases of infectious diseases were intimated, as provided by the Municipal and Police Act—these consisting of 231 of measles, 95 of scarlatina, 44 of typhoid fever, 18 of diphtheria, 3 of typhus fever, and 1 of small-pox.

GLASGOW DEATH-RATE.—The death-rate of Glasgow for the week ending with Saturday, the 10th inst., was at the rate of 29 per 1,000 per annum, as compared with 27 in the previous week, and 31 in the corresponding week of last year.

The Victoria Institute.—A meeting of this institute took place on Monday evening, when a paper on "Evolution by Natural Selection" was read by Dr. J. Hassell, after which a paper on "The Glacial Epoch," by Mr. Macintosh, F.G.S., was read and discussed. Mr. Charlesworth exhibited a rare specimen of a mastodon tooth, recently found in South America.

Correspondence.

WHAT IS MEDICAL ADVERTISING?

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—I have read with much thoughtful interest the letter in your columns on the above subject signed "Anti-Humburg," who evidently approaches his subject in a catholic spirit. What is "legitimate" advertising? What is "illegitimate" advertising?

To me it appears "legitimate" advertising consists in advertisements in medical papers; advertisements in lists of Hospital Reports; in lists which appear in the Directory; and at least go to the lay governors of hospitals; in delivering sundry lectures before the College of Physicians (the lecturers being chosen by no known rule); and in appearing in the public press when any peer, or still more, any member of the Royal Family, has sneezed unduly, or a diplomatist has had some dropsey in his lower extremities.

Then "illegitimate" advertising consists in advertisements in lay papers—the works of men eminent in the Royal College of Physicians figuring conspicuously in this impropriety; writing a book which is lucid enough to be understood by an intelligent layman who wants to know something about the malady under which he is, or is told, or believes himself to be labouring.

This is a most wicked form of advertising—in the eyes of those who do not, probably because they can not write a lucid book. If it is any consolation for these inept critics, they may make themselves quite easy with this fact, that if a man writes a useful book, nine-tenths of the medical readers of it will continue to take the whole of their paying patients to their private friends, or to the consultants who "dine" them. As long as curiosity survives in the human breast, so long will certain persons persist in knowing what is written on the maladies concerning themselves in treatises addressed to the profession; and whenever such a treatise is written in fairly readable English, so often will the grudging, carping critic decide that it is "written for the public." The cup of his wrath brims over when a patient has got to know something more on any medical subject than he himself knows, and when talked to on the subject his ignorance is patent. That is "illegitimate" advertising with a vengeance! The medical man does not exist for the benefit of the patient; the patient exists for the benefit of the medical man: that is the creed of many. Can it be denied that many men take their patients to consultants, not because they are the best men for the patients, but because it is to the interest of the family practitioners to take them to sundry men? And perhaps some of the patients can detect the little arrangement. How many books have been announced as "preparing for the press" that have never seen the printer; but which have paid the professing author well by connecting his name with some special subject on which he wishes to be thought an authority? The red lamp, the brass doorplate, are these solely "mounted" to guide bewildered messengers to the right door?

There are various ways of being brought before the public; there are various ways of procuring an income. A man becomes attached to a teaching hospital where the surgeon calls in his colleague the physician when another opinion is needed; then they feel the obstetrician should be consulted; then the eyes ought to be examined, and their colleague the oculist is brought on the scene; and so on, and so on, until the pathologist is required; and the "school" can furnish that too. To be one of such a pack, who hunt together, is no doubt a very nice thing for the man who can manage it. Nor is it unknown that certain men of position "dine" the general practitioners who call them in, whether the best men for the patients or not. Is it worse for a man to advertise in lay papers? Is there anything more harmful to the interest of patients in doing this than in either of the two ways of "making practice" just spoken of? Suppose the writer cannot do the first, and does not feel inclined to adopt the latter plan!

The "unwritten laws" of the College are a simple farce, by which those in power can stab at a man whom they do not like; just as their selections are capricious in favour of those they do like. Considering the actual facts of the case, the sooner the old lady in Pall Mall tears up her "unwritten laws" the better. Had we not better get rid of our Phariseism and come out in our true colours, as "Anti-Humburg" suggests?

The way of getting on which suits a man is (or ought to be) legitimate; the way which is likely to avail a rival is (or ought to be) illegitimate. That is about the figure of it. That is our creed and our practice! And so long as the profession tolerates the sham (specially of the College of Physicians guaranteeing the conduct of its Fellows and Members—to each other)—the hollow pretexts which cover sordid motives—the peculiar arrangements which advantage one man to the exclusion of others—so long will it hold the position accorded to it, which is certainly no lofty one,—though perhaps as good as it deserves. As soon as the profession becomes honest and true to itself it will be honoured and respected accordingly by those outside it. A man wants to get on in the world; the first thing to be done is to make the world aware of his existence; the next to keep it from forgetting the fact. One man does this one way; another man another way. Every effort is an advertisement in reality; but one has the sanction of precedent, and therefore is proper: the other has not, and ought to be condemned. To advertise is “to make known,” no matter by what means.

I am, &c.,
PARACELSUS.

WHAT IS A MEDICAL ADVERTISEMENT?

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—As you have opened your columns to a discussion of this burning question, which affects more or less every member of the profession, and as your correspondent “Anti-Humbug” pertinently asks, “What is a medical advertisement?” I will give him my idea of one most objectionable form of it. Last week there appeared the following announcement in all the London daily papers:—“We are asked to state that Baker Pacha, who is staying at Mackellar’s Hotel in Dover Street will to-day undergo an operation by Sir W. MacCormac.” Now who asked the papers to state this? If Sir Wm. MacCormac, then, according to my opinion, that gentleman has been guilty of issuing a medical advertisement which is simply indefensible. Baker Pacha is not such a lustrous star that the world need be told that he is to have a splinter removed from his cheek any more than any other soldier or civilian; nor need the world be enlightened with the knowledge that Sir Wm. MacCormac has been specially retained for this marvellous operation, except for the advertisement such an announcement gives to this gentleman. Following this, two or three days later, your contemporary the *Lancet* (the first to attack small fry, and the first to toady to and to puff the favoured few) describes the operation by Sir Wm. MacCormac, states that it was somewhat prolonged, and then sends round the paragraph to the daily papers for quotation. Again, who sent this information to the *Lancet*, and for what purpose, if not with the object of getting a gratuitous advertisement in the newspapers?

If the Colleges were to look a little more after their heads, than be continually framing rules for the guidance of that large body of men who look upon these newspaper puffs with contempt, they would the better serve the profession, and more effectually stop that indirect advertising which all right-minded members must deplore.

I am, Sir, yours, &c.,
A FELLOW.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—I have read with pleasure the able letter from “Anti-Humbug” in your last issue on the above subject. In answer to his request that we should call a spade a spade, I send the following cut from the *Edinburgh Courant* of one day last week:—

INTERESTING TO GENTLEMEN.

I, DR. DANIEL SUTHERLAND, Surgeon at the New Medical Hall, 73 Jamaica Street, Glasgow, hereby intimate to all whom it may concern, that I have long studied and treated Confidential Complaints and Weaknesses as a principal part of my Practice, both here and in Edinburgh, though never formerly made known by Advertisement, and it is possible this notice may be construed as a breach of professional etiquette; but I think it very pardonable when I consider the number of gentlemen constantly consulting me

with their Constitutions injured, and Complaints aggravated, after being for months or years the dupes of Quacks and Druggists. I consider it a righteous necessity in the Public interest to advertise the fact that a Member of the Profession proper devotes his time to the study and treatment of these special Complaints. Gentlemen are therefore inexcusable if they fall into the hands of empirical pretenders. I make free to assure Gentlemen entrusting me with their confidence that they may rely upon the highest professional honour and skilled conscientious treatment, whether they visit me at 73 Jamaica Street, Glasgow, or communicate with me by letter, which will have my immediate attention.

I am, faithfully, DANIEL SUTHERLAND,
Licentiate of the Royal College of Physicians, Licentiate of the Royal College of Surgeons; also of the Faculty of Physicians and Surgeons. For seven years Councillor and Trustee of the City of Edinburgh, and Manager of the Royal Maternity Hospital, Edinburgh; President of the Scottish Christians’ Evidence Society; Medalist (Royal College Surgeons) 1867; awarded Queen’s Prize (Science of Chemistry) Kensington Museum, 1868; Public Honour (Royal College of Surgeons), 1869, &c.

Now, Sir, I beg to say that I admire Mr. Sutherland; he comes to the point at once. I admire him far more than his miserable imitator who becomes an Elder in a Free Kirk in Scotland, or a Deacon in an Iron Tabernacle in England. It must be noticed, also, that Mr. Sutherland acts from the feeling of righteous necessity, and that he is the President of the Scottish Christians’ Evidence Society. I have not the slightest doubt, Sir, that if Mr. Sutherland makes a good fortune from his advertisement, which I hear that he is in a fair way of doing, and if he will only bring over from the City of the Montezuma’s some old idol for the Calton Hill, Edinburgh, or the Thames Embankment, and give some good dinners, he will be received into the bosom of a loving profession. Anyone who reads the above advertisement cannot but fail to perceive that Mr. Sutherland has taken a true measure of his countrymen: the happy blending of the commercial with the pious spirit of the country is delightful. His modest desire to be of service to suffering humanity, mixed with the evidences of Christianity, is at once a compliment to the sagacity of the man as to the simplicity of his countrymen. Cant, cant, is what the people want, and cant they shall have, and when I have made money my professional brothers who attack me will forget the past in a good dinner. Mr. Sutherland’s advertisement is to me exquisite.

I am, &c.,
A THOROUGH HUMBUG.

PECULIAR CASE OF DIURNAL THIRST.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—A near relation of my own, of the female sex, about sixty years of age, has been complaining for the last six months with chronic bronchitis. She did not apply for medical advice until lately, and under treatment the bronchitis has almost completely disappeared. She is greatly troubled with an insatiable thirst, which begins after breakfast-time (8 o’clock), and continues until evening, when it takes its departure, to be followed on the next day by its arrival at the same time and so on *de die in diem*. With the thirst comes on very great debility, so that she is unable to do anything except sit and drink; every turning over the leaves of a book is a burden to her. When the thirst departs the great debility goes with it, and she is able to go about her household duties. She generally sleeps soundly at night, and when she awakes in the morning resolves to do a good many things through the day, but is disappointed by the thirst and weakness coming on after breakfast and continuing until evening. I would feel extremely grateful if you or any of your readers could recommend anything that would remove the insatiable thirst and accompanying debility.

Yours, &c.,
G. W. T.

[Our correspondent has omitted to make mention of the condition of his patient’s urinary and cardiac functions. A knowledge of these would assist diagnosis.—ED.]

Literature.

VOICE, SONG, AND SPEECH. (a)

THE volume before us is not so much addressed to medical readers as to the public generally, and more especially to those whose profession or vocation necessitates a frequent use of the voice, either for speaking in public or in singing. It has a dual authorship, Mr. Lennox Browne and Mr. Emil Behnke. Both authors are well qualified to write such a work, the one from the point of view of a specialist on throat affections, the other as a well-known teacher of vocal physiology and the theory of music. Mr. Emil Behnke's little work on "The Mechanism of the Human Voice" is one of the best books for its size, on the subject, that we are acquainted with; and, in the volume before us, he has increased his reputation as an exponent of the physiological and hygienic laws that influence the production and cultivation of the voice. Mr. Lennox Browne has brought his artistic skill and manipulative dexterity to bear in the production of the laryngoscopic photographs illustrating the various registers. These photographs, though we cannot admit that they add anything to our knowledge, are unique of their kind, and at least invest their subject with a certain degree of interest for those who are ignorant of the use of the laryngoscope. The subject is rightly entered on by a rapid survey of some of the simpler forms of musical instruments, and in a simple and popular fashion the anatomy of the human larynx is discussed. The authors adopt the view that the human voice can not be said to have an exact analogy to any form of musical instrument, "it is in its entire no more a reed instrument than a flute, pipe, or a string instrument." The speculative ideas regarding the influence of configuration, and type of body, on the voice are noticed. All we appear at present to be certain of, is the relation here shown between the length and consistence of the vocal ligament, and the pitch and tone. This is, of course, only what we should expect. With regard to the statement, that the presence of the laryngoscopic mirror does not prevent the production of pure vocal tones, we should have thought it superfluous to refer to the fact. Every laryngologist is in the habit of testing the qualities and tone of a singer's voice when recovering from any partial paralytic or congested state. We are cognisant of some distinguished amateurs who rather enjoy this testing of their voices, and the singing of the scale when the laryngoscopic mirror is applied. There is no more important portion of the work than that which has reference to the early training of the musical ear. The eminently practical caution "to avoid the piano and harmonium" and to train by means of the violin or voice, we hope will not be lost on those parents and teachers who read the work. There is one good result which we may hope will be achieved through popularising the knowledge of laryngoscopy. The better understanding of the use of the instrument may help to relieve the public mind of the ignorant ideas with which its application is regarded. We have had far too much of necromancy in this specialty. The laryngoscope opened the door for a vast amount of charlatanism. To magnify the snipping off of a uvula or the removal of a tonsil with a guillotine, into a formidable operation; to impress a patient with a serious sense of the difficulty of touching the vocal cords with a laryngeal brush and a little chloride of zinc, or imbue him with the notion that there is something formidable in the insufflation of a microscopic powder, or to continue these touchings and blowings, *ad infinitum*, has not elevated the science of laryngology. It is full time that the public should come to regard the laryngoscope as one of the simplest of appliances, that most men and women can use for themselves, and to see that the majority of throat affections are such as any practitioner of average intelligence can successfully treat. If for no other reason than this, we are rather glad that this book has been given to the public. The chapters on "Voice Cultivation" and the daily life and "ailments" of the "voice user" are replete with useful information plainly and popularly told. There is an admirable chapter on "Stammering" and "Stuttering," and the differentiation of these vocal defects is concisely given in a tabular form. We

regret to have to make exception to one feature of this work. Evidently the authors themselves recognised the grave irregularity, to use a mild term, of introducing under their supervision a collection of trade advertisements, for they think it necessary to preface this advertisement section by a sort of apology for their insertion. We should be sorry to find this plan of cutting down the expense of the publication of a work generally adopted, or to think that medical authors should either directly or indirectly mix themselves up with a series of pure trade announcements. This plan is the more to be condemned, as several of the advertisements contain allusion to one of the authors or extracts from his writings. We are compelled to make this comment, and feel confident that most medical writers will endorse our criticism of the practice. How far also it is in good taste, or in accordance with professional custom to introduce into a popular work and other pamphlets, excerpts of reviews of purely medical writings, we leave it to the authors themselves to say. As a useful popular book for those interested in song and speech, this work can hardly be surpassed. The illustrations are well executed, and the volume itself both in type, paper, and finish, reflects the greatest credit on the publishers.

Medical News.

King and Queen's College of Physicians.—At the May examinations the following candidates obtained the licences in Medicine and Midwifery of the College:—

Medicine.

Barnes, Ernest Wickham

O'Gorman, P.

Society for Relief of Widows and Orphans of Medical Men.—The annual general meeting of this Society was held on Tuesday, 13th inst., Sir James Paget, Bart., President, in the chair. From the report read and adopted it appeared that the members of the Society number 370, the same as in the previous year; eleven new members had been elected during the year, six had died, and five resigned. Fifty-seven widows and five orphans were in receipt of grants, 3 widows less than in 1882; no fresh applications for assistance had been made during the year. A sum of £2,776 had been distributed, and the expenses of the year amounted to £226. The receipts available for payment of grants and expenses had been £3,160. Two legacies had been paid, which, with a life subscription of 80 guineas, had been added to the funded property, making an increase of £311 10s. to the amount standing in the names of the trustees. Mr. James T. Ware and Sir Erasmus Wilson were elected Vice-Presidents, in the place of Sir James Paget, elected President on the retirement from office of Sir George Burrows, and Mr. Charles Hawkins, resigned. Dr. Kempster, Mr. Felce, Mr. Brodhurst, Mr. B. J. Lowne, Dr. Herbert Davies, and Dr. Russell Reynolds, were elected Directors in the place of the six senior who retired by rotation. A grant of £15 was made under a special by-law to the daughter of a deceased member. The chairman, Sir James Paget, in moving a vote of thanks to the editors of the medical journals, was pleased to have the opportunity of expressing how much the Society was indebted to the editors for the kindness and readiness they had always shown in forwarding and making known to the medical profession the great benefits the Society was able to confer on the widows and orphans of deceased members. After the usual complimentary votes the meeting separated.

Notices to Correspondents.

55 CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a distinctive signature or initials, and

(a) "Voice, Song, and Speech." By Lennox Browne, F.R.C.S. Ed., and Emil Behnke. Pp. 322, London: Sampson Low, Marston, Searle, and Livingston. 1883.

avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

LOCAL REPORTS AND NEWS.—Correspondents desirous of drawing attention to these are requested kindly to mark the newspapers when sending them to the Editor.

READING CASES.—Cloth board cases, gilt-lettered, containing 26 strings for holding each volume of the *Medical Press and Review*, may now be had at either office of this Journal, price 2s. 6d. These cases will be found very useful to keep each weekly number intact, clean, and flat after it has passed through the post.

AN AMATEUR AUTHOR.—The populations of the cities referred to in your inquiry are given respectively by the Registrar-General thus: London, 4,019,361; Paris, 2,239,923; New York, 1,333,851; Berlin, 1,236,092. The next most populous cities are: in America, Philadelphia, 927,520; in Europe, Vienna, 759,849.

A PUZZLED STUDENT.—The word is used in two senses; derived from the Greek (*apnea*, I breathe not), it is generally used to express a condition in which, owing to an abnormally large supply of oxygen to the blood, the respiratory movements are temporarily suspended. It is sometimes used pathologically as the exact opposite of this, almost synonymous with a *phylax*.

UNGT. SULPH. CO.

To the Editor of the MEDICAL PRESS AND CIRCULAR.

SIR—Dr. Hannah is quite wrong in asserting that "Trooper's ointment" is a common name for ung. hydrargyri. Its common name in relation to pedicul is "blue butter." I reiterate that the essential composition of "Trooper's ointment" is sulphur flour, rendered more active by soft soap, the irritation of which latter is soothed by mallow. A little mercurial ointment is frequently added for the benefit of the "crabs," from which recruits are seldom free; and, in the presence of the soft soap, it is instantly effectual.

Yours, &c.,

CONTRIBUTOR.

DR. C. JONES.—The particulars of the case were fully reported at the time of its occurrence. Little good would be done by recapitulating all the details at this stage of the history.

ROXBURGH.—We are informed that the conjoint scheme of examination agreed upon between the Scotch medical licensing corporations will come into operation on October 1st next, and that it will remain in force for a period of five years; presuming, of course, that legislation does not destroy the effect of the conjunction.

MR. CARNEGIE.—On such a question it is quite impossible that you can obtain an opinion which will carry greater weight than that of the gentleman you have named. It may be at once taken for granted that whatever he considers to be necessary is the only essential to success.

MR. CHILD.—Small-pox is very prevalent in Hackney and other parts of East London at the present time. We are unable to confirm your statement as to the other quarters of the metropolis named by you.

CHLOROS.—There is no reason to regard the preparation as anything superior to the ordinary run of quack remedies. It is also quite usual for those who employ such nostrums to relapse into a state infinitely worse than that they were in before resorting to them. This is probably a compensation insisted on by Nature, on account of the outrage done to law and common sense by the employment of supposed curative agencies the composition of which is entirely unknown to all but the maker.

ON THE USE OF TANNIN IN NASAL POLYPI.

To the Editor of the MEDICAL PRESS AND CIRCULAR.

SIR—At page 461 of your issue of the 14th May, I see a note from Dr. Neale, very properly claiming for Mr. T. Bryant priority to Dr. Bell in suggesting and practising the use of tannin for nasal polypi. Mr. Bryant having used it in 1847, as shown in the "Medical Digest," I would beg space to state that the treatment by tannin snuff (either alone or combined with dried alum) is one of the modes I have adopted for many years, having been taught it before 1860 by my old master, the late Dr. Harward O'Farrell, of Boyle, co. Roscommon, a man as distinguished for his modesty and retiring disposition as for his extensive professional knowledge, transcendent ability, and successful practice, being as an "all round man" certainly not inferior to any one I have ever met. I think it is due to the memory of my old master that I should claim any credit that may be due to priority in the use of tannin and other astringents in the treatment of nasal polypi.

Yours, &c.,

J. W. WYBRANTS OLIPHANTS,
Medical Officer, Downpatrick District.

The Villa, Downpatrick,
May 15, 1884.

DR. ALBERT (Paris).—We should consider the insertion of such an announcement an insult to our readers, and are surprised at your sending it.

DR. D. C. B. (Glasgow).—We will make inquiries as to the authorship of the anonymous work in question, and let you know the result.

MR. E. T. S.—The opinion of our contemporary is perfectly justified. Sorry we cannot take your view of the case.

A SENSITIVE M.D. is thanked for his suggestive letter. The matter shall be considered, and the result communicated. The assurance of disinterestedness is quite unnecessary from the tone of his letter, and the object a decidedly deserving one.

Meetings of the Societies.

WEDNESDAY, MAY 21ST.

HOSPITALS ASSOCIATION.—The third general meeting will be held at 11 Chandos Street, Cavendish Square, W. Paper by Mr. Henry C. Burdett, on the question, "How can the Hospital Sunday and Saturday Funds be made more useful to the Hospitals?"

FRIDAY, MAY 22ND.

CLINICAL SOCIETY OF LONDON.—At 8.30 p.m., Mr. William Anderson, A Case of Pyelo-lithotomy.—Dr. Finlay, Sequel to a Case of Aortic Aneurism.—Mr. Golding-Bird, Two Cases of "Hernie en bissac."—Dr. F. Taylor, A Case of Impaction of Bone in the Larynx.—Mr. B. Roth, Living Specimen—Uncommon Lateral Curvature of Spine, with extreme osseous deformity.

SATURDAY, MAY 24TH

ROYAL INSTITUTION.—At 8 p.m., Professor Bonney, Microscopical Geology.

Vacancies.

Ballina Union, Ballina Dispensary.—Temporary Medical Officer. Salary, 3 guineas per week. Election, May 22.
Birmingham and Midland Free Hospital for Children.—Acting Physician. Applications to the Medical Committee by June 4.
Glamorgan and Monmouthshire Infirmary and Dispensary, Cardiff.—House Surgeon. Salary £100, with board, &c. Applications to the Committee by May 31.
Owens College, Manchester.—Assistant Lecturer in Medical Jurisprudence and Demonstrator in Practical Toxicology. Applications to the Registrar by May 21.
Sunderland Infirmary.—A Senior House Surgeon. Salary, £100, with board and residence. Applications to the Chairman of the Medical Board by June 2.
The General Hospital, Birmingham.—Resident Assistant Surgical Officer. Salary, £70, with board and residence. Applications to the House Governor by May 31.

Appointments.

ALLEN, W. H., M.B. Dub., L.R.C.S.I., Medical Officer for the Sixth District of the Lincoln Union.
CAMPBELL, A., M.B., C.M. Glas., Medical Officer for the Workhouse, Bingham Union.
DUNCAN, W. A., M.D. Brux., M.R.C.P.L., Assistant Obstetric Physician to the Middlesex Hospital.
ERSKINE, J., M.A., M.B., C.M., L.F.P.S. Glas., Surgeon to the Ear Department of Anderson's College Dispensary, Glasgow.
GILBERT, H., M.R.C.S., Medical Officer for the Fifth District of the Wolverhampton Union.
GOSLING, J. H., M.R.C.S., House Surgeon to the Morpeth Dispensary.
GREVES, E. H., M.B., C.M. Ed., Physician to the Children's Infirmary, Myrtle Street, Liverpool.
HUGGARD, W. R., M.D. Q.U.I., M.R.C.P. Lond., Assistant Physician to the West End Hospital for Diseases of the Nervous System, Paralysis and Epilepsy.
LOTHIAN, J. A., M.D., F.F.P.S. Glas., Surgeon to the Glasgow Royal Infirmary.
MCDONNELL, C., L.R.C.S.I., Surgeon to the Dawson Street Dispensary, Manchester.
NUNNERY, R. J., L.R.C.P. Lond., M.R.C.S., Junior House Surgeon to the Macclesfield General Infirmary.
PUGH, R. N., M.B. Lond., F.R.C.S. Eng., Surgeon to the Children's Infirmary, Myrtle Street, Liverpool.

Births.

BARKER.—May 13, at 87 Harley Street, London, W., the wife of Arthur E. Barker, F.R.C.S.I. & E. of a daughter.
BOSWELL.—May 13, at Ashburn, Derbyshire, the wife of Alex. Boswell, M.D., of a son.
BROWN.—May 17, at Sowerby Bridge, Yorks, the wife of W. Perrin Brown, L.R.C.P., of a daughter.

Marriages.

CRAIGIE—DENHAM.—May 14, at 27 Castle Terrace, Edinburgh, by the Rev. Archibald Scott, D.D., St. George's, James Stedman Craigie, M.B., C.M., Musselburgh, to Isabella Eiddle Glover, eldest daughter of James Glover Denham.

Deaths.

COLLINS.—May 10, at his residence, Albert Terrace, Regent's Park, William Job Collins, M.D., aged 66.
COOKE.—May 13, at 107 Grafton Street, Dublin, William Davis Cooke, L.A.H. and L.M., only son of Dr. Cooke, of Clonmel.
MANSON.—May 9, at Baglstone, Strathpeffer Spa, N.B., David Manson, M.A., C.M., M.D., aged 45.
MASSEY.—April 27, of scarlatina, at the London Fever Hospital, Henry Massey, M.D., of Portrush, aged 32.
MULHOLLAND.—May 14, at his residence, 41 Prospect Terrace, Belknap, Cunningham Mulholland, M.D.
MURE.—May 10, at 40 Teddorth Square, London, John Mure, M.D. Ed., Inspector-General of Hospitals (retired).
PHILLIPS.—May 13, suddenly, at Bromley, Kent, Christian Gibson, wife of Robert E. Phillips, M.D.
PINK.—May 6, at Crooms Hill, Greenwich, Henry Northover Pink, M.R.C.S., aged 67.
TWING.—May 12, at the Chestnuts, Walthamstow, Edward Twing, M.R.C.S., aged 66.

THE HISTORY OF ANÆSTHETICS.

By W. ROGER WILLIAMS, F.R.C.S.,
Surgical Registrar to the Middlesex Hospital.

Among those present at Dr. Wells' ill-fated trial of the gas at the Boston Hospital were his former pupil and partner Dr. Morton, and Dr. Jackson, Professor of Chemistry—names destined to play an important part in the subsequent development of anæsthetics. (a)

Desiring in 1846 to use the gas in dentistry, Morton applied to Wells for instructions how to make it. Wells referred him to Jackson, as the latter was a scientific man and an able chemist.

Jackson advised him to use *sulphuric ether* instead, as it possessed the same properties, and was as safe and easier to get. Acting on Jackson's suggestion, on September 30th, 1846, Morton painlessly extracted a bicuspid tooth from a man named Eben. Frost. Thus the anæsthetic properties of ether were first made known. (b) In the following October, several important surgical operations under its influence were performed at the Boston Hospital, Dr. Morton being the administrator, and this introduced the practice throughout the world. It was first used in this country on December 19th, 1846, for the extraction of a tooth at the house of Dr. Boot, in Gower Street, by Mr. Robinson, who administered the ether and performed the operation. (c) A few days later it was successfully used by Mr. Liston, at University College, for amputation of the thigh and evulsion of a toe-nail. Malgaigne and Velpeau employed it in Paris very soon afterwards, and in a remarkably short time it was in use nearly all over the world.

(a) Official Documents, appended to Dr. Morton's volume, pp. 11, 14, 15, &c.

(b) "Report of the Committee of the Medical Association of South Carolina for Investigating the Claims of the Original Discoverers of the Anæsthetic Properties of Sulphuric Ether, &c. Vide *Philadelphia Medical News*, May 12, 1883; also Dr. Wells' pamphlet on Nitrous Oxide, &c. pp. 7 and 8.

(c) Vide *Lancet*, January 2, 1847; and all the medical periodicals of that year.

Probably no great improvement in the practice of medicine ever was established so rapidly. This may in a measure be accounted for by the fact that the properties of ether were not altogether previously unknown. It had often been inhaled, both in America and elsewhere, as an excitant. In 1818 (a) Faraday pointed out that the effects of inhaling its vapour were similar to those produced by nitrous oxide gas; and it was subsequently customary in the college courses, both in Europe and America, to illustrate this fact by various experiments. The resemblance between the action of nitrous oxide and that of the vapour of ether was therefore well-known.

Dr. Wilhite, now of Anderson, U.S.A., was the first who produced anæsthesia with ether, which was done accidentally in 1841.

Dr. Long, an English practitioner, residing in the United States, was the first who performed a surgical operation while the patient was completely anæsthetised by the inhalation of its vapour. This was in 1842. Dr. Long did not hit on this discovery by accident; he reasoned it out in a philosophical and logical manner. Unfortunately, he neglected to publish any account of the experiment. There is, however, no doubt about the accuracy of the facts as above stated. (b)

Dr. Marcy also forestalled Morton by using ether as an anæsthetic in 1844. (c)

Such then are the isolated antecedent facts as subsequently brought to light, when the practice of ether inhalation had been established by Morton, to whom, in my opinion, the chief credit is due; for the history of all great discoveries shows them to have cast similar shadows before.

In January, 1847, and the subsequent spring months, sulphuric ether was first used as an anæsthetic in obstetrical practice by Sir J. Y. Simpson, of Edinburgh. (d)

In the course of this year ether inhalation became more general, so that, in spite of a certain amount of opposition

and mistrust, there is every reason to believe it would very soon have obtained the complete confidence of the medical profession and of the public, but for the introduction of a new agent—*chloroform*.

The anæsthetic properties of this substance were first made known by Sir J. Y. Simpson in a communication to the Edinburgh Medico-Chirurgical Society, on 10th of November, 1847. (a) From the time he first saw ether inhalation he had been on the look-out for an efficient substitute for it; and he made a variety of experiments with various substances to this end. Among other substances he tried chloroform on the recommendation of Mr. Waldie, (b) of the Apothecaries Hall, of Liverpool, as he stated in a foot-note to his first pamphlet on the subject, which was omitted from his original communication, and from his subsequent writings.

Some months previously, Flourens had communicated to the Paris Academy of Science an account of his experiments on animals with this substance; but he was so struck with its great and dangerous properties, that he was far from recommending its use in surgical practice. A weak solution of chloroform in alcohol—called chloric ether—had, early in 1847, been successfully used by Mr. Jacob Bell, of Leeds, for producing anæsthesia; but the true nature of this compound was not then known.

From the general tenour of Sir J. Y. Simpson's writing rather than from any direct statement, which he avoided making, an impression arose that chloroform was safer than ether. It was immediately used everywhere to a greater extent than ether ever had been. It quickly supplanted the latter, not only in Scotland and England, but in the rest of Europe, and, indeed, of the world, with the exception of America, where, fortunately, ether always maintained its ground. In the light of subsequent experience there can be no doubt that this supersession of ether by chloroform was a great misfortune, which has already cost the world many valuable lives—and is still costing. By those best acquainted with the subject this was soon suspected to be the case. In 1848, Dr. Snow, then the highest authority on this subject, expressed himself as follows:—(c)

"The great strength of chloroform as compared with ether, and the extreme care required in its use, were indeed soon pointed out; these precautions, however, attracted but little attention till the first death from chloroform occurred near Newcastle on the 28th of Jan., 1848. Ether was exhibited by inhalation during eleven months in Europe, and about sixteen months in America, before chloroform was introduced. During all this time no death was occasioned by its use, if we except one at Auxerre, in France, which appeared to have been occasioned by want of air, owing to an imperfect inhaler, and not by the effect of ether. Chloroform had only been employed between two and three months when the above-mentioned death occurred, and this was soon followed by others in nearly all parts of the world. These accidents have prevented many persons from inhaling chloroform, and they have prevented a still greater number from enjoying that freedom from anxiety and apprehension before an operation, which ought to be one of the greatest advantages of any plan for preventing pain. As chloroform possesses advantages over ether in being more convenient and less disagreeable, it continues to be used to the exclusion of the latter agent in most parts of the world."

The concurrent testimony of subsequent observers has but confirmed the justice of these remarks. Schiff's numerous experiments on animals points to the same conclusion. It is now universally admitted that chloroform is a much more dangerous anæsthetic than ether; therefore it seems desirable to discontinue its use in all but a few special cases.

As to the precise amount of risk involved in the admin-

istration of chloroform the following remarkable statements have been made. They are chiefly of interest as illustrating the extraordinary fallacies into which the numerical method may lead even the cleverest and most painstaking men. According to Flourens, the French army in the Crimea, with more than 25,000 administrations, had not a single death. Wellford states that, during the American civil war, the Confederate army, with 22,000 administrations, was equally fortunate. Nussbaum is gravely credited with 15,000 administrations; Billroth with 12,500; and Guy's Hospital with 12,000; each without the loss of a single patient. At length, it occurred to some one that an occasional death ought to be recorded. The Royal Infirmary of Edinburgh set a good example, with its modest estimate of one death in 36,500 administrations. For German hospitals, Kappeler has admitted one in 19,500; and Squibb, for American ones, one in 11,764; whilst Lyman's estimate from English and American sources, was one in 5,860. Richardson, dealing only with English hospitals, reduced the number to one in 3,196, and subsequently to a lower figure. Coles and Andrews, on the basis of English and American statistics, put it at one in 2,873 and 2,723 respectively. Lastly, Rendle, including only London hospitals, cut it down to one in 2,666; and here the matter has since rested.

My own experience has led me to make a further considerable reduction. (a) After a careful examination of the subject from different points of view, I have estimated the number of times a year anæsthetics are administered at the subjoined hospitals, roughly, as follows:—The London, 2,500; St. Bartholomew's, 2,200; Guy's, 2,000; Middlesex, 700; University College, 600. Three deaths a year at the large hospitals during the administration of anæsthetics, though not of common occurrence, have happened several times of late. For example, at the London in 1870, and again in 1875; at Guy's, at St. Bartholomew's and at the Middlesex in 1882; and at University College in 1877.

Two deaths a year occurred at the London in 1877, 1878, and 1881; at St. Bartholomew's in 1878; at the Middlesex in 1872; and at University College in 1870.

At the London Hospital 16 deaths (3 under ether and 13 under chloroform) have been reported in the journals during the last thirteen years, being a mortality on the basis of the above estimate of one in 2,031.

St. Bartholomew's Hospital has had 8 deaths (5 under chloroform and 3 under ether) during the last 8 years, or one in 2,200.

At Guy's Hospital the deaths under anæsthetics amount to one or two a year. (b) This will give a mortality of one in 1,333. In 1882 there were 2 deaths under chloroform and 1 under ether.

The Middlesex Hospital has had 8 deaths reported during the last 15 years (chloroform 5, ether 1, methylene 2), or one in 1,312.

Lastly, at University Hospital, during the last 13 years 9 deaths are reported (8 under chloroform and 1 under gas and ether), or one in 866.

To sum up the average mortality of these various hospitals will be one in 1,600. Of 44 recorded deaths, 33 were under chloroform, 9 under ether, and 2 under methylene.

Of course, it may be held, and with some plausibility, that in a certain proportion of these cases death resulted, not from the effect of the anæsthetic, but from the shock of the operation, the severity of the disease, the feebleness of the patient, &c. But, inasmuch as there are no reliable data for making such distinctions; it seems best to speak of all such fatalities as occur during the administration of anæsthetics, not obviously due to other causes, as deaths under this, that, or the other anæsthetic.

These figures furnish no precise information as to the

(b) *Vide Lancet*, May 12, 1883, in reply to the Glasgow enquiry.

relative danger of the various anæsthetic agents. It has been recently stated, on the basis of somewhat antiquated and not very reliable Anglo-American statistics, that the death-rate for chloroform is one in 2,873, and for ether one in 23,204.

The only perfectly reliable statistics on this subject are those of St. Bartholomew's Hospital, where a careful record has been kept of all cases for the last 8 years. They show a mortality of one in 1,446 for chloroform, and one in 3,049 for ether. It is surprising to find that no attempt has hitherto been made to collect similar information at the other hospitals. Surely the subject is well-worthy of attention.

It cannot be too widely known that these figures are totally inapplicable to obstetrical practice, when, indeed, any untoward result is of singular rarity.

As a substitute for chloroform the so-called *Bichloride of Methylene* was introduced by Dr. B. W. Richardson in 1867. (a) Of late it has been extensively used by Sir Spencer Wells (b) and others. It has been found more rapid and evanescent in its action than chloroform, and less likely to cause vomiting and other objectionable symptoms. It is said to be safer than chloroform; but nine, at least, deaths have already been reported from its use in this country. (c) These repeated fatalities would certainly have led to its complete abandonment here but for the advocacy of Sir Spencer Wells. He has now used it in over 1,200 serious operations without a fatal accident. So much, then, on the score of safety. It has long been recognised as a mixture of some sort. According to the latest analysis by Professor Regnault (d) it consists of seven parts of chloroform and one part of methylic alcohol by weight, or for parts of chloroform and one part of methylic alcohol by measure.

Bromide of Ethyl and *Dichloride of Ethiden* have likewise been successfully used as anæsthetics in a considerable number of cases.

Among other substances the following have been tried:—amylene, chloramyl, benzine, aldehyde, disulphuret, of carbon, iodide of ethyl, and butyl chloride.

ON THE INCREASE OF INSANITY; WITH SOME SUGGESTIONS FOR THE REFORM OF OUR LUNACY LAWS AND PRACTICE. (e)

By T. MORE MADDEN, M.D., F.R.C.S.E.,

Obstetric Physician Mater Misericordie Hospital, Physician Hospital for Sick Children, formerly Examiner in Obstetric Medicine, Queen's University Ireland, and former Vice-President Dublin Obstetrical Society.

(Concluded from page 485.)

THE first Act of Parliament providing for the insane, was the 17 George II., c. 5, commonly known as the Vagrant Act of 1744. By this any two justices of the peace were authorised to confine, and, if necessary, chain any dangerous lunatic, and to apply the property of the lunatic to his maintenance. Eleven years later, by the 14 George III., c. 49, and again by the 26 of the same reign, c. 91, lunatic asylums in, or about London, were required to be licensed and inspected by the College of Physicians. In 1828, the control exercised by the College of Physicians was transferred to a body of fifteen commissioners, and medical officers were required to attend all lunatic asylums. Subsequently, this Board was superseded in 1833 by the Metropolitan Commissioners in Lunacy, appointed by the 2 and 3 of William IV., c. 107, and in 1843 their powers were extended to all lunatic asylums in England and Wales. Ultimately, in the following year by Lord Shaftesbury's

Act, or 8 of Victoria, c. 100 and 126, the present Board of Commissioners in Lunacy over which Lord Shaftesbury presides, and, which consists of three medical and three legal paid commissioners and other unpaid commissioners, was appointed; and charged with the supervision of the vast lunacy system of England and Wales. This Act was further amended by the 16 and 17 Victoria, c. 96, and the 18 and 19 Victoria, c. 105. Amongst the other duties thus imposed upon these commissioners, is that of visiting lunatic asylums in or about London quarterly, and those throughout the rest of England and Wales twice annually.

The Irish lunacy laws date only from the 1 and 2 George IV., c. 34, by which district public asylums and a central criminal lunatic asylum were established in Ireland. By the 7 George IV., c. 90, the inspectors of prisons were charged with the duty of annually visiting and reporting on all madhouses or places where lunatics or idiots were confined. By the 5 and 6 Victoria, c. 23, further provision was made for the licensing and inspection of private lunatic asylums in Ireland, and in 1845, by the 8 and 9 Victoria, c. 107, sec. 23, to the present inspectors of lunatics, the control and supervision of Irish lunatic asylums was transferred.

The appointment of officers of district asylums and the custody of dangerous lunatics were provided for by the 30 and 31 Victoria, c. 118. The management of the estate of lunatics and proceedings under commissions of lunacy are regulated by 34 and 35 of Victoria, c. 22. And by the 38 and 39 of Victoria, c. 67, certain amendments were made in the former laws, relating to the detention of lunatics in public or private asylums. At the same time powers were given for the enlargement of patients on trial on certain conditions, for the detention of chronic lunatics in workhouses, and also for making the property of lunatics in district asylums available for their maintenance.

I shall now add a few observations with reference to the proportions which our lunacy system, as represented by the public and private asylums of Great Britain and Ireland, has reached. I may also refer to the enormous and yearly increasing burden, which by the former is now imposed on the long suffering tax-payers of these countries; and the urgent necessity for certain reforms which would improve the administration of such asylums and benefit the condition of those therein confined, as well as diminish materially the amount of public funds now expended on these institutions.

In so doing, it might be interesting to glance briefly at the rapid stages by which this system has attained its present magnitude. The first, and for many years the only madhouse in England was Bethlehem, of which a committee appointed to inquire into its condition in 1598, reported that the house was loathsome and dirty, and that it was not fit for any man to enter. In 1675, New Bethlehem was opened, and down to the year 1770 the inmates were publicly exhibited, first for twopence and subsequently for one penny a head for admission to all who wished, as Dr. Connolly says, to enjoy that sight. By an Act of 1774 already cited, some attempt was made, apparently without much effect, for the removal of these abuses which, as Dr. Connolly in his learned and eloquent disquisition on this subject has shown, continued down to the commencement of the present century. At length, however, at the Friends' Retreat for the insane, near York, it was demonstrated by Mr. Tuke that "these unfortunate persons might be advantageously treated with kindness and humanity."

From that time institutions for the insane, public and private, sprung up on every side, and vied with each in carrying out the humane and kindly system thus introduced in the York Retreat.

In Ireland, up to the year 1708 there was no provision for the care or custody of the insane. Sir William Fownes, in a letter to Dean Swift, says:—"When I was Lord Mayor of Dublin in 1708, I saw some miserable lunatics exposed to the danger of others as well as of themselves. I then had six strong cells made at the

(a) *Medical Times and Gazette*, 1867. Vol. II., pp. 423, 434, 479, 693.

(b) *Lancet*, 1871. Vol. I., pp. 591, 634, and vol. II., 638; also 1877, vol. II., p. 191. See also Sir Spencer Wells' work on "Ovarian and Uterine Tumours."

(d) "Bulletin de l'Académie de Médecine de Paris," Avril 24, et Mai 1, 1883.

(e) Read before the Academy of Medicine in Ireland.

workhouse for the most outrageous, which were soon filled, and by degrees, in a short time, these few drew the solicitations of others, and in 1728 we had in the house forty and upwards (Wild's "Closing Years of Dean Swift," p. 80). The second attempt to provide for the custody of the insane in Ireland, appears to have been in 1711, when cells were made at the Royal Hospital, Kilmainham, for military lunatics. In 1776, ten cells were built for lunatics in the House of Industry, Dublin.

In 1778 this number was enlarged to thirty, and from the general increase of insanity in the troubled times of the Irish rebellion in 1798, it became necessary to add thirty additional cells for lunatics. In 1798 a lunatic asylum was also erected in connection with the House of Industry in Cork. And in 1810 the Richmond Lunatic Asylum was commenced, this was completed in 1814 by aid of a parliamentary grant of £77,000. When the first Inspector, under the Act of 1821, commenced duty, the only public asylums for the insane in Ireland were the two mentioned in Dublin and Cork.

How great is the contrast between these small beginnings and the present extent and number of our lunatic asylums, public and private.

There are now 101,096 registered lunatics in Great Britain and Ireland, of whom 90,869 are maintained at the public expense. Of these 68,846 are in English or Welsh asylums, 8,853 in Scotland, and 13,171 in Ireland. The cost of the support of the public asylums of England last year was no less than £1,033,780, whilst the Irish public asylums are supported at a yearly cost to the taxpayers of £200,000.

The object of these asylums and of this lavish expenditure of public money is to secure the safe custody and curative treatment of the insane, who in their own interest, as well as for the public weal, require restraint in such institutions. I would therefore suggest that these purposes would be better effected, at less cost to the public, were private lunatic asylums abolished by making these first and second class state or public institutions, and part of the system under which the existing public or pauper county and borough lunatic asylums are now administered.

None who have had the opportunities I have had, of visiting the medical institutions of other countries, can fail to return home better pleased with the general good management of our lunatic asylums, public and private, and, with the kindly treatment of the patients in most of them. Nor is it possible to withhold our sympathy from those who, in some instances with great self-sacrifice, devote themselves to the care of the helpless victims of insanity in such institutions. At the same time, however, I have no hesitation in saying that medical men are necessarily placed in a false position when acting either as medical superintendents of public lunatic asylums, or as proprietors of private ones. The duties of the former are most anomalous and complex. The functions of the medical superintendent of a county or borough asylum now comprise those discharged in a workhouse by a master, or in a prison by the governor, or in a model farm by the head steward, with those of secretary to a board of governors. Moreover, they also include all the professional duties appertaining to the house surgeon or resident physician of a great hospital, superadded to which is the performance of whatever special work may be imposed on him as a medical psychologist in charge of insane patients. It is obvious that no person could properly discharge all these duties.

The position of medical proprietor of a private asylum is still more anomalous and difficult. For it includes all the varied and incongruous duties just referred to, and these, moreover, in his case have to be discharged under an inseparable sense of personal pecuniary interests.

If, in Lord Shaftesbury's words in introducing his

Lunacy Act in the House of Commons, "pauper lunatics should be maintained at the public cost, and not be received for profit or as the objects of financial speculation" then there can be no cause why the insane of the middle or upper classes should be differently circumstanced in this respect. The only justification for the imprisonment of lunatics rich or poor is their own welfare and that of society, and no vested right or other interest should be allowed to influence this. Vested rights far greater than those of the proprietors of private lunatic asylums have been very summarily dealt with by Acts of Parliament within the past few years. Hence if the public welfare appears to demand the abolition of private lunatic asylums there seems no reason why their proprietors, being first of course fairly and fully compensated from the public funds, these institutions should not be transferred to the direct administration of the Commissioners in Lunacy, and governed by them as first or second class public asylums. The surplus profits of these institutions might then be made available towards the support of the non-paying or pauper asylums under the same central administration, and thus help to relieve the public funds from some part of the enormous and yearly-increasing cost of our present system of pauper lunatic administration and maintenance. In such institutions the medical functions now discharged by the medical superintendents should be transferred to officers analogous to the masters of workhouses or governors of prisons. At the same time being thus relieved of all extra-professional duties, the medical superintendent should become a resident physician, and be enabled to devote himself to the care and treatment of the patients, in which he should be only subject to the advice and control of a medical board of visiting physicians and surgeons. Amongst the latter, in the case of female lunatic asylums, there should for reasons already stated be appointed one or more visiting physicians who have had some clinical experience of the diseases peculiar to females.

Another desirable reform would be in the direction of the non-restraint in lunatic asylums, though still under supervision, of a large proportion of those chronic and harmless patients now confined therein. Many of these, especially of the weak-minded or semi-imbecile class, might be as well treated, and could be maintained in greater personal happiness and comfort, as well as at considerably less cost outside the walls of lunatic asylums.

Did time permit, I should have been glad to refer further than I now can to the unsatisfactory state of the laws relating to so-called criminal lunacy and the criminal responsibility of the insane. Many years ago I published a communication on this subject in the Proceedings of the Medical Society of our College of Physicians, and since then some of my views and suggestions have been endorsed, or rather, have been appropriated, by others.

It should be needless to argue that the medical jurisprudence of insanity comes within the province of our discussions in this Academy. Mental operations are accomplished through, and are to some extent modified by, the state of the cerebral organisation. Hence disorders of the mind act upon the bodily health, and physical diseases in their turn react on the mental functions. This, however, is yet unrecognised by those who make and those who administer our laws. And judges and lawyers still complacently propound as a truism their fallacious aphorism that "insanity is a fact, and not a disease," and that its existence in any case is to be determined in other facts by the common sense of jurymen, not requiring special knowledge for its investigation. Accordingly, we find ignorant jurymen thus directed by judges who, however learned and eminent in the law, are in this matter little better qualified than the jury, deciding in even cases involving the issues of life and death one of the most difficult of

scientific questions, without any knowledge of the significance of the facts on which their judgment is founded.

The difference between those who possess merely good, plain common sense to direct them in deciding the question of sanity or insanity and those who rest their opinion on scientific knowledge and experience, is analogous to the difference between the power of determining a ship's position at sea by astronomical observation by the skilled mariner and the helpless ignorance of an untaught landsman in his first voyage. Both may contemplate the same natural phenomenon, but the one aided by science and experience is able to deduce therefrom accurate knowledge of a fact concerning which the other, however much good common sense he may possess, can know as little as the lawyer or jurymen generally does of the sanity or insanity of any person who may be brought before him in a court of law.

The danger that lunacy may be easily feigned, and that this may lead to the failure of justice in criminal cases, is an idea generally predominant in the legal mind, and frequently operates to the prejudice of those in whose case this plea is raised. It would be easy to show how groundless this fear is. It certainly may be, and frequently is, very difficult to detect madness in cases where it actually exists. But it is almost impossible for anyone to feign insanity so as to deceive experts in this matter.

There are other questions connected with the medical jurisprudence of insanity to which only the lack of time and the length of this paper now prevents my referring. I may, however, in conclusion, again observe that any future amendment of the laws relating to criminal lunacy should be based on the broad principles of the French criminal law as expounded in the 64th article of the Code Napoleon, viz.:—"Il n'y a ni crime, ni délit lorsque le prévenu était en état de démence au temps de l'action." Finally—medical assessors in lunacy should be appointed with functions analogous to those of the nautical assessors in marine cases. In Ireland these might be the Inspectors of Lunatics, or in England and Scotland the Medical Commissioners in Lunacy, and such assessors should assist and advise in all trials in which the question of lunacy is raised.

CONSUMPTION VIEWED IN RELATION TO EVOLUTION AND MOLECULAR ENERGY.

By WILLIAM H. PEARSE, M.D.,

Senior Physician to the Plymouth Public Dispensary.

(Continued from page 489.)

Heat-Neuroses were spoken of far less frequently than were cold, but they were not infrequent in the early stages of those who passed into phthisis. Some patients have said that heat-neuroses were the very first deviations from their ordinary health. Patients have said, "one side burns;" "burn like fire sometimes;" "for months one foot was cold at night, the other burning;" "the right side of head burning for a year past;" "hands and face, on and off, for years have been burning."

Philosophical Method having so deeply taught us, from all other sides of knowledge, the vast importance of the smallest deviations in rate, series, or forms; and that such, if grasped and followed, open to us the most universal laws both in inorganic and organic nature—the mind deeply strives to understand. How arise these cold and hot neuroses; how in the nerve cells do the deviations arise; from what altered state or "mode" of correlated "energy," and from what want of "energy"-giving matter.

Indigestion.—Although physiology or science has not yet traced the exact relations of indigestion, including both the pain and the sinking at the epigastrium, which are so frequent in the pre-phthisical stage, to their more

immediate centres or segments of the nerve system, any more than they have traced the neuroses already referred to, viz., weakness, cold and heat sensations, yet as the human body is, in a grander sense, one indivisible reciprocal system, and as the forms of indigestion are so much associated, in so many individuals, with the other-named neuroses, it seems just that we should class the indigestion with those other nerve deviations or perturbations. If this be just, the very complexity and variety of the phenomena, and occurring so markedly in association, should help us to the perception of the "Form" common to the earliest recognisable symptoms of phthisis. And we shall feel this all the more, when we add to the list of these neuroses the various other most prevailing deviations of the early stages of phthisis, viz., the loss of appetite, inability to eat fats, anæmia, amenorrhœa, &c., &c.

With the development of true Method in this age, and with our greater capacity to see the deeper alliances of phenomena, rather than their immediate and striking differences, the doctrine of the "specific" is everywhere disappearing, whilst greater general "forms" are recognised. The vast frequency and long duration—of years even—of pain at the epigastrium after taking food, in those who eventually pass into phthisis, is a phenomena of the greatest import. Out of about nine hundred cases of phthisis—and real and approximate pre-phthisical cases—one hundred and forty-four had suffered much from indigestion, that is, pain at the epigastrium after taking food. Of the same classes, fourteen said that they had never known indigestion; eight of these fourteen were actual and advanced phthisis. "Sinking" at the epigastrium, sometimes intense, is less frequent than pain. Some few cases have presented with very severe and long-continued indigestion, simulating ulcer of the stomach. In one such, the symptoms lasted several months, but somewhat suddenly disappeared. I thought coincident with the development of considerable phthisical-like moist râles in the lungs, and strumous affection of the sterno-clavicular articulations. Some complained of indigestion after exertion; others in the morning. In one case of advanced phthisis it had only lately shown.

The Appetite.—Failure of appetite for years is a very common symptom. Patients in pre-phthisis will say—"appetite for food is entirely gone;" that "it has been gone for years;" that they "never feel hungry;" and yet there may not be marked wasting. In this symptom we have indication of an absolute and most prevailing part of the complex phenomena we call phthisis. Can the physiologist or the vito-chemist give us any definite facts as to how this symptom exists? on what defects of composition, correlation, or "energy" does it depend? Although we recognise the human body as one organ, one system, in which every part reciprocally correlates with every other part, and with the whole, not the less do we recognise that certain parts have greater commanding correlation over and with local organs. Can we see then from physiological, pathological, or chemical stands, any near or determining conditions or causes on which this loss of appetite depends? That such a symptom can be reached and influenced by change of air, say, to Dartmoor, or by quinine, muriatic acid, &c., shows its deep correlation with molecular and nerve changes, and is an experimental entrance or advance toward the true "form" of the disease.

Practically, it is important to observe the varieties of appetite; and it might further happen that they might help us to differentiate the potential deficiencies in the composition, and the vital power of those who do, from those who do not, pass, so gradually, into phthisis; such differences in appetite must have absolutely definite vito-physical causes or conditions. Wide generalisations have been reached in as seemingly complex phenomena in physics, in the forms and modifications of leaves, in comparative language; and we are sure

that a general order and relation must exist between the correlations of matter and symptoms.

Pre-phthisthal and phthisthal cases sometimes show a change of type of appetite. A not uncommon statement is, that they are hungry only at night. I always encourage such cases to eat at night if they so prefer, and if it agrees with them. I have never heard a complaint of this practice.

Of all the subjective phenomena associated with phthisis, and often for a long series of years, in the pre-phthisthal, there are few more striking than the prevailing passion for onions. I could fill columns with the emphatic statements of patients as to their great craving for onions, and their thorough agreement with their digestion and system. Of those asked, one hundred and seventy-nine had this desire, against thirty-four who had not; but such numbers do not at all convey the passion which many of the pre-phthisthal have for them. There is no other more marked craving of the system. Nature never speaks in vain; and I have no doubt that there exists some "nascent" condition, some state of molecular "energy" in the onion, which goes near to supplying the body with the true correlative for healthy growth. Such is the craving for onions, in many of the phthisthal, and such their agreement with the system, that I do not doubt but that it is an instance parallel with that of the Swiss, who by some instinct, or insensibly evolved experience, ate burnt sponge to cure their gout; or parallel to the passion of the low-fed semi-scorbutic Hindoo for tamarind and lime-juice. Pickles, pickled onions, vinegar, and salt and smoked meat and fish, are also craved for and agree, when fresh meat is loathed. Dutch cheese is much liked; I have often had pre-phthisthal and phthisthal patients who will eat a hearty supper of Dutch cheese and pickles. I have often known such diet debarred, but I do not remember ever hearing a patient say that it disagreed, where the craving existed. I remember when European medical fashion in India debarred the native from the tamarind and lime-juice which he beseechingly asked for, lest they should cause cholera, dysentery, &c. ! the truth being that those very acid fruits were the all-essential wants of his system, and without which he almost inevitably passed into chronic diarrhoea and chronic dysentery. I hold strongly that it is a parallel error to withdraw such food as onions, pickles, vinegar, salad, salted and smoked meat from the pre- and actual phthisthal, in cases where they are craved for. A plant to be in perfect health must have its elective essential elements in the soil; the amount may be extremely small, but that amount is all-essential to health, life, and "survival." The very smallest secular changes are the occasions or courses of the greatest operations in Nature; nor is the human body exempt from parallel laws. The "unstable equilibrium" of vital energy is seen in the not-infrequent desires for marked changes in food; to rest content by saying that such phenomena are "caprices" is but to deceive our minds by words.

But the great fact in the pre-phthisthal is the general inability to eat fats; but not all fats, for butter is nearly always liked, and so very often are the fats of roast pork and well-fried bacon. Take this common case—A young woman died, at twenty-one, of phthisis; from her very childhood she could never take fats; every bit of fat she would carefully put aside. This phenomenon is as much a part of the full "form" of phthisis as is the destruction of the lung itself. Did we know its full series of correlations we should be on the path of its prevention. One or another organ of the *primæ viæ* may be in more immediate relation to the phenomena than others, but we shall seek in vain if we limit our view to the liver or other organs, because such organs or glands are not isolated from the greater general organic life of the whole system; nerve and molecular "energy" are deranged, and such great deviation of function may result from difference in com-

position so minute, as to be wholly immeasurable by any galvano-electric pile yet produceable. Function alone is sensitive enough to be its measurer!

It is of great consequence to dwell on such phenomena as this repugnance to fats, because at any moment its correlations to nerve supply and nerve centres may be discovered, and knowledge of remedies may be suggested from collateral but interlaced facts. Out of many hundreds asked, only three phthisthal and three pre-phthisthal cases said that they could eat fats with relish. With these cases now before me I am not able to differentiate the condition which led to this "variety" (species) in the (genus) appetite.

It is important to state that many cases complaining of "weakness" get much relief from the special kind of food for which they crave. I am obliged to say further that many an exhausted pre-phthisthal poor woman who sits down to her supper of Dutch cheese, pickled onion, or raw onion, and bread, will get great good from her half pint of stout. I am obliged to subordinate my individual wishes as a teetotaler to the facts which practice and observation present. When a poor woman in phthisis, labouring on in her duties and work, tells me that she enjoys her dinner and supper the better for a little stout, I am in duty imperatively compelled to allow it; and I hear such statements continually. I know of no substitute. She enjoys her meal better and is *happier* with the glass of stout; nor are these frames of mind in themselves small therapeutic remedies. Scientific chemistry and physiology have hardly yet touched the deeper and delicate problems on which the practitioner has to decide; the cravings and confessed experiences of the body must have their just weight. If we can make one or two meals a day to be more enjoyed by the patient, and can do this regularly over a period of months and years we shall be doing a great deal to sustain the waning vigour, and probably prolong the years, of the patient. The individual patient is our post of duty, and not the general campaign; and beer and wine may be of immense good and have, in certain cases, no substitutes. I see many middle-aged people of the poorer classes in phthisis who work on for years with but little or any progress of destruction of the lungs; and I am thereby deeply impressed with the great importance of seemingly almost insensible remedies, as they are related to warmth, pure air, out-of-door life, cheerfulness, and the employment of food which they enjoy.

(To be continued.)

Clinical Records.

A CASE OF DOUBLE VAGINA. (a)

By WM. JAS. SPENCE, L.R.C.P., &c.,
House-Surgeon, Bradford Infirmary.

MARY W—, æt. 26, a weaver, attended as an out-patient at the Bradford Infirmary on February 25, 1884, complaining of a tumour in the vagina. The patient, a spare, delicate-looking woman, gave the following history:—

Menstruation commenced when she was 13 years old, and has continued, with the exception of the periods when she was pregnant, at regular intervals ever since. She married at the age of 19, and has had six children. The first five were premature (about the 7th month), the sixth, a female child, born at full time, died of fits at seven months old. None of the children were in any way malformed. A midwife attended her in all the confinements. It is about two years since the last child was born, the labour was not a hard one, but she says the midwife "hurried her." She remained in bed nine days, and upon getting up on the tenth day discovered what she describes as "something wrong," a substance protruding from the vagina, and sent for the

(a) Read before the April meeting of the Bradford Medico-Chirurgical Society.

midwife, who told her it was only weakness. She is not aware that there was anything wrong before this.

The tumour is largest when in the erect position, slightly receding when recumbent, but never disappearing entirely. It has not increased in size since first noticed, and has never caused any pain, but she is troubled with a constant dragging sensation in the lumbar region, and more or less leucorrhœa. Upon digital examination, per vaginam, a flattened growth, about the size of a large compressed fig is felt protruding from the vulva. It is attached to the posterior wall of the vagina, a little to the right of the median line, and extends from the external orifice to the cervix uteri, but is not attached to, or connected with, the os. On the anterior wall there is a fold of membrane, which is also slightly to the right, extending from above the meatus urinarius to the cervix. At the commencement it is ill-defined, but increases in depth as it ascends. The os is normal in position and appearance, and the sound passes 2½ inches into the cavity of the uterus.

On March 3rd, the patient was admitted as in-patient under Mr. Spencer. He recommended removal, and kindly asked me to do the operation. This I did on the following day (March 4th), by means of the écraseur. There was nothing remarkable about the operation, it was performed in the usual way, and was followed by little or no hæmorrhage. No sutures were used, the wound was simply allowed to granulate, the only after treatment was rest in bed and injections of luke-warm water containing Condy's fluid. The parts healed rapidly, and were quite sound within the fortnight. Upon examination of the growth, after removal, it was found to be irregularly flattened with a great resemblance to the pinna of the ear in shape. The surface was deeply wrinkled. The base, or part where the tumour was attached, measured a little over two inches in length, and the free edge was fully half an inch longer. The thickness varied from half an inch at the broadest part of the base, to less than a quarter of an inch at the apex. The free edge appeared to consist of cicatricial tissue such as you would expect to find if the growth had been cut or torn short, and left to itself to heal. Upon section the tumour appeared to consist principally of connective tissue of fibro-cellular type, with an external layer of mucous membrane.

I think there can be little doubt as to the nature of the tumour, the history, the shape, the fold of membrane on the anterior wall of the vagina, which, at one time had evidently been continuous with the growth on the posterior wall, and last, but not least, the structure, all point to one conclusion, viz., that it was the remains of a vertical septum, which, prior to the last confinement, had divided the vagina into two almost equal parts. I have looked through a great number of text-books and journals, but can find no reference to a similar case. In all the cases of double vagina recorded, the duality has extended to the uterus.

Transactions of Societies.

WEST LONDON MEDICAL CHIRURGICAL SOCIETY.

Dr. J. L. W. THUDICHUM, President, in the chair.

At the April meeting of this Society a paper was read by Mr. NOBLE-SMITH ON

THE TREATMENT OF TALIPES.

He endeavoured to make his remarks as practical as possible, and to avoid discussing all the various possible plans of treatment. He was convinced that when a surgeon meets with a case in which the tendons are tense and resistant, the sooner tenotomy was performed the better. He referred to the important subject of the position in which the foot should be placed after tenotomy. If it is placed too near the original position of deformity, leaving the elongation of the tendon to the process of stretching, a great risk is run of contraction, a condition which is much more difficult to cure than when the deformity is treated for the first time. Upon the other hand, if the cut ends of the tendon are separated too much, and pressure is applied on the part between the ends, then there is danger of non-union, and that is, of course, a serious misfortune. Mr. Noble-Smith described a case which he had seen in which the tendo Achillis had been divided

some time before he saw it for talipes equinus; the foot had been fully extended and encased in a plaster-of-paris bandage, and kept there for several weeks. The tendon had not united, and a severe form of talipes calcaneus had resulted. He found it advisable in the majority of cases to place the foot in a nearly normal position, leaving very little to be done by stretching. Many cases could be cured without operation, and plaster-of-paris bandages could be used with benefit in some instances. Mr. Smith advocated simplicity with regard to construction of instruments for club-feet, and he urged surgeons to give more attention to the details of construction, and to leave less to the discretion of the instrument makers than they were generally inclined to do.

Dr. SINCLAIR THOMSON speaking, recommended the removal of a V-shaped piece of bone in varus, as a friend of his in Germany who adopted this plan in young children, and tied the bones together with catgut, had found it very successful.

Dr. THUDICHUM had noticed many cases of syphilitic brain disease in young persons in which contraction of the plantar fasciæ took place to a great degree, and he found them yield to anti-syphilitic treatment without operation.

Mr. BENHAM considered it a settled point in orthopædic surgery that in cases of equino-varus, the varus should be first cured.

In reply, Mr. NOBLE SMITH said he would rather not perform osteotomy if the cases could be otherwise cured. With regard to performing the operation for equino-varus, into two parts he had often seen all the tendons cut at one operation, and generally with bad results. Mr. Noble Smith also remarked that, in his opinion, no operation should be undertaken where nervous symptoms, such as spasms, were present, until those symptoms had first been arrested.

SPECIMENS.

Dr. H. CAMPBELL POPE showed specimens of diseased kidneys. The patient was said to have had no kidney symptoms during life except frequency of micturition, and she suffered from violent headaches. She died suddenly, and at the post-mortem examination it was found that the pelvis of the right kidney was very largely dilated, while the left kidney had several large abscesses, which contained nearly a pint of curdy pus with a small stone. However, the cause of death was found to be hæmorrhage into the brain.

CASE OF PUS IN THE KNEE-JOINT TREATED ANTISEPTICALLY.

Mr. J. R. LUNN showed a case of pus in the left knee-joint, which he had opened antiseptically with a good result. J. E., æt. 45, a shoemaker by trade, admitted into St. Marylebone Infirmary, 1st November, 1883. He stated that he had never had any serious illness, except when a child he had something the matter with his right hip. He had been ill seven days with intense pain in the left knee, which on admission was swollen and very hot. Distinct fluctuation was felt. It was treated with a back-splint, leeches, &c. On the 7th it was aspirated, and 3 oz. of pus withdrawn. On the 8th the joint was opened under the spray, and a large-size drainage tube passed from the highest point of the joint, and a counter-opening made on the outer side of the joint. The joint was washed out with carbolic lotion, 1 in 40, and dressed antiseptically, and the leg was put on a McIntyre's splint.

On the evening of the operation the temperature was 99·8° Fahr. The patient had slight rise of temperature every evening, and on the 22nd it went up to 101°, when an abscess was opened on the outside of the joint. From this date the patient made uninterrupted recovery; the antiseptics were left off 11th December (five weeks and four days from the time of operation), and dressed with a little iodoform, and the knee was put up in a plaster-of-paris splint, which he kept on about two months, and got about in the ward, and was discharged, 14th March, cured, with a very fair movable joint.

During the whole of the operation he had only nine dressings under the spray.

On 28th March Mr. Lunn had seen this patient since his discharge from the Infirmary, and who stated "that he gets about as well as ever."

SURGEON-MAJOR C. A. SMITH, M.D., has been appointed to the charge of the Female Hospital at Woolwich, in the place of Surgeon-Major Quinton, who has been granted six months' leave of absence prior to retirement

BRADFORD MEDICO-CHIRURGICAL SOCIETY. APRIL MEETING.

The President, Mr. W. H. ELLIS, M.R.C.S., in the chair.

Mr. SPENCE detailed

A CASE OF DOUBLE VAGINA,

which will be found at page 490.

After the reading of the case,

Dr. GOYDER said he had an opportunity of examining this case in the O.P. room of the Infirmary, and had found the fleshy mass on the posterior wall of the vagina, but had not observed the corresponding remains of the septum on the anterior aspect. There was no doubt the actual character of the abnormality was such as Mr. Spence had described; the septum seemed not to have been ruptured till the labour at the full time; it was unusual to have a double vagina without double uterus. Mr. Spence explained that it was not till after her sixth labour, which was the first at the full time, that the woman had discovered her "tumour."

Dr. RABAGLIATI then made some remarks on the inefficiency of

SCARPA'S SHOE FOR THE CURE OF CLUB-FOOT,

and exhibited a new apparatus of his own invention, consisting of a sole in two pieces, capable of being lengthened or shortened by a rack and pinion movement, so as to adapt it to the foot, and having straps passing diagonally across to secure the foot being flattened to the sole and to hold the heel effectually down. Since constructing the apparatus Mr. Spence had pointed out the method of Watson of Edinburgh, which was by the adaptation of perforated zinc to the foot, which could be secured at any angle. This seemed to him the best mode of treating the deformity he had yet seen.

The PRESIDENT thought he had seen a similar method to Watson's in the Orthopaedic Hospital two years ago.

Mr. W. G. BURNIE had seen a shoe like the zinc one exhibited in the children's ward of Bartholomew's Hospital. Scarpa's shoe failed because it did not hold the foot.

Mr. MIALI agreed that Scarpa's shoe was unsatisfactory, the reason being that the child's foot was not like that of the adult; the rectangular position did not exist in the child. He had little belief, however, in treating club-foot without operation.

DOUBLE HYDATID CYST IN THE LIVER OF A CHILD.

Mr. WILMOT exhibited the liver of a child that had fallen down, and afterwards vomited and died. As he could not discover the cause of death, a post-mortem examination was ordered, when he found a double hydatid cyst in the liver ruptured. Possibly the child had fallen upon the cyst and burst it, afterwards dying of shock.

Mr. DENBY read a major communication on

ANTE-PARTUM HÆMORRHAGE,

in which he detailed its general disposing causes, varieties, symptoms, course, and treatment. He reviewed the theories of Barnes, Sir J. Y. Simpson, Matthews Duncan, and others as to the source of the blood, and the position of the placenta. With regard to treatment of placenta prævia, about which the paper principally spoke, Mr. Denby remarked that the old methods of forcible delivery with turning and extraction of the placenta were open to grave objections, as the cervix and os uteri were thereby subject to serious injury. He thought the rupture of the membranes alone might suffice in cases where there was active contractile power of the uterus with spontaneous dilatation, and he favoured the use of Barnes's bags.

The PRESIDENT said Mr. Denby had given a very exhaustive paper on the pathology of placenta prævia, and trusted there would be a good discussion.

Dr. GOYDER said Mr. Denby had given an extended and minute paper mainly of the causes of placenta prævia. He understood that one cause of placenta prævia was a lax condition of the uterus, the ovum falling towards the os, and becoming fixed there; hence it was most common in multiparæ. It struck him that the opinions cited from Dr. Barnes contradicted each other. He had had seven or eight cases of placenta prævia to treat, and the character of your action would be determined by the severity of your case. In face of this terrible and imminent danger to life prompt action was essential, and he would rather trust to the steady and patient

action of his fingers and hand in opening the uterus than to Barnes's bags. He had generally turned and delivered before removing the placenta, which sometimes he passed to one side of when not wholly attached, and sometimes through its middle. He thought the chances of safety to the mother lay in quick delivery where the os was sufficiently dilated and careful subsequent bandaging. As a rule, scientific expedients were little thought of on such occasions.

Mr. MIALI did not agree with Dr. Goyder about Dr. Barnes; he thought the bags were a great improvement in the treatment of placenta prævia. The worst cases were those of accidental hæmorrhage, where labour had hardly begun, the os uteri being closed.

Dr. JOHNSTON thought Mr. Denby was to be thanked for refreshing the memories of the members on the subject of placenta prævia. He had met with cases of ante-partum hæmorrhage, and agreed with Dr. Goyder in preferring the hands to Barnes's bags. In his last case there was profuse bleeding before any pains, the case occurred at the eighth month, and he delivered both child and placenta by hand, the child living for a short time after birth. He had no experience of Barnes's bags, but he thought the fingers as safe, and certainly more expeditious.

Mr. W. GILCHRIST BURNIE was sorry Mr. Denby had not time to detail his cases, and that he had confined himself to placenta prævia. In this one could do something to control the hæmorrhage, but in hæmorrhage at the fourth month you could do very little, and it was generally followed by abortion. One case he had was interesting from the fact of the placenta being adherent, showing previous inflammation. In a second case, with hæmorrhage at the second month, a healthy child was delivered at the full time, followed by the placenta.

Dr. MCGREGOR cited a case of placenta prævia in a delicate woman demanding immediate treatment, in which Barnes's bags were applied with very little effect. He plugged the vagina with cotton, but did not restrain the hæmorrhage; forcible delivery had to be resorted to by turning.

Mr. MERCER said Dr. McGregor had undertaken the foregoing case for him, but he was able to assist at its termination. He cited a case in which a woman by stretching had detached the placenta; the hæmorrhage was profuse; he ruptured the membranes with a sound, put on a bandage, turned, and delivered. He had had many cases of placenta prævia and accidental hæmorrhage.

Dr. TIBBITS had had five cases of placenta prævia in five years out of two hundred and forty cases of midwifery. One of the cases died from neglect of application for medical assistance. Dr. Hall Davies recommended rupture of the membranes and plugging in cases of partial placenta prævia. He (Dr. Tibbits) had never found the latter operation satisfactory; indeed, in his opinion it was impossible to plug an elastic passage with anything. His advice was to get the woman out of danger by as speedy a delivery as was possible.

In lieu of reply, Mr. DENBY rapidly read over two cases, both of which were conducted to a safe termination.

THE ANNUAL REPORT OF THE ROYAL COLLEGE OF SURGEONS, IRELAND.

In view of the annual general assemblies of the Fellows for discussing the acts of the Council, and for electing the administrative body for the ensuing year, which will be held on Saturday and Monday, the 31st of May and 2nd of June, it is appropriate for us to notice the annual report of Council just issued to the Fellows.

THE PUBLICATION OF THE PROCEEDINGS OF COUNCIL.

Before doing so we must express the opinion that the presentation of any such report is in itself most unsatisfactory. It is now three years since the Fellows of the College, at the instigation of Dr. Jacob, without a dissentient voice, recommended to the Council to make arrangements by which the progress of the collegiate business might be communicated to the Fellows at the end of each quarter instead of being bulked in one incomprehensible document placed in their hands at the end of the year, and at the moment when they had assembled to discuss it. That resolution was

afterwards pressed upon the Council by Dr. Jacob, and a *precis* of the first quarter's business was drawn up and submitted to them, but its issue encountered a vigorous opposition, because it told the Fellows too much. It was objected to it that it contained division lists, the inference being that those Councillors who voted on certain most critical questions within that quarter would rather not have their votes submitted for the criticism of the Fellows; and a further objection was raised that it gave the names of proposers and seconders of resolutions, and thus brought pointedly under the notice of the Fellows those Councillors who busied themselves about the work of the College as distinguished from those who seldom attended Council, and when they did attend, did nothing. In consequence of this opposition the *precis* of the quarter's business was first emasculated by the removal of the obnoxious lists and names, and was finally withheld from publication.

The demand for a more complete, frequent, and business-like publication of the Council's proceedings was renewed by the Fellows at the general meeting in last June, and a committee of five Councillors (from which Dr. Jacob was carefully excluded) was appointed to report to the Council on the subject. Whether the committee ever met or made any attempt to perform the duty entrusted to them does not appear, but they certainly did not make any report to the Council, and, therefore, the request reiterated by the Fellows does not seem to have received the compliment of being considered at all, much less being acted upon.

We hope, therefore, that the Fellows will, on this occasion, make their influence and determination felt with reference to this matter in the coming meeting of the College, and that they will give their instructions to the new Council in such peremptory form that they cannot again be trifled with. If they will refer to the report which has been placed in their hands, they will find good reason for active interference. In the first place they will see that a series of bald resolutions and amendments are laid before them without any information whatever as to balance of opinion in the Council thereupon. For instance, on the question of voting by papers, which has evoked so much heated discussion, and which has already been made the subject of letters and circulars to the Fellows, they are given no information as to the names or even numbers of voters on the division which took place in the Council on the subject, and the same may be said of every resolution or amendment now reported to the Fellows. Thus the Fellows find themselves supplied with a voting paper which they are supposed to use for the purpose of supporting those candidates who represent their views, and they are expected to record their approval or disapproval in complete ignorance of the acts and opinions of those for whom they vote. We say that such a system is indefensible, that every Councillor should vote under the eye of his constituents, and that it is insulting to the intelligence of those constituents to suppose that they are willing to vote blindly, or upon the faith of the whisperings which they may hear from one or other party.

COLLEGIATE EXPENDITURE.

As to the contents of the Council's Report itself, several points of interest and importance call for notice.

In the past year, 11 candidates were admitted to the Fellowship; 122 the Letters Testimonial; 12 the Diploma in Midwifery; and 11 the Dental Diploma.

Honorary Fellowships were conferred on Dr. T. Crawford, C.B., Director-General, Army Medical Department, and Surgeon-General Sir J. A. Hanbury, M.B., K.C.B.

The total expenditure of the College was £5,642, of which

The Establishment absorbed		£1,417
Including the large sums of £431 for deputations to London, and £125 for the fees on alteration of Charter.		
Salaries and Wages absorbed		574
The Library		434
The Museum		488
The School		308
The Examiners		2,222

Although the income of the College has been rather less than in previous years, the judicious administration of the collegiate funds has resulted in a considerable reduction in the debt which the College incurred for the rebuilding of the school. The Council had determined to charge this expenditure against revenue, rather than make it a permanent incubus on the collegiate funds, and there is a reasonable expectation that within the coming financial year the entire sum will be liquidated.

VOTING BY PAPER.

Much of the report is devoted to the proceedings of the Council in the matter of voting by paper. The recommendation of the Fellows, that the Council should make provision for *absentia* voting was brought down to the Council in due course, and was the subject of much discussion.

The proposal to carry it into effect was met with the objection that the vote of the Fellows had not the necessary force, being come to in an irregular meeting without any notice, and, in fact, by the hasty decision of a few, and not by the deliberate voice of the College; and that, therefore, a plebiscite of the Fellows at large ought to be taken before proceeding to seek a change of Charter for the purpose.

The Report dismisses the anxious debate which ensued in the Council with a bald statement that these suggestions were "declared lost," and that the Council referred the execution of the business to a committee; yet it devotes five pages to the narrative of a squabble between Dr. Brunker and the committee, which is not of sufficient importance to be worth recapitulating.

ALTERATION OF CHARTER.

The alteration of Charter to enable the election of examiners and professors to be effected by a vote of the entire Council, instead of by seven members selected by lot, and, in accordance therewith, the election of Dr. Foot *vice* Dr. Little, as Professor of the Practice of Medicine; of Dr. Frazer in place of Dr. Cunningham, as Professor of Anatomy; of Dr. Stack as Professor of Dentistry; and of the various Courts of Examiners—were carried out. The abrogation of the old, cumbersome, and erratic system has proved a great advantage to the College, and will, we doubt not, tend to ensure the election of the best man for the vacant office, irrespective of the element of chance which frequently vitiated previous elections.

DENTISTRY.

The establishment of a Professorship of Dentistry, the appointment of so distinguished a specialist as Dr. Stack to the chair, and the recognition of the Dublin Dental Hospital as a school of dental instruction for Ireland, are very important steps, not only to the College, but to the dental profession in Ireland. Unhappily the Council has counterbalanced the benefits to education thus secured by continuing the sale of dental diplomas *sine curriculo* to persons who possess no special education, and who are taken from a low

social grade. A number of persons have been admitted to the College who do not pretend to have had any education in dentistry, who stand side by side with barbers, tobacco-nists, and chemists' boys in the Dental Register, and who have been in the habit of advancing their trade by advertising and other disreputable means; and they have been so admitted notwithstanding an explicit undertaking, given to the Medical Council that the College would cease from this traffic.

It behoves the Fellows to see to this matter, and to vindicate the dignity and the credit of their College by putting a stop to this very disreputable traffic. It is certainly not to be expected that the public will honour the L.R.C.S.I. while they see the L.D.S.R.C.S.I. diploma framed and hung out in the nearest chemist's shop.

CONJOINT EXAMINATION.

The educational policy of the College has been centred in a proposal for a voluntary scheme of examination, to be carried out conjointly with the College of Physicians, which, however, has, like former schemes, come to nothing.

The proposition, excellent in itself, though of doubtful expediency as regards the interests of the College, was marred by a totally untenable requirement that the College should refuse its diploma to everyone who had not already satisfied the educational views of the College of Physicians. Such a suggestion was clearly unacceptable, and the more so because it would have excluded from the College the whole of the Licentiate Apothecaries in Ireland, and, in the end, the scheme was wrecked on this shoal, and we feel justified in congratulating the College on the miscarriage of this ill-considered scheme. It is sufficient to say that, at the best, the College was bound to lose £1,100 a year if it had been carried into effect, and that it could not possibly gain a shilling or a shilling's worth of credit by the transaction.

THE MEDICAL BILL.

The only other point in the Report of the Council deserving notice is its proceedings with reference to the Medical Bill. We need not dwell upon this subject further than to say that the policy of neck-or-nothing opposition to medical reform which found expression in a vote of thirty of the Fellows at a scratch meeting called for the purpose, proved—when tried by the test of practicability—to be altogether unworkable. The Council, therefore, saw the wisdom of falling back upon the amendment of the Medical Bill, reserving the policy of opposition for use if the amendments should not be attainable. Nothing has been done further than to urge these amendments upon the Government; but the next month is pregnant with great events, and it will need the utmost astuteness and energy of the coming Council to protect the College if the Bill should, as is expected, go forward. Certain amendments of the Bill ought to be insisted upon, and failing them, the influence of the College must be used to the utmost extent against the measure. But we hope that we have heard the last of the Huxley dogma, the Buccleuch compromise, and all the other forms of side-wind opposition to which a certain number of the Fellows of the College unthinkingly committed themselves. Such dogmas have no support in Parliament, and it would be madness for the College to place dependence in them.

There will probably be a large meeting of the Fellows on May 31st. We venture to hope that they will exercise their right of inquiry and thought to a greater extent than they have done on former occasions, and will not be induced to give

blind personal votes upon subjects of the highest moment to the College and to the profession at large.

Sanitary Department.

SUPPLEMENT TO THE TWELFTH ANNUAL REPORT OF THE LOCAL GOVERNMENT BOARD.

[FIRST NOTICE.]

THIS Supplement contains the medical officer's report to the President and numerous highly valuable appendices, consisting of vaccination returns and statistics, inspectors' reports, and the results of scientific investigation.

Dr. Buchanan first reports that 7 per cent. of the London births in 1880 escaped vaccination, compared to 4½ per cent. elsewhere; this he ascribes to the more movable character of the population of the metropolis. Of the 1,350 vaccination districts inspected during the year 1882, Parliamentary awards were made in 751. Reference is made to the now historical Norwich and Derby vaccination inquiries, where the ill-effects of vaccination were in both cases found to be due to carelessness either of operating or storage and conveyance of lymph. Attention is drawn to Dr. Cory's heroic auto-inoculation with syphilis, which was shown to be caused by purposive neglect of two of the Board's instructions to public vaccinators. At the Board's suggestion, the Foreign Office made inquiry as to the practice of vaccination and prevalence of small-pox in various European countries. Statistics are given as to the supply of humanised and of animal lymph received and distributed by the National Vaccine Establishment. With reference to the latter kind, there seemed to be less difference between it and the humanised as regards success, local and constitutional effect, and influence of storage, than was formerly supposed.

Coming now to local inquiries, Mr. Power's investigations into the outbreak of diphtheria at Purbright are commended for study, being probably connected with the assembling of scholars. The same observer's attempt to trace the incidence of scarlatina in certain London districts beyond mere infected-milk distribution to actual disease of the supplying cow analogous to human scarlatina was made the occasion of experimental research by Dr. Klein, but so far, with no definite result. Dr. Barry's Bangor inquiry eventuated in finding the outbreak of enteric fever to be due to pollution at the filter-beds of the public water supply by specifically infected river water flowing over them. Outbreaks of malignant pustule amongst the Southwark tanners are ascribed by Mr. Spear to contact with Chinese or-hides. Dr. Blaxall's emigration inquiry, which was started in great part by complaints of the American Government as to the introduction of small-pox, is referred to in detail. Whilst duly appreciating the solicitude as to the health of the emigrants by those who direct emigration, Dr. Blaxall points out the want of co-operation between shipping companies and sanitary authorities, and the lack of medical inspection of foreigners landing in this country. Dr. Ballard's diarrhoea inquiry is reported to be still proceeding, and will be looked forward to with very great interest.

The Report of the Royal Commissions on Hospitals is referred to, and mention is made of the acceptance of Mr. Power's facts and inferences regarding the spread of small-pox from the Fulham Hospital. Intimation is given as to the preparation of a revised Memorandum on Infectious Disease Hospitals, and the appended memoranda relating to school-closing are mentioned.

Of the purely scientific investigations, Dr. Klein's experiments with anthrax "vaccin" have proved in the main negative, and those with the artificial "vaccin charbonneux" of M. Pasteur totally so. Dr. Buchanan therefore concludes that Pasteur's products have not the power claimed of causing a modified anthrax, and regrets that the eminent French chemist has not published the details of his method. On the other hand, Dr. Klein confirms Koch's observations as to the limitation of the virulence of bodies dead of anthrax to those which show wounds or have been opened after death. Allusion to Dr. Sanderson's indications as to the line of future researches regarding disinfectants is succeeded by announcement of the beginning of such under the Department's supervision. Dr. Thudichum's investigations into the chemical constitution of the brain are mentioned as affording a new departure in this important and complex subject.

The medical officer concludes his brilliant summary by a reference to the retirement of Mr. Netten Radcliffe, and his former invaluable national services.

(To be continued.)

PUBLIC HEALTH. (a)

THIS recently published handbook, which is intended by its author as a practical guide to the chief sanitary enactments and regulations, supplies a want much felt by health officers and others concerned in sanitary administration, who, as occasion required, have hitherto been obliged either to wade through the Acts and Orders themselves, or trust to the more bulky manuals of Glen and others.

The Public Health Act of 1875 naturally claims the greatest part of the volume, its definitions being expanded and illustrated, its provisions explained by reference to cases, its omissions pointed out, and remedies for defects suggested. Thus, the terms "drain" and "sewer" are more fully defined; the question whether a local authority can insist upon the adoption of the water-carriage system of excreta disposal is discussed, and a decision against such insistence quoted; common lodging-houses are defined, according to the ruling of Sir A. Cockburn and Lord Hatherley, as places where persons of the lower classes, strangers to one another, inhabit one common room, and their keepers as those who derive profit from them. Attention, again, is drawn to the limitation of the notices to be sent by keepers of common lodging-houses regarding cases of fever or other infectious disease to those in bed, it being very properly pointed out that many highly infectious sufferers are not confined to bed. The right of entry for the various purposes of the Act is neatly summarised, and the distinction emphasised between absolute and conditional right. With regard to the penalty attaching to the exposure of unsound fish or meat, it is shown that the exposure of each fish and each piece of meat is a separate offence. Again, it is pointed out with respect to the isolation of infected persons in hospital, that, though no power is given to retain them, yet if the patient leaves the hospital, he can be fined five pounds for wilful exposure by sec. 126. The appointment of officers and tenure of office are explained, and it is shown that the medical officer of health may in his discretion perform the duties of Inspector of Nuisances.

An abstract of several other Acts is given, e.g., Sale of Food and Drugs, Canal Boats, Artisans and Labourers' Dwellings,

(a) Practical Guide to Public Health. By T. W. Hime, A.B., M.B. London: Baillière, Tindall & Cox. 1884.

Alkali, Vaccination, &c., and their chief provisions are epitomised. The Dairies, Cowheds, &c., Order of the Privy Council is given in *extenso*, and a wish reiterated that the Local Government Board should possess the powers of the Privy Council under this Order. A list of the Board's circulars issued between 1875 and 1883 is also furnished, and comprises references to many valuable memoranda, as those on small-pox, vaccination and re-vaccination, sanitary condition of cemeteries, trichinosis, &c. Article 98 of the Education Code, 1882, as to the power to close schools in order to prevent the spread of disease, is quoted. Valuable hints as to the examination of meat, and as to the construction and administration of hospitals for infectious diseases, are afforded. Finally, some useful tables and formulæ are appended, taken in great part from Parkes' treatise, and a carefully-prepared index completes the whole.

Besides its manifest utility to officers of sanitary authorities, we can recommend Dr. Hime's compilation to gentlemen who are preparing for the Cambridge or other sanitary science examinations.

CASCARA SAGRADA.

JUST now this remedy is exciting considerable attention in America, its physiological and clinical effects being closely studied, and its efficacy being highly vaunted by those who have used it. C. W. Tangeman, M.D., Cincinnati, Ohio, has made a series of experiments upon dogs for the purpose of deciding its *modus operandi*, with the following results:—

1. Cascara sagrada, when given in small doses (15 to 20 drops), acts like a vegetable bitter on the stomach; it increases the flow of the gastric juices, stimulates the peptic glands to increased action, thereby bringing about healthy gastric digestion.
2. It acts on the sympathetic nervous system, sending an increased blood supply to the intestines.
3. It increases to a limited extent peristaltic action of the small bowels; but increases it very much in the colon, and especially in the rectum.
4. It has a specific action on the rectum in the way of peristalsis, to cause this portion of the bowel to unload itself.
5. It does not affect the passage of food in the small intestines any more than a bitter tonic would.
6. It is not a safe remedy to prescribe in pregnancy or uterine disorders, especially when given in large doses.
7. It does not affect the larger glandular organs, liver, pancreas, or spleen, even when given in cathartic doses.
8. Hypodermically, the remedy will never produce the permanent good results in chronic constipation that are obtained when it is given by the mouth.
9. When employed subcutaneously, it acts simply as an evacuant to the rectum.
10. The same quantity given hypodermically that produces marked effects when administered by the mouth will not have the same effect clinically or physiologically.

Over-dosage, such as 3j. doses of the fluid extract frequently repeated, is injurious, or to say the least of it, not beneficial.

Given in small doses for some time, the good effects are said to be permanent and pleasant.

It must not be used at random, as a matter of routine prescribing; its proper effect upon the peristaltic action of the bowels must be borne in mind, and it must be used only when it is desired to speed the contents of the bowel on their way. If all that is claimed for it be true, it will prove of special benefit as an evacuant of the colon and rectum.

The effect of simple bitters being to increase the secretion

of mucus, and in the stomach of the gastric juice, and so improve digestion, nutrition, and the evacuation of the bowel contents, we see how cascara sagrada exerts a beneficial effect in this direction also, apart from its purely cathartic properties.

T. L. Wright, M.D., of Bellefontain, Ohio, contributes to the same journal (*Therapeutic Gazette*) an interesting paper with clinical records of its use, in support of the beneficent effects of the drug given in the form of a cordial, prepared by Messrs. Parke, Davis, and Co., of Detroit. For the constipation of weakly and elderly people his experience of its use in from 20 to 30 drop doses, twice or three times a day, has been most favourable. He warns his reader, however, from expecting that the use of the drug will be uniformly satisfactory. There are some constitutions over which it does not seem to exert much control; at the same time, he has never found it injurious in its action to any constitution. Cascara sagrada appears to him peculiarly well adapted to those cases of defective enervation of the alimentary tract depending upon constitutional causes, no matter whether the subject be the aged and worn out, or the young and feeble.

F. C. Herr, M.D., Philadelphia, Pa., Physician to S. W. Hospital, speaks most favourably of its beneficial effects. The importance of having at command a drug which, whilst promoting proper evacuation of the bowels, at the same time improves the general tone of the digestive tract, is such that it is to be hoped some pleasant form for administration may be prepared by our leading druggists, and that "cascara sagrada" may receive a more extended trial in this country, and that the results may be carefully recorded and published for the information of the profession, and, if it is truly all that it is asserted to be, for the benefit of the community at large. Constipation is not one of the easiest of those difficulties with which a medical man has to contend. It frequently taxes his therapeutic resources to the utmost to cope with the discomfort induced. Mental health, and a successful battle for the necessities of life, are but too frequently dependent upon an unloaded rectum, and the reverse, upon the opposite condition. If a man's, or a woman's, bowels remain confined and uncomfortable, the day's tasks have to be faced at a disadvantage, and without that sense of ease and buoyancy necessary to their proper and successful performance.

Before leaving the subject, it may not be out of place to emphasise the well-known fact that the bowels can be educated by a strictly observed habit to act regularly and satisfactorily, and that medical men should encourage their patients to cultivate this habit as far as possible. A fixed time of the day ought to be set apart for a visit to the water-closet, whether the desire for defecation be felt or not. Many who have not hitherto paid attention to this point will be astonished at the results obtained if the habit is steadily persevered in. It is to be hoped that the cascara sagrada will fulfil the expectations formed of it, and that another useful and reliable remedy may be added to the practitioner's *armamentarium*.

Messrs. Parke, Davis, and Co.'s London agents are Messrs. Burgoyne, Burbidges, and Co.

It is currently reported that the Managers of the Metropolitan Asylums District have applied for the consent of the Local Government Board to the erection of a hospital for small-pox patients at Gore Farm Estate, Essex, at a cost of £120,000. If this be true we sincerely trust the Government will refuse to sanction any such outlay, there being sufficient fever hospital accommodation in London to combat any outbreak of small-pox likely to occur.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, MAY 28, 1884.

THE BRITISH MEDICAL ASSOCIATION AND THE MEDICAL BILL.

A GENERAL meeting of the British Medical Association has been convened to assemble this day in compliance with a requisition signed by 53 members, the purpose stated being to consider the Medical Bill and the action of the Journal of the Association in suppressing a large number of letters thereupon.

The requisitionists are clamorous in their asseverations that the Medical Reform Committee has betrayed, and is betraying, the profession by omitting to give earnest consideration to the details of the Bill, or to make any effort to improve away its many faults, and they charge that the Journal of the Association has lent itself to this alleged neglect of duty by systematically concealing from the profession the details of the Bill, and the effects of same, and by suppressing every communication which attempted to elucidate the proposed reform or to criticise its details.

We are very unwilling to take part against those who have in hand the guardianship of the profession in the matter of reform; still less do we desire the task of criticising the act of suppression charged against the Journal editors, but we find it necessary to say that any one who reads the pages of the official organ of the Association must have learned that there is abundant reason for the indignation expressed by the requisitionists. The *animus* of the officials of the Association, and of its editors, is self-conferred by the fact that these 53 members who have ex-

cised their reasonable constitutional right in calling this special meeting of the Association are publicly ridiculed in an editorial note in the current issue of the *British Medical Journal*, their grievances spoken of as "imaginary" and "special to themselves and their friends," and that an underhand attempt has been made to bring the meeting to a *fiasco* by fixing it for Birmingham, where the wire-pullers perfectly well know those who might criticise their acts will not go in sufficient number to outvote the Medical Reform Committee and the supporters of the *Journal* policy. It is plain that those who have adopted this means of checkmating the requisitionists are not desirous that the members of the Association should discuss the bearings of the Medical Bill, and they have, it seems to us—by the way they have treated the requisitionists—pleaded guilty to the indictments preferred against them.

The charges which will be made at this meeting against the Medical Reform Committee must, we suppose, have reference to their omission rather than their commission, because we are not aware that they have done anything whatever. The Medical Bill does not, indeed, bear the mark of the existence of such a body, for, as far as we are informed, it is before the House exactly as it would have been if the committee never existed, and it seems to us that all that the British Medical Association has done throughout its progress has been to cry "Hear! hear!" whenever Ministers wanted a cheer. This is not a very useful function, nor one very creditable to those who consider themselves the mouthpieces of the great British medical public.

The Bill will certainly not be discussed as it ought to be at Birmingham, but, in our opinion, it ought to have been long since fully, widely, and openly debated, both in meetings of the Association and in the columns of its *Journal*, and we are confident that if the members had been given a chance of knowing its contents they would have risen to a unanimous demand for its amendment. We go the full length with the requisitionists in saying that, if the Medical Reform Committee and the editors of the *Journal* pass the Bill as it stands, they will have grossly betrayed the trust which they hold on the part of the profession, and they ought to be made answerable for the betrayal.

PASTEUR'S PROPHYLACTIC FOR RABIES.

ONE of the most noticeable features of the "Reports on Hydrophobia" which appeared in these columns was our insistence on the necessity of further investigations into the nature of this disease, and our hopeful prognostications that as Medicine had triumphed over many other diseases, she would also conquer this scourge of the canine race. The position hitherto had been one of despair. The last word was supposed to have been said. If our reports had no scientific value, they would yet be entitled to some degree of praise for the very element of hope—*dolce speranza*—introduced with them. Pasteur's more recent researches on rabies—even though they may not prove as successful when tested as he hopes—will nevertheless do good: they will lead us a step forward; they will encourage other workers; and, above all, they will inspire the public with confidence and put an end to the unreasoning terror which the very name of hydrophobia always inspires. Hope in

disease has lately been our theme. In no instance is Hope more required or Faith more powerful than in the treatment of many nervous affections left by the bites of dogs or animals.

Pasteur's communication to the Academy of Sciences, Paris, is in every sense a remarkable one. Our attitude will now be one of expectancy, for, however far it may seem, *prima facie*, that he has proved his case, yet another crucial test must be applied before we can proclaim trumpet-tongued to the world—"The remedy has been found; rabies has been conquered." A full account of his researches has not yet come to hand, but from various sources we are able to compile an account of what he has done:—

1st.—He has not found the special microbe on which hydrophobia or rabies depends.

2nd.—He believes that such a microbe exists, and without finding it, he nevertheless conducted some experiments which warrant him in drawing certain conclusions. Amongst the most important are the following:—If the virus of rabies be transmitted from the dog to the monkey, and then from monkey to monkey, it will be found that after each transmission the virulence of the virus has become enfeebled. If the virus thus enfeebled be re-transmitted to a dog or an animal of that species, it will remain still attenuated. By a few transmissions of the virus from monkey to monkey, there can easily be obtained a virus so attenuated as shall never communicate, by hypodermic inoculations, the disease to a dog. Inoculations by trepanning of such virus will likewise produce no result; but an animal will, notwithstanding, be rendered thereby proof against the disease. The virulence of the virus becomes, on the contrary, augmented in its passage from rabbit to rabbit. If a dog be inoculated with virus thus augmented in power, a far more intense form of the disease will be manifested than that apparent in ordinary canine madness, and it will invariably prove fatal.

We must not attribute to Pasteur any more than he himself claims. He does not assert that at present canine madness can be extinguished by vaccination, but he thinks that he has advanced so far that he can prevent any ill effects from the bite of a rabid dog. Experiments are necessary to test his experiences. Pasteur purposes that the following be made:—1. The principal experiment will consist in taking from his kennels twenty dogs insusceptible to the disease, and placing the same in comparison with twenty ordinary dogs. 2. All these forty dogs shall then be bitten by a number of dogs in a rabid state. If the facts enunciated are exact, the twenty dogs that he believes to be proof against the disease will remain healthy, while the other twenty will become affected. 3. For a second experiment no less decisive, he will place before the Commission twenty vaccinated and twenty unvaccinated dogs. 4. All the forty shall then be inoculated in the most sensitive parts with virus taken from a rabid dog. The twenty vaccinated dogs will resist, and the other twenty will all die of madness, either paralytic or furious. These experiments are fair tests. There are certain elements which will have to be considered in connection with them, but we feel certain that in the hands of the men who are on the Commission every point will be minutely examined and all elements of fallacy included. The French Go-

vernment have appointed on the Scientific Commission Dr. Beclard, Dean of the Paris Faculty ; M. Paul Bert, Professor of General Physiology at the Faculty of Sciences ; M. Bouley, Professor of Comparative Pathology at the Museum of Natural History ; Dr. Villemin, Professor of Clinical Surgery at the Military Pharmacy ; Dr. Vulpian, Professor of Comparative and Experimental Pathology at the Paris Faculty of Medicine ; and M. Tisserand, Director of the Agricultural Department. We shall keep our readers *au courant* with the doings of this Commission, and trust that it may be able to verify the accuracy of Pasteur's work.

THE QUESTION OF SUBJECTS FOR DISSECTION AGAIN.

AN important discussion took place at the Bakewell Board of Guardians (Derbyshire) last week, touching the handing over to the Sheffield School of Medicine the unclaimed bodies of vagrant paupers for the purposes of dissection. This question had been before the Board some time ago, and as it affects every part of the United Kingdom, we propose devoting a few remarks thereto. On a former occasion the Bakewell Board decided that unclaimed bodies should be so handed over to the authorities at the Medical School in Sheffield, and for some time past this decision has been adhered to. It was, however, reopened at the last fortnightly meeting by a dissentient guardian; a special attendance of members taking place to consider and vote upon it. After a sharp and prolonged discussion, in which almost every member present took part, the original resolution was affirmed, 26 voting for it and 22 against, three remaining neutral. It is to be hoped that the question is now set at rest. Making every allowance for the good feeling and sentiment of those amongst the guardians who were opposed to the proposal, it is difficult to credit them with a large share of discretion or common sense. It is not in accordance with good sense to shut one's eyes to the absolute (however painful it may be) necessity for an abundant supply of bodies for dissection purposes ; nor is it discreet, in the face of such a necessity, to raise public discussion upon such unpleasant topics, which can serve no useful purpose beyond obtaining for those raising it a spurious popularity with the unreflecting portion of the public, who are taken only by the glitter of the sentiment involved, and who do not follow the bearings of the question upon the other side.

It would, of course, be absurd for us to dwell for one moment upon the advantages to be derived by medical students from a good supply of bodies for dissection, or to mention in detail the benefits that must in the long run result to the public generally, and to the poorer portion of the public especially, by the possession of a sound knowledge of the anatomy of the body by our future surgeons. Such knowledge *can only* be acquired by steady, careful, and long-continued dissection of the body itself. Book knowledge alone is simply useless. The parts must be seen, and handled, and studied in all their manifold relations to the surrounding parts. In the present day, when such immense forward strides have been made in surgery, and when past achievements are but harbingers of future and possibly still greater

triumphs, it is more essential than ever that young surgeons entering upon their professional career should be thoroughly familiar with every part of the human frame, for upon such knowledge must hang the balance of life or death for some poor sufferer whose life is of the highest value to those dependent upon him or her as the case may be. It is a matter for congratulation that in the Bakewell Board of Guardians there is a majority of clear-headed and sensible men, who were not led away by feelings of mere sentiment to do that which would have formed a mischievous precedent for other such bodies throughout the country, and to a certain extent have inflicted an injury upon the profession in increasing the difficulties that are at present experienced, and are already numerous enough, in the effort to secure a sufficient supply of bodies for the purposes of dissection and the teaching of anatomy, only unclaimed bodies being now available. Unknown, of little use to the world or to themselves during life, unwept for, and unmourned in death, their bodies may at least usefully and without profanation serve humanity after death, and so prevent the possibility of resort to the horrors of the olden days, when the exigencies of anatomical instruction made it necessary to rob the newly-made grave, with its attendant harrowing of the hearts of mourning kinsfolk.

We trust the time will come when it will be no longer discretionary with boards of guardians or the governors of public institutions to withhold unclaimed bodies, but that they will of right be at the disposal of the anatomical professors for educational and humanitarian purposes. With our congratulation to the Bakewell Board of Guardians, we would include the teaching body of the Sheffield School of Medicine that the matter has ended in such a satisfactory manner.

Notes on Current Topics.

Society Work and Summer Weather.

It was clearly evidenced at the Clinical Society, on Friday evening, that ordinary frequenters of such meetings feel little disposition to extend their attendance at them beyond the date duly arranged at the beginning of the session. Owing to the fact that a certain number of papers received by the secretaries of the Society remain unread, it was suggested that an extra meeting should be held for the purpose of enabling their authors to communicate them, with a view to their publication in the annual volume of the "Transactions." On being submitted to the meeting, however, the resolution was lost by a vote, the numbers being six for and seven against, the great majority of members present abstaining from an exhibition of interest one way or the other. It must be admitted that arguments against the proposed practice are weightier than those in favour of it ; and not the least of these is the danger of establishing precedent and so leading to an ultimate perpetual extension of the period during which the meetings are held. Last year an extra meeting *was* held, and with anything but an encouraging result as regards the attendance and discussion. The Clinical is a most popular society ; it achieves a large

amount of very valuable work, and it may fairly be conceded that eight months in each year is quite as long as interest in such proceedings as characterise its meetings will be maintained among its members. In weather like that we are now enjoying it is beyond endurance to sit for an hour and a-half in a close room, however well ventilated, under the intellectual strain involved in a due attention to the details of clinical records; and that this opinion is entertained by more than ourselves has been clearly demonstrated by the vote to which reference is made above.

Reform of Procedure at the Clinical Society.

THE President of the Clinical Society, Sir Andrew Clark, Bart., gave notice on Friday evening of certain changes that will be introduced for the first time next winter in the mode of conducting the business of the Society. The most important alteration is that having reference to the exhibition of living specimens, the value of which in an educational sense can scarcely be over-estimated. Much of the benefit that members might derive from examination of the patients so frequently shown at the Society is lost to them, owing to the imperfect and somewhat scrambling manner in which such examinations are of necessity made under existing rules. For the future, however, this section of the work done will acquire a much greater share of prominence, and, in the words of the President, greater publicity will be given to the cases. A second improvement to be instituted at the same time, deals with the provision of tea and coffee, which refreshments, in place of following after, will precede the meetings, an arrangement at once more sociable and more reasonable than that which has previously obtained.

The meeting of Friday last was remarkable for the paucity of discussion on the papers communicated. But four of these were down for reading, and the last having been completed soon after 9.30, nothing remained but to close the session more than twenty minutes earlier than is customary. Under the circumstances it seemed almost ironical to commit the meeting to a vote on the question of holding an extra sitting; and possibly the breakdown on this occasion may have restrained a good many members from declaring in favour of the motion. It is but right to add that for four years at least, such an occurrence has never before been witnessed at the Clinical Society, the rule being rather that some gentlemen are undelivered of speeches at the usual hour for closing; and at one time it was the custom, against which we then urged objections, to prolong the debate for a quarter or half an hour to exhaust discussion.

Varicella and Nephritis.

EARLY in the present year Henoch reported the discovery of albuminuria in four children recovering from chicken-pox, the symptoms developing within one or two weeks after recovery; and in relation with these instances, Dr. G. W. Rachel communicates notes of seven cases of a similar nature to the *Archives of Pediatrics* for April 15. As in Henoch's experience, the children in whom this symptom presented progressed to convalescence, although in one or two instances extreme oedema of the lower extremities and feet and of the face, attended with much suffering, ap-

peared. The conclusion Dr. Rachel appears to feel warranted in drawing from a study of his own cases, and comparison of them with those of the distinguished pediatrician referred to, is that nephritis may be a not uncommon sequela to varicella; and should this be so, it may be right to look on this complaint henceforth as deserving more than the trifling attention it usually receives at present. It is by no means improbable, however, that both Henoch and his American corroborator have chanced to observe special cases, in which individualism has played an important part in determining the nature of effects produced on the body by changes incident to even an extremely mild form of fever. It would be rash to generalise at this stage of the discovery.

Ice Cream Poisoning.

AT this season of the year indulgence in ice cream is so general among all classes of the people, that it is a little startling to learn from our American contemporary, the *Polyclinic*, that poisoning may result from the custom. In the paper referred to Dr. Ewing reports seventeen cases of poisoning among a party of persons who had partaken together of ice-cream and cakes. The symptoms were nausea, violent pain in stomach and abdomen, vomiting, and the passage of thin, liquid, dirty-water-looking stools; cramps in the extremities also existed. All the patients recovered. Analysis of the cream revealed nothing to account for the result, nor was any uncleanness of the cans in which it was made observed. It is suggested that decomposition of the milk or cream had occurred, producing an irritant matter similar to that found in potted meats, which was the poison in these cases.

The Hospitals Association.

LAST Wednesday the Hospitals Association met to receive and discuss a paper by Mr. Burdett, "On Uniting the Hospital Sunday and Saturday Funds," by which he thought they might become more useful to hospitals than as now separately administered. The paper bristled with opinions, but was certainly lacking in facts. The history of the establishment of the Metropolitan Hospital Sunday Fund was not correctly given. We will not, however, go into that part of the question, but rather proceed to consider whether by uniting the two funds any good purpose would be served. In Mr. Burdett's opinion the first step necessary to be taken would be the formation of a general board of management out of the committees of the two funds, and which body should issue all rules and regulations of every kind, a strict compliance with which should entitle hospitals and dispensaries to participate in the collection; the same body should also become a lever for redressing grievances, reforming abuses in hospital management, and bringing about uniformity of system in every case—in short, an *imperium in imperio* in all things. By amalgamation the present lavish cost of collection will be considerably reduced, and a saving effected which would conduce to raise the amount for distribution. At present it appears that the cost of collecting the Hospital Saturday Fund is far greater than that of the Sunday Fund, the cost of the former being 13½ per cent. as against 3½ per cent. of the

latter, and $3\frac{1}{2}$ of the joint sum raised in Liverpool. This at first sight may seem to be high; but when we consider the vast extent of the metropolitan area, the increased cost of living, and the consequent self-denial required for the practice of thrift, and so forth, among the artisan class, it cannot be thought to be a very excessive increase, for without calling paid agency into existence, the collection could scarcely be accomplished. On the other hand, the Hospital Sunday Fund is at little or no cost for collection, and office accommodation for its secretarial work is freely provided at the Mansion House, so that no kind of comparison can be instituted. In our opinion, if the two funds or bodies were united, the contributions of the working classes would gradually dwindle away, whereas the Hospital Saturday Fund has been decidedly, although slowly, on the increase. Again, the two committees could scarcely be expected to blend. The attempt to do so in the early days of the Hospital Sunday Fund was not encouraging. The clergy, the gentleman, and the working men did not get on well together; jealousy sprang up, and the independence of the working man become jeopardised, and the system of doling out hospital letters did not inspire confidence, and never will. There will also be differences of opinion as to the share those who assist to collect the funds should exercise over its management. Working men understand the wants of their class, and should be encouraged to manage their own affairs, even to the distribution of hospital relief. The Hospital Saturday Fund, although under a cloud on its initiation and early management, now enjoys the sympathy and confidence of men like Mr. Fawcett, who have thought out the question in all its bearings, socially and morally; and since the movement seems to be on the high road to success, it is undesirable to disturb it; indeed, nothing of the kind should be attempted unless a much better scheme can be devised than that put forth by Mr. Burdett for uniting the Hospital Sunday and Saturday Funds.

At a largely attended meeting of the supporters of the Hospital Saturday Fund, held in the rooms of the Society of Arts, on Saturday last, Mr. Samuel Morley, M.P., President, who occupied the chair, referring to Mr. Burdett's opinion "that the working expenses of the fund were too great," said the way to meet this was to double the amount of the contributions, for it was only manly and right that all working men should contribute according to their means to institutions from which they derived so much benefit. This advice the working men present pledged themselves to follow, the idea of amalgamating the two funds being regarded with general disfavour.

A MEETING of the Senate of the Royal University of Ireland will be held to-morrow (Thursday, the 29th inst.).

ACCORDING to the last weekly official returns of the mortality in foreign cities, five of these gave a death-rate exceeding the births—viz., Bombay, Geneva, Madras, Rotterdam, and St. Petersburg. London is again to the fore, with the lowest mortality of any of the large cities in the world.

Reuben Harvey Memorial Prize.

NOTICE has been given that the first award of this triennial prize will be made on July 1, 1885. The competition is open to all students of the Dublin schools, and also to graduates or licentiates of Irish licensing bodies of not more than three years' standing at the time of the award. The prize will be awarded to the writer of the best essay, on a subject to be selected by the candidate, evidencing original research in animal physiology or pathology; the essay to be illustrated by drawings or preparations. The essays are to be sent in before June 1, 1885.

Sale of Putrid Meat.

CHARLES HILL, butcher, of Bradford, has been committed to prison by the Bradford magistrates for three months, without the option of a fine, for the above offence. He had exposed for sale in his shop the carcasses of a cow and a calf, the meat of which was certified by the inspectors and medical officers to be totally unfit for food, putrid, and positively injurious to health. We are glad to find the magistrates unprepared to look leniently upon such an offence, than which we can scarcely conceive one more disgusting. Indeed, the only fault we can find with the sentence is, that the term of imprisonment is scarcely long enough, and we are left in doubt as to its being coupled or not with hard labour. Such sentences, however, are steps in the right direction, and we trust they may have the desired effect in putting an end to so dangerous and filthy a practice.

THE opposition of the licensing bodies to the Medical Bill rests chiefly upon the assertion that the person who had passed the State examination would never take a diploma from any College, inasmuch as he could register his name and practise legitimately upon the State examination certificate alone. We find this objection put in such form in a "Statement" just issued by the Irish College of Surgeons, that it is necessary to give a peremptory denial to the figures with which the argument is supported. The College says:—

"The supporters of this Bill argue that the higher class qualifications of the College (its Fellowships) will be more eagerly sought for, and that the College, being entitled to charge what it pleases for these higher titles, will have an opportunity thereby of recouping itself. The simple answer to this argument is to be found in the history of the past. Reference to the Annual Reports of the College will prove that of those who have gained the 'bread-winning' qualification of the College—its lowest title, Licentiate—90 per cent. remained satisfied with it. That this present condition of affairs is not peculiar to the Irish College may be inferred from the fact that 85 per cent. of the *alumni* of the English College of Surgeons remain content with its lowest qualification."

If this statement be intended to mean what it expresses, i.e., that those who receive the L.R.C.S.I. take no other qualification, it is totally inaccurate, for it has been shown that hardly one per cent. of the qualified surgeons are contented to practise on their surgical licence alone. If it is intended to mean that 90 per cent. of the Licentiates of the College do not seek a higher qualification, it would, we believe, be also inaccurate, for very many of them go for higher qualifications in other licensing bodies. If it is intended to mean that the great majority of the Licentiates of

the Irish College do not within the limited period of five years take the Fellowship of that particular College, such a statement proves nothing whatever, and may be dismissed from consideration.

It has been decided to appoint a medical officer of health to look after the sanitary affairs of the garrison at Woolwich, and Brigade-Surgeon T. Rudd, M.D., has been selected as the first to fill the office.

THE Council of Owens College have decided to add to the Medical Department of the College a special department for the study of dental surgery, and advertise for a lecturer in dental surgery, and special lecturers to be appointed annually in dental mechanics and dental metallurgy.

Two hundred and thirty-three candidates presented themselves for the examinations just concluded at the London College of Surgeons, as compared with 220 at the corresponding period of last year. Of this number, 23 were referred to their professional studies for three months, 50 for six months, and two for nine months, making a total of 75 referred candidates.

In the principal foreign cities the rates of mortality per 1,000 of the various populations were, according to the latest official returns, as follow:—Bombay 28, Madras 86, Paris 28, Geneva 28, Brussels 28, Amsterdam 25, Rotterdam 38, The Hague 21, Copenhagen 24, Stockholm 23, Christiania 17, St. Petersburg 45, Berlin 25, Hamburg 25, Dresden 25, Breslau 28, Munich 31, Vienna 33, Prague 33, Buda-Pesth 37, Turin 38, Venice 25, Lisbon 29, New York 24, Brooklyn 20, Philadelphia 19, and Baltimore 19.

THE deaths registered last week in the principal large towns of the United Kingdom corresponded to an annual rate of 21.1 per 1,000 of their aggregate population. The death-rates in the several towns were:—Brighton, Norwich, Sunderland, Wolverhampton 16; Bristol, Huddersfield, Sheffield, Birkenhead 18; Newcastle-on-Tyne, Leicester, Derby, London 19; Salford, Blackburn 20; Preston, Nottingham, Cardiff 21; Hull, Bradford, Birmingham 22; Bolton, Halifax 23; Liverpool, Edinburgh, Glasgow 24; Portsmouth, Leeds 25; Oldham 26; Plymouth, Manchester 27.

THE highest annual death-rates last week in the large towns from diseases of the zymotic class were—From measles, 3.4 in Oldham, 2.8 in Plymouth, 2.7 in Portsmouth, and 2.7 in Wolverhampton; from whooping-cough, 3.4 in Bolton, 2.4 in Huddersfield, 2.2 in Liverpool, and 1.4 in London; and from scarlet fever, 2.2 Cardiff, 1.6 in Sheffield, and 1.1 in Leeds. The 28 deaths from diphtheria included 11 in London, 4 in Portsmouth, 3 each Edinburgh and Leeds, and 2 in Glasgow. Small-pox caused 30 deaths in London (exclusive of 12 registered in the Metropolitan Asylum Hospitals in Dartford sub-district), 5 in Liverpool, 3 in Sheffield, 3 in Hull, and 1 in Sunderland.

A MEDICAL contemporary notices the death of Dr. Richard Sumner, the oldest local medical practitioner, at Formby, near Liverpool, who died recently at the ripe age of eighty-six. His name will always be remembered in connection with one of the most courageous and successful acts ever attempted. On a stormy night in December, 1883, a pilot-boat, containing twenty-two lives, struck on a bank within sight of those on shore, but too far distant for any help to reach them. Even the hardy fishermen feared to put out in it, until Mr. Sumner, who was a man of splendid physique, six feet six inches in height, and of great strength, slung a bottle of rum round his neck, stripped off his clothes, tied a slender line round his body, and plunged into the seething waves. He reached the vessel, poured some rum down the throat of each half-dead man, and so heartened them up that when the boat arrived they were saved from a watery grave. He received the Royal Humane Society's gold medal and every token of esteem to their lives' end from the men whom he had so nobly rescued.

Scotland.

[FROM OUR NORTHERN CORRESPONDENTS.]

HEALTH OF EDINBURGH.—The mortality in Edinburgh for the week ending with Saturday the 17th inst., was 107, and the death-rate 23 per 1,000. Diseases of the chest accounted for at least 60 deaths and zymotic causes for 22, of which 1 was due to fever, 1 to diphtheria, and 1 to scarlatina. The intimations for these diseases for the week being 6, 7, and 22.

DECREASE OF THE SMALL-POX EPIDEMIC IN GLASGOW.—Dr. Russell's last fortnightly report affords evidence of the steady decline in this epidemic, there having been during the fortnight but 10 cases of small-pox registered, as compared with twelve in the preceding fortnight. Of these 8 belong to the eastern district, 1 to the central, and 1 to the western. The cases were all mild, the parties affected having been vaccinated in infancy.

MORTALITY IN GLASGOW.—The deaths in Glasgow for the week ending with Saturday the 17th inst., were at the rate of 28 per 1,000 per annum, as compared with 29 in the previous week, and 38, 27, and 24 in the corresponding periods of 1883, 1882, and 1881 respectively.

UNIVERSITY OF ST. ANDREWS.—BIOLOGICAL LABORATORIES AND EXTENSION OF THE MUSEUM.—The extension of the museum and the procuring of biological laboratories having become urgent, because of the requirements of modern science teaching, the authorities of the University have resolved to approach Government with a view to secure these very desirable objects. More than twenty years ago, Dr. Macintosh, the present Professor of Natural History, drew attention to the exceptionally favoured position of St. Andrews on the sea coast, for founding a biological station, and in the beginning of 1875 the subject was again prominently referred to. Finally, in March, 1883, an effort was made to obtain a portion of a considerable sum of money handed over by the Committee of the Edinburgh Fisheries Exhibition to the Scottish Meteorological Society, with a view to founding such a station at St. Andrews. The authorities of the University of St. Andrews believe that this extension would result in great good to science and the

public; and they feel assured that their efforts will be as warmly supported by all patriotic Scotchmen.

"THE FEAR OF DEATH" AT THE GLASGOW UNIVERSITY.—Last week a melancholy case of suicide occurred on the Wemyss Bay Railway line. The unfortunate man was a medical student, Angus McDonald by name, and a native of Greenock. The pending examination two months hence at the University of Glasgow seems to have preyed upon his mind. He deliberately laid his neck on the line in front of a goods train, and though the driver saw the body in this position he was unable to pull up before the head was completely severed from the trunk.

REMOVAL OF ANDERSON'S COLLEGE WESTWARDS.—We understand that the directors of this College have contributed £5,000 towards the removal of the medical staff of this useful school to a more eligible site, nearer the University, and that the handsome subscription of £500 is besides promised by a gentleman. It is calculated that for £10,000 an efficient habitation for the medical staff can be obtained, and the site most favourably spoken of is the neighbourhood of Partick Road. Any movement tending towards the extinction of the monopoly at present possessed by the Universities must command our warmest sympathy, and we wish the medical staff of Anderson's College all success in their laudable undertaking.

EDINBURGH ROYAL MATERNITY AND SIMPSON MEMORIAL HOSPITAL.—The directors have appointed as assistant physicians to this hospital Dr. Charles E. Underhill and Dr. David Berry Hart.

A NEW PARK FOR EDINBURGH.—Due to the untiring public spirit of Sir George Harrison, the present Lord Provost of Edinburgh, another open space has been provided for the town in the purchase of Blackford Hill, well known to all readers of "Marmion."

"Still on the spot Lord Marmion stayed,
For fairer scene he ne'er surveyed."

Mine own romantic town."

It was the view from this hill that fired Marmion's companion FitzEustace, that—

"to give his rapture vent,
The spur he to his charger lent,
And raised his bridle hand,
And, making demi-volte in air,
Cried, 'Where's the coward that would not dare
To fight for such a land!'"

PUBLIC BATHS FOR EDINBURGH.—Some time ago we drew attention to the fact that Edinburgh did not contain a single public bath where the poor for a few pence could enjoy the luxury of a bath. Manchester, we learn, possesses three public baths, and in London there are between twenty and thirty of these valuable aids to cleanliness and public health. Surely, as the Town Councillors are already the controllers of the water supply, it would not be difficult to provide the necessary buildings. Edinburgh boasts of possessing the oldest medical officer in the kingdom, yet in the five-and-twenty or thirty years that he has held office he has not been able to procure so desirable an addition to the health and comfort of the town. Where is the Health Society? Having supplied an advertisement for all their available friends, surely they might now turn their attention to the practical working out of some of the schemes which have been so ably placed before the public of Edinburgh. Our Scotch friends seem slow to take a hint, but they are intensely annoyed when the hint has to be repeated in somewhat forcible language. We hope that Sir George Harrison will see his way to add yet another sum to the debt of gratitude which Edinburgh already owes him.

KNIGHTHOOD FOR LORD PROVOST HARRISON.—We learn from our contemporary the *Scotsman*, that the Queen has graciously permitted Mr. Gladstone to offer the honour of knighthood to Lord Provost Harrison, and that it has been accepted by him. The honour is, we are sure, enhanced by the manner in which it is conferred. The Lord Provost is offered it "in recognition of special services rendered to the municipality of Edinburgh;" in other words, he is offered it because of good, honest, honourable work done for his fellow-citizens.

CHANGES IN THE EXTRA-MURAL SCHOOL OF MEDICINE, EDINBURGH.—At a meeting of the lecturers on Friday last the vacancy in the Anatomical Department to be caused by the retirement of Mr. Charles W. Cathcart at the close of the summer session was considered, and the lecturers unanimously elected Mr. J. Macdonald Brown, M.B., C.M. Edin., F.R.C.S. (Eng.), and F.R.C.S.E., to the position, who will enter on the duties of the lectureship when the Anatomical Rooms open on the first of October. Mr. Cathcart will for the future lecture on surgery in the Nicholson Square division of the School. Of the original number of lecturers at Minto House only three or four now remain, the rest having found class-rooms in other parts of the town.

Obituary.

WILLIAM JOB COLLINS, M.D.

DR. WILLIAM JOB COLLINS, who died at his residence, Albert Terrace, Regent's Park, London, on May 10th, was born at Oxford in 1818, where his father, Mr. Job Collins, was a well-known veterinary surgeon. He was educated at New College, and was first intended for the Church, but an accident in the hunting field when only eleven years old, and which laid him up for more than a year, turned his aspirations in the direction of the practice of physic. In 1837 he was accordingly apprenticed to Mr. Ward, of Oxford, but it was not long before he decided to quit his native city and betake himself, alone, to the greater world of London, where he continued his apprenticeship under Mr. Fowke, of 6 Berkeley Square. In 1844 he entered University College, then in its palmy days, with Liston, Cooper, and Elliotson as his professors, and with whom by his indomitable energy and originality of character he rapidly became a great favourite. In 1846 he became M.R.C.S., and after a year spent at the Paris hospitals he established himself in Park Street, Regent's Park, in which neighbourhood he carried on an active and increasing practice for 30 years, enjoying a high reputation for his medical skill, and this with the further attractions of his artistic taste and talent, combined with a warm heart and liberal mind, secured him a very extensive acquaintance and many intimate friends. He took the L.M. of the College of Surgeons in 1853, graduated M.D. of King's College, Aberdeen in 1854, and became L.R.C.P. (Edin.) in 1859. In 1852 he married Miss Treacher, a descendant of the old Huguenot family of Garnault, and whose loss in 1830 he bitterly mourned. In 1854, while on a driving tour near Bristol, the horse, a spirited animal, took fright and ran away, and leaping the parapet of a bridge over the Avon, precipitated Dr. Collins and his wife, carriage and all, on the mud-banks of the Avon, breaking his arm and bruising him severely, his wife escaping less damaged. The rare pluck, however, which characterised him was unabated, and henceforth he was one of the prominent followers of Her Majesty's staghounds, and his friend John Leech immortalised him in his sketch in *Punch* of the hunting doctor dressing in the brougham. His great talent for oil-painting, developed relatively late in life, surprised many of his older friends, and the industry and zeal with which he covered the walls of his residence, and the variety of scenes which his pictures portray are amazing, and, *si monumentum queris, circumspice*, is true enough of him. In 1859 he was "hung" in the Royal Academy, and in 1871-72 in the International Exhibition. He was often advised to forsake the stethoscope for the brush as a profession,

but would always reply that he "painted for the love of the thing." In parochial matters, too, Dr. Collins was a leading spirit. Elected at the head of the poll as guardian under the new Act in 1869, he served on the committee for erection of baths and washhouses in St. Pancras, and was also chairman of the building committee of the new St. Pancras Infirmary. In vaccination he was a well-known medical heretic, and was a witness before the Select Committee of 1871. He also published a work, in 1867, entitled, "Have you been Vaccinated, and what Protection is it against the Small-pox?" Although his views were opposed to the great majority of the profession in this matter, his sincerity was always beyond doubt. Dr. Collins was Fellow of many of the learned societies, and his generous liberality and good heart, no less than his jovial face and cheery voice, will be missed by a wide circle of friends.

SIR HY. WENTWORTH ACLAND, K.C.B.

BUT a few weeks ago it was officially announced that Her Majesty the Queen had been advised to bestow a C.B. upon the Regius Professor of Medicine in the University of Oxford, and President of the General Medical Council. It comes therefore upon us as a matter of much surprise to learn that the Sovereign has this week been pleased to bestow the higher dignity of "Knight Commander of the Civil Division of the Order of the Bath, second class," and it will naturally be asked by the curious, What has Dr. Acland done or said since the bestowal of the C.B. a few weeks since, to merit this doubt's favour? We believe the answer will be found in the fact that the recipient was much disappointed with the lower distinction, and this being "influentially" represented in the proper quarter, the K.C.B. was forthwith accorded. No one having the privilege of knowing Dr. Acland will grudge him the coveted distinction, or withhold from the courteous President of the Medical Council their congratulations upon his elevation. The only fault found will be that it was not bestowed earlier, and that the lesser honour was passed in the first instance.

THE MEDICAL BILL

HAVING been brought from the Lords to the Commons on April 4, was, on Wednesday, 21st, suddenly issued to the Members and set down for second reading for the 22nd. Of course it was not seriously expected that it would come on on that evening, because supply was in front of it, but nevertheless the Irish Colleges immediately put their agents in motion to stop further progress. Blocks had, however, been already put on by Mr. Tomlinson, M.P., and Mr. Watson, the insensate obstructionist, who is only known in the House as the Member who objects to everything without caring or knowing what it is.

As the Bill was not read on the 22nd the Government has put it down for Thursday, June 5th, immediately after the reassembling of Parliament, and, what is more significant, has given it the place of first Government order over the heads of the London Government Bill and Irish Sunday Closing Bill, which are their primary measures. This undoubtedly means that it is determined to press the Bill and get it out of the way, and thus the complaisant predictions of those who hoped that it would die a natural or a violent death are proved fallacious. We have still two months remaining of the Parliamentary session; all difficulties, such as the Franchise Bill, and the Egyptian Question, are cleared out of the way of the Ministry, and there is nothing to stop their secondary measures, so that the Medical and other class Bills will surely come on for discussion. Of course the second reading of the Bill will

pass almost without opposition, and it will then remain for those interested to force an amendment of details, which it greatly needs, and which, we have reason to believe, the Government is prepared for. If the Colleges had not been so foolish as to knock their heads against inevitable principles, and if the professional organisations had been awake (which they have not been), the necessary changes of detail might have been already secured. Possibly the Government will now be less willing to listen to remonstrances, but if there be any chance of making the Bill a fair workable, acceptable measure, it will be by accepting the inevitable and asking what is reasonable. If those interested adopt an attitude of mulish opposition, they must endure the penalty of failure.

THE IRISH DRUG CONTRACT SYSTEM.

AT a recent meeting of the North Dublin Guardians, on the occasion of the opening of tenders for the supply of drugs, great differences were found in the proposed prices—one firm tendering for £1,335, and another for £805. On a motion that this last tender should be accepted, it was remarked that the price per gallon put down for spirits of wine was four or five shillings less than distillery price. We have frequently exposed the frauds practised by unscrupulous drug dealers upon innocent and not very careful guardians under the contract system] which is approved by the Irish Local Government Board. The items in the estimate are so priced by the contractor who tenders that those articles which are never used are put down at nominal prices, while those in every-day use are charged most exorbitantly. Thus the tot of the column appears small, but the reality of the payment is enormous.

THE IRISH MEDICAL ASSOCIATION.

THE annual general meeting of the Association will be held on Monday next, the 2nd prox., in the Royal College of Surgeons, Dublin, at 12 noon. Amongst the resolutions which will be considered will be several of which the subject will be:—

1. Poor-law Medical Superannuation, as a matter of right.
2. The Remuneration of Medical Officers of Health for functions performed under the Labourers' (Ireland) Act.
3. The Medical Acts Amendment Bill.
4. Proposed remedies for the Abuses of Dispensary Relief.
5. The Exclusion of Dispensary Medical Officers from the Irish Magistracy.
6. The prospects of legislation on the Notification of Infectious Diseases.

The Council and Officers of the Association will be elected, Dr. Jacob retiring from office as President and Dr. Hemphill, of Clonmel, being probably elected as his successor.

The annual dinner will be held on the same evening in the College, and at the *réunion*, which is always largely attended by the provincial members of the Association, it is expected that the Houses of Parliament and the public institutions will be represented.

Correspondence.

THE COMING ELECTION AT THE ROYAL COLLEGE OF SURGEONS IN IRELAND.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—It has come to my knowledge within the last few days that certain Fellows of the Royal College of Surgeons in Ireland are, for reasons best known to themselves,

making an organised effort to unseat several members of Council at the approaching election on June the 2nd. As I am one of those whom it is sought to remove from the Council, and as, for electioneering purposes, my past actions and present opinions regarding two matters which most agitate the Fellows are being utterly misrepresented, I beg opportunity from you to declare myself.

The two matters I refer to are: 1st. The Medical Acts Amendment Bill, now before Parliament; and 2nd. The question of altering the Charter of the College so as to permit the Fellows to vote *in absentia* by papers at the annual election of the officers and Council.

With regard to the first, I am represented—or misrepresented—as being a ruthless supporter of legislation who is determined by his vote and action to countenance Parliamentary enactments even at the cost of giving a fatal blow to the vitality of his College.

My position with regard to the Bill can be very briefly stated. I have long held—and who has not?—that changes in the method of medical licensing are necessary; that the system of dual diplomas in medicine and surgery should be extinguished; that uniformity of curriculum and examination should exist in the three divisions of the kingdom; and that the public and the profession alike should be protected against the practice of quacks by a governing medical body so constituted as to undertake those duties from which the existing General Medical Council has notoriously shrunk. Holding these views, I have welcomed the prospect of legislation; and believing it to be inevitable, I have deemed it politic to declare in favour of a Bill sure to be carried sooner or later, even though the present one contains much that I object to. As the Bill stands, I take exception to much of it; but I believe that the changes which many persons think desirable are more likely to be obtained by a judicious adhesion to the measure for the sake of the good it contains, while the bad will, I trust, be eliminated in committee should the Bill obtain a second reading. In a word, I apply the old saying about “running one’s head against a stone wall,” and try to preserve the College cranium from the ill-directed efforts of those who would hopelessly fracture it and yet do the wall no harm.

With reference to the question of voting *in absentia*, I hold no very strong opinion either way; but I have, since a meeting of the College made a pronouncement on the subject, always voted in favour of such a change in the Charter as would permit Fellows living at a distance to record their votes by means of letters. I have done this in obedience to the wishes of the provincial Fellows, and so far as I can see will retain my present views; but I think a great deal can be said on both sides of the question, and I am by no means clear that if a full discussion on the subject took place before the College the Fellows might not see reasons for changing their expression of opinion on the matter. For myself, I lean neither to one side nor the other, and have obeyed the wishes expressed by the Fellows; but were I resident in the country I would feel an amount of keen anxiety on the point, as I see great danger of the change in question striking vitally at the power and independence of the provincial Fellows. However, it is mainly a question they are entitled to decide for themselves, and as I am a representative on the Council of every Fellow who honours me with a vote, and am as much a representative of the country as of the town, I will always treat, as I have always treated, the wishes of my constituents with the deepest respect.

But lest this letter should be supposed to be written for the purpose of influencing my election, let me at once disclaim any such intention. It is written to set my past action and present views before the Fellows, and to contradict misrepresentation. I deem it unworthy to make any pledge, and I make none. I will go into the Council untrammelled, and with full power to use my judgment and alter my views if I see reason, or I will not go at all. Let my past conduct influence the votes I obtain, and if that conduct is not satisfactory let me not be elected. By the favour of the Fellows I have sat on the Council for five years and have given an amount of time and labour to the duties of the position which no one can estimate except those who have with equal energy discharged them. The labour of the Council proper represents only a modicum of the work done, that of the committees is even more onerous, and together they make a tax upon time and convenience which can hardly be over-stated.

It is a matter of regret that the Fellows are not furnished with more full details of the transactions of the Council; of the work done, and who does it; of the divisions, and how the votes are given; of the attendances at examinations, and who attends. If this information were afforded to the Fellows, I may without vanity say that such a letter as this need not be written, for our constituents would know who were the members that bore the burthen and heat of the day and who were the persons who allow their private convenience to over-ride their public duties. The mere number of attendances of any particular member at Council or committees fails to show this, for councillors may neglect duties of which no record is published.

I have heard with regret that Dr. Jacob is one of the persons whom it is sought to displace. It is often my lot to differ with him on matters of opinion, but I feel bound to say that no greater blow could be struck at the usefulness and independence of the Council than to remove Dr. Jacob from it. Those only who have sat beside him can thoroughly know his fearless and honest independence, his extraordinary acquaintance with matters of detail and policy, and his great and unsparing capacity for work. It would be nothing short of a calamity to lose his services, and if it be true, as is said, that some provincial Fellows are likely to vote against him, I have to tell them that they will vote against the truest friend they have—one who has spared no labour or ability in their services, and who has done more to improve the position of practitioners in Ireland than any man alive. I cannot conceive a policy so narrow as to wish to limit the Council to persons all of one way of thinking; the friction of opinion is the surest way to right reasoning and successful acting, and in a country that boasts its Third Estate to be the source of its freedom and greatness, in which every intelligent citizen recognises the clash of Party to be the means of an even justice and a powerful government, I cannot follow the logic which would banish a minority and deprive it of all voice.

I am, Sir, yours, &c.,

W. THORNLEY STOKER.

16 Harcourt Street, Dublin,
24th May, 1884.

Literary Notes and Gossip.

AMONG new editions of well-known books in preparation are the two classical works of Murchison on Fevers and on the Liver; Carter’s “Medicine;” a fresh edition of Holmes’s “Principles and Practice of Surgery;” a third edition of Claude Bernard’s “Text-Book of Operative Surgery,” by Mr. A. T. Norton; a third edition of Masse’s “Text-Book of Anatomical Plates,” by Messrs. Bellamy and Cantlie; and a second edition of Heath’s “Course of Operative Surgery.”

RINGER’S “Therapeutics” is again, we hear, out of print. This work has had a marvellous success, edition after edition succeeding each other. Martindale’s “Extra Pharmacopœia” has also run through a second edition in less than twelve months. A third edition of Harris and Power’s “Manual for the Physiological Laboratory” has rapidly succeeded the second; and new editions of Keetley’s “Index of Surgery” and Wertz’s “Diseases of Infancy and Childhood” have been demanded.

DR. F. W. SMITH has brought out (Lewis) a neat illustrated brochure on the “Leamington Waters, chemically, therapeutically, and clinically considered.” These useful saline waters have been too much neglected, and the pleasant town of Leamington offers English comforts and many advantages which foreign spas cannot give to English invalids who are not accustomed to Continental ways. We shall be glad if our British spas come more into favour.

A SERIES of popular papers, twelve in number, on Prevention of Disease, by Dr. Cornelius B. Fox, have just been issued as a pamphlet by Messrs. Churchill, and will be found serviceable in the way of suggestion to lecturers and others, as well as for the information of the general public on several matters relating to personal and domestic hygiene.

DR. EDGAR G. BARNES has brought out a handy little work, entitled, "How to Arrest Infectious Diseases." The author gives some useful information and hints as to the comparative value of the various disinfectants, and on the precautions necessary during convalescence from infectious diseases. He refers to the danger—to others—of sending away convalescents before all danger of infection has passed away, and lays down as a maxim that "he who is not safe to mix with the members of his own household is not safe to travel or to go into lodgings."

ON Wednesday last Dr. A. Tucker Wise read before the Royal Meteorological Society, a series of observations taken in the Maloja (Engadine) during the winter 1883-84. The paper was the result of a very considerable amount of attention and careful observation of the weather—state of the atmosphere, temperature, rain, and snow-fall, &c., during the period referred to. The Maloja is as yet a comparatively unknown winter resort for invalids, but its beautiful situation and equable climate will ensure for it a near future, the credit of which will in no small measure be due to the earnest advocacy of Dr. Wise.

IN this country it has not yet become the fashion to engage physicians on the staff of newspapers as an inducement for readers to purchase. Our Parisian neighbours have, however, hit upon the expedient, and *Le Petit Caporal* announces that it has engaged "two eminent physicians," who after the first of next month will give advice gratis to those who take in the paper. We have a quack American dispensary in London, which advertises advice by post by eminent members of the profession, but like the French journal it does not mention names. We fear this "eminent" adjective will soon have to give way to another part of speech—at least, so far as medicine is concerned.

THE republication by Dr. Morell Mackenzie, in pamphlet form, of his lecture on "Hay Fever," which was delivered at the London Hospital, is very opportune, as it will enable those who may during the hay season come across sufferers from this distressing malady to obtain the latest views thereon; not, by-the-way, that any very original propositions are or can be urged after the issue of that model book (Blackley) on the subject; indeed, Dr. Mackenzie has founded his remarks almost mainly on Blackley's researches, which is without doubt the classical treatise on hay fever in any language. Still, Dr. Mackenzie's less pretentious summary is not without interest.

IN these days of cheap literature probably nothing has been attempted that can compare with the issue by Messrs. Goodall, Backhouse & Co., of Leeds, of Dickens's works at three-halfpence each. "Sketches by Boz," Dickens's first work, in unabridged form, is the first of the series offered to the public at this nominal figure. It is true the type is small and the paper not of the finest quality; but when one considers the quantity of paper required to produce a work of this extent in demy 8vo, apart from the cost of composition and printing, one cannot help thinking that philanthropy must for once have been combined with commercial enterprise for the benefit of the masses, by the spreading of healthful literature.

THE translation of MM. Cornil et Ranvier's profound treatise on Pathological Histology, which was undertaken by Mrs. Hart, is progressing, and this week we have received volume II, part I, "Lesions of the Organs." In its English dress the work will be considerably larger than in the original French, but to those unable to read it in that language the translation will be a decided boon. Part II of Southam's "Regional Surgery" has also made its appearance, together with vol. I of Barnes's "System of Obstetric Medicine;" and among other new books which have made a bid for favour during the present month may be especially mentioned Dr. MacNaughton Jones's "Practical Manual of Diseases of Women;" Dr. Hime's "Manual for Health Officers;" Dr. Bruce's "Materia Medica;" and a "Manual of Diseases of the Ear," by Dr. Barr.

DR. A. McLANE HAMILTON has published (New York and London, Bermingham and Co.) a small manual of medical

jurisprudence. It is offered as an "elementary treatise and a book of reference for lawyers and doctors." It may be useful to them, but we should suppose that even lawyers would look for something less limited. The author only deals with the nervous system, and then only such of its conditions as are the subjects of litigation. For such purposes English doctors and lawyers will naturally prefer an English book. For students the book is, of course, too limited in its scope. This is the first volume of "Bermingham's Medical Library" in cheap form we have seen, and we cannot say much for the get-up, the paper and illustrations being of a very inferior description to that we are accustomed to in this country.

AN enterprising physician in London, whose name we are not permitted to breathe, thinks the profession is not sufficiently well supplied with literature; he has therefore resolved to fill the void with another weekly journal, under the title of the *British Medical Advertiser*. The coming light is not yet, we believe, fully developed; but we have caught a glimpse of its title-page of nearly the dimensions of the *Times* newspaper, on which was printed "This journal is forwarded post free to every registered medical and surgical practitioner in the United Kingdom. No. 1, vol. 1. Thursday, May 15." How very considerate of the physician to supply the wants of the entire profession all the year round for nothing. He has our hearty thanks for his public spirit and surpassing philanthropy. This also the profession at large will doubtless accord when May 15 arrives; but there is always a delay with the first number of a journal, and we crave for the enterprise, patience.

MR. KENNETH MILLICAN's work on "The Evolution of Morbid Germs" is necessarily theoretical in character. Mr. Millican believes that the germs of the various infectious fevers are not necessarily separated from one another by hard and fast lines. He thinks that in the course of successive generations they may become much modified. A strong point in favour of Mr. Millican's views is to be found in a perusal of the records of such anomalous cases as one he reports, in which there were symptoms of enteric, typhus, diphtheria, and small-pox simultaneously. In this case, the author remarks that, but for the astounding nature of the assertion, one would have been tempted to say that the patient was suffering from all four diseases simultaneously. He would explain such cases by the theory that morbid germs become modified in successive generations in accordance with the laws of evolution. The work before us certainly contains numerous facts which would seem to support this view.

THE Grocer's Company announced, some time ago, that it was their intention to found several scholarships for promoting original research among English scientific men, and also to award at the end of three years a special prize of £1,000 to the person solving a particular problem to be set by a special committee of examiners. It will be remembered that the question proposed for solution in the first instance is that of discovering and cultivating the virus of small-pox according to the Pasteurian method, Drs. Buchanan and Burdon-Sanderson, together with Prof. Tyndall and Mr. Simon, being the committee appointed to determine the prize. This, however, will not take place until 1886; but on Wednesday last, at a meeting of the Court of Directors of the Grocers' Company, research scholarships were awarded to the following:—1. W. North (renewal), aetiology of ague. 2. Leonard C. Woodbridge, D.Sc., M.B., hæmorrhagic disease, pernicious anæmia, and blood-clotting. 3. Alfred Lingard, M.R.C.S., intimate aetiology of enteric fever.

MR. CORDY JEAFFRESON continues his pleasant chats about "Doctors out of Practice" in the June number of the *Leisure Hour*. His last chapter has perhaps not the same interest as some of the preceding ones, and in its literary character much fault may be found for its lack of continuity and cohesiveness. Still, "Ensigns and Impostures" will be read with interest by those who like to compare the refined quackery in the profession of the present day with the more robust and open charlatanism of the phlebotomists and bone-setters' era. Speaking of bleeding, our author is of the opinion that the title was given to our contemporary the *Lancet* when, in the early part of this century, the bleeding mania was at its highest, and that the journal is an interesting survival of an obsolete medical practice.

IN a pamphlet of 60 pages, "The Crystalline Lens, and the Modes of Examining It," which is in part a reprint of an article in the *Archiv für Augenheilkunde*, and in part a history of the subject, the author, Dr. Robinski, of Berlin, states his objections to the methods in general use, and recommends the employment of a weak solution of common salt for showing the lamellar structure of the lens. After describing various methods of examination, that by coagulation, which he calls the physical method, and that by extraction of water by means of sugar, sugar syrup, and solution of salt, he claims that the last-named gives the best results. For the purpose of showing the intimate structure of the lenticular tubes—or, as some call them, fibres—he intimates his preference for a weak solution of nitrate of silver. By this method, he says, we are in a position to examine fresh preparations at once, from freshly-killed animals, without macerating them for days and weeks, to prove the existence of the membrane of the lenticular tubes, and to obtain a nearer and the most complete insight into the structural relations of this tissue.

"THE Nanheim Springs and Baths" is a reprint in German, in pamphlet form, from the *Berliner Klinische Wochenschrift*, and gives a description of the springs and baths of Nanheim, and of the salts with which the water is impregnated, and pleads for their employment in suitable cases of disease. Nanheim is a small town or village in Ober-Hessen, which has long been celebrated for its thermal and other springs, many of which are rich in salts (lime, iron, manganese, and zinc) and carbonic acid. The underground pressure is so great that in the case of one spring, the Friedrich Wilhelm-Sprudel, the water is forced to a height of fifty-six feet above the bore opening. The baths are recommended for some—especially the later—stages of treatment of articular rheumatism, cardiac affections, scrofula, exudation of all kinds, various diseases of the nervous system and of the sexual organs. For more explicit information we refer our readers to the brochure itself, which will well repay perusal.

The Obstetric Gazette (Cincinnati) is a periodical little known in this country, but, if we may judge of the last number before us, it is evidently doing good work. The number contains two original articles, one on "Posterior Section of the Uterine Cervix in a Virgin for Dysmenorrhœa, followed by Serious Nervous Symptoms, relieved by Trachelorrhaphy," by Thad. A. Reamy, M.D., Cincinnati, an article which is a curious commentary on the treatment of some female affections, and which suggested the question, Would not the patient have been better if left alone?—and one on "Chronic Nasal Catarrh in Children," by H. Allen, M.D. The remainder is mainly devoted to reports of societies, and contains amongst others a report of a valuable paper by Gaillard Thomas, on the "Prevention and Treatment of Puerperal Fever," and of the discussion which followed and which was participated in by Fordyce Barker and others. It is certainly a convenience to those who cannot afford the time to wade through the literature of the day to have a journal at hand which affords them information of all that is going on in the particular department of medicine to which they have specially devoted themselves.

"THE Different Aspects of Family Phthisis in Relation especially to Heredity and Life Assurance," by Reginald E. Thompson M.D. (London: Smith, Elder & Co.), is a neat volume, which will prove of interest to a considerable number of medical men. The evidence on which the author bases his opinions is derived from the records of the Brompton Hospital, and he has had the help of Mr. Bowser in the chapter on Life Assurance. The cases extend over a quarter of a century, and their collation must have cost no little labour. The general result is that family phthisis is in numerous cases the result of hereditary transmission, and that these cases are subservient to stern, unflinching laws. The recognition of this, and the practical application of our knowledge, should lead to some diminution of the disease. In this direction there is perhaps more hope than in the treatment of inherited phthisis by means of drugs, in which our author seems to have slight confidence, though perhaps we may make progress in this direction also.

WHAT has become of our abolishing friend "Society Total Suppression Vivisection," as he delights to be known? He and his few devoted fellow-zealots appear to have undergone somewhat of the process to which they so fiercely condemn "inhuman" vivisectioners. We should, however, be sorry to lose Mr. Jesse altogether from the field of controversy, for it is only justice to have to admit that, should the anti-vivisection party lose his services, every vestige of vigour, and every trace of humour would desert the cause. It may of course be that Mr. Jesse has at length been converted to reason by the masterly series of pamphlets on the vivisection question which have been issued under the direction of the Association for the Advancement of Medicine by Research; and should this be the case it will be no less pleasing than natural, for Mr. Jesse probably does what few of his followers pretend to do even, viz., strive to comprehend something of the subject he attacks. It is, of course, his misfortune to have been led into error on almost every occasion that he has struggled against the odds science brings against him; but tilting at windmills may, under some circumstances, become at once heroic and instructive.

DR. G. GORE, F.R.S., is the author of the Research Advance Association's latest publication, the subject of the essay being "The Utility and Morality of Vivisection." Mr. Jesse will do well to study this pamphlet with a perseverance equivalent to that he has previously shown in forcing his statements down the throats of gullible societarians, and especially that part of it which relates to his rock of refuge, Sir Wm. Ferguson. Dr. Gore clearly explains how this eminent surgeon's opinion on the employment of experiments on living animals could carry no sort of weight, Sir William having never been at any time competent to discuss the question, because of his ignorance of the requirements of physiology as an experimental science. Dr. Gore adds: "Also of the thirteen medical men whose 'medical testimony against vivisection' has been widely published by 'The London Anti-vivisection Society,' the name of only one appears as having published any physiological experiments, and that one has publicly stated that the results of his experiments were 'untrustworthy,' and amongst all the names of the persons who have taken a prominent part in opposing physiological experiments upon animals in this country, I have been unable to find that of a single individual of acknowledged eminence as a scientific experimentalist."

IT is only very recently that a pro-vivisection literature at all worthy of being considered a *bond fide* defence of scientific claims has been opposed to the flood of sentiment and rubbish poured out by "The Society for the Abolition of Vivisection," *et hoc genus omne*. Now, however, numerous able and irrefutable essays are accessible to the public, and have done an incalculable amount of good in exposing the shallow bigotry of the bestiarists, as Prof. Owen has proved them to be rightly called. Among the latest of these, a well-written and closely-reasoned pamphlet entitled "Vivisection in its Scientific, Moral, and Religious Aspects," by Mr. E. D. Girdlestone, B.A., well deserves most honourable mention. It is careful, moderate, and convincing in its statements, and contains a variety of illustrations and arguments, mainly non-technical in nature, which may be very profitably read and studied by "the other side." If these good people, so ready to throw their money to the dogs for their salvation from imaginary tortures, would but devote it to the purchase of sound instruction in the elements of science and good taste, they would not only advantage themselves, but incalculably relieve the world by desisting thenceforth from the mistaken mission on which they are now embarked. By degrees, but slowly, the sort of delusion they are encouraging is becoming plain to their senses, and, at the same time as this is progressing, a bitter lamentation is arising from the agitation-mongers, who have so long waxed rich on the contributions of their supporters. May this continue to be; but meanwhile, Mr. Girdlestone and others like him are doing excellent service to science and reason by writing and publishing such clear and comprehensive proofs of the unreality of latter-day sentiment towards the brutes.

"Medical Fashions in the 19th Century," by Edward T. T.bbitts, M.D. (Lewis), is an amusing little book, in which the author describes some of the variations of medical opinion,

more particularly those which he has had an opportunity of observing during the last quarter of a century. The notes on alcohol, hydropathy, mesmerism, large doses, small doses, bleeding, and many other things, are set in an amusing and perhaps also instructive series of antitheses. The rise and fall of similar mineral waters with diverse names, and of health resorts of most opposite characters, is stated with grim humour. The way in which sewer gas is sometimes alleged to be the cause of numerous diseases, and at others forgotten, is again ascribed to fashion. Dr. Tibbitts does not accept the germ theory, and so favours us with a chapter on bacteriomania, in which he tells us that of all the theories which have prevailed during the present century in the scientific world, he considers the germ theory of disease with all its ramifications as being the most fascinating as well as the most fashionable. He remarks that it is more than probable that in no other department of science is there so much fashion as in medicine, but he admits that for the most part medical fashions have some scientific foundation. This, at first confined within reasonable limits, gradually leads to an immensely inflated reputation, and then degenerates into what can only be described as fashionable. He reminds us, also, how many so-called novelties in the medical world resemble other fashions, inasmuch as they are simply revivals of old remedies or ideas, though perhaps in some disguise. He remarks that "in many, not all, of the medical fashions there is much intrinsic good before they arrive at the 'fashionable' stage, but when once they create anything like infatuation (whether in the matter of treatment or causation) it is highly probable that their beneficial influence is fast on the wane." We do not pretend to endorse all Dr. Tibbitts tells us, though there are many things with which we agree, and a perusal of his book we cordially commend.

NEW BOOKS AND NEW EDITIONS.—The following have been received for review since the publication of our last monthly list (April 30th):—A Manual of Diseases of Women and Uterine Therapeutics, by H. MacNaughton Jones, M.D. The Elements of Physiological and Pathological Chemistry, by T. Cranston Charles, M.D. The Diseases of Infancy and Childhood, by Charles West, M.D. (7th edit.) The Utility and Morality of Vivisection, by G. Gore, F.R.S. Albumen and Sugar-Testing, by George Johnson, M.D., F.R.S. The Guild of Good Life, by B. W. Richardson, M.D., F.R.S. Students' Guide to Systematic Botany, by Robert Bentley, F.L.S. Regional Surgery (part II), by F. A. Southam, F.R.C.S. Seize Années de Pratique Médicale à Contre-réville, par le Dr. Debout D'Estrees. Materia Medica and Therapeutics, by J. Mitchell Bruce, M.D. The Discussion on Albuminuria at the Glasgow Pathological Society. Transactions of the Obstetrical Society of London, vol. XXV. Herschell's Urethral Charts. Disease Prevention, by Cornelius B. Fox, M.D., F.R.C.P. Manual of Diseases of the Ear, by Thomas Barr, M.D. Handy Guide to Public Health, by T. W. Hime, B.A., M.B. The Hip and its Diseases, by V. P. Gibney, M.D. Surgical Emergencies, by Dr. Von Lesser, translated by F. A. Lyons, M.D. A Manual of Medical Jurisprudence, by A. McLane Hamilton, M.D. Excessive Venery, Masturbation, and Continence, by J. W. Howe, M.D. The Leamington Waters, by F. W. Smith, M.D. Confessions of an English Hashish-Eater. Manual of Pathological Histology, by Cornill and Ranvier, translated by A. M. Hart (vol. II, part I). Hay Fever, by Morell Mackenzie, M.D.

Medical News.

Royal College of Surgeons of England.—It appears that the total number of candidates admitted to the primary examination in anatomy and physiology for the Membership of this College during the months of April and May was 581, of whom 179 failed. For the primary Fellowship examination, which is now going on, there are 97 candidates. The following are the examination questions set in anatomy and physiology at this latter examination, which commenced on Friday last:—*Anatomy*: 1. Give the dissection required to expose the complete dome of the pleura of the right side. 2. Describe the action of the muscles passing between the trunk and upper limb in reference to the movements of the shoulder-girdle and arm upon the trunk. 3. Describe fully the 12th dorsal vertebra, mentioning the various structures

attached to it. 4. Describe the dissection required to expose the transversus pedis musculus.—*Physiology*: 1. What are the distinctive functional and structural characters of animal and vegetable cells? Give the evidence on which your statements rest. 2. Describe the means by which a muscle-curve is obtained. What circumstances modify the contraction of muscle and the form of the muscle-curve? 3. Assuming the right forearm to have been voluntarily flexed, describe the course of the nerve impulse by which this movement was excited, from the cerebral motor ganglion cells to its exit from the cord. Give the evidence on which your answer is based. 4. Describe the mechanisms by which accommodation is accomplished, and the methods of accurately determining them. At least three of the four questions must be answered in each section.

Royal College of Surgeons in Ireland.—At a meeting of the Court of Examiners, held on the 21st April and following days, the under-named gentlemen passed the first half of their examination for the Letters Testimonial of the College, viz.:—

George W. Armstrong, Henry Breen, Edward G. Browne, Theodore D. Browne, William G. Chute, Thomas Codd, John J. A. Costello, Robert G. Christy, Cecil Cronin, John Cuthbert, Patrick J. Curtin, William Dunne, John J. Davoren, Vesey H. W. Davoren, Andrew A. Doyle, Alexander T. Drake, John Erropon, Fitzwilliam Evans, Martin, Fennelly, Henry J. Flanagan, William F. Fullen, John J. Gaynor, George E. Green, Henry C. Groves, Ignatius Purcell Hartford, Michael St. Lawrence Harford, Edward Heard, John Hobbs, George E. Hughes, David Humphreys, Gerard B. Irvine, John Keane, Cornelius J. Kelly, Timothy R. Kelleen, Michael B. Kennedy, Henry Knaggs, Francis Blake Knox, John E. Langan, Richard R. Leeper, Reginald T. A. Levinge, William H. Lugger, Anthony J. Luther, Robert F. M'Arde, John B. M'Bride, John D. Macdonough, Daniel M'Cann, John J. M'Donnell, Thomas J. M'Grath, Eirington F. L. M'Kay, Matthew J. Marmion, John J. Moore, Michael J. Moran, Herbert C. Mooney, Bernard Murray, Paul A. Piel, James E. Riddell, John Rogers, Alfred Rows, James L. Kowlette, William G. Rutherford, John J. Savage, John Sellars, Hugh Smyth, Joseph E. J. Soden, Graves Stoker, Henry Stoker, Robert C. Thacker, Malcolm E. Thomson, Hamilton J. Thornbury, Hugh Whelan, and John Whyte. Thirty-six were stopped.

At a meeting of the Court of Examiners, held on the 8th May and following days, the under-named gentlemen passed their final examination for the Letters Testimonial of the College, and having taken the declaration and signed the roll, were admitted licentiates, viz.:—

Berkeley J. Acheson, George H. Bagot, Louis A. F. Bate, John Bernal, Francis L. Carte, James V. Collins, Cecil Cronin, Thomas Crow, Alexander Cuffe, Thomas J. Daly, Julius Barry Delaney, Thomas L. Dillon, Cuthbert Eccles, Patrick J. Ford, Frederick J. Greig, James Hanna, Denis Kennedy, Graham Kennedy, Charles R. Kikelly, Benjamin Lane, Frederick D. Lawson, John Lowney, Edward M'Nulty, Thomas J. M'Grath, James H. Maguire, Edward L. Minchin, Cornelius B. Moloney, Walter A. Murray, Llewellyn T. M. Nash, Charles J. Perrott, William W. Scott, Edward N. Smart, Alexander Stewart, Malcolm E. Thomson, Augustus M. Westropp, Henry E. F. Wright, Thomas N. Wright, John H. Woods, and John F. Yates, Esquires. Thirteen were stopped.

Liebig's Extract of Meat Company.—The annual report just issued affords not only evidence of the enormous and increasing sale of this company's extract of meat, but also of its continued excellence in manufacture. When Liebig, some twenty years ago, introduced his formula, he could scarcely have conceived the extent to which the result of his investigations would have reached; yet here we have a commercial enterprise founded on his theory now declaring a dividend of 12½ per cent. on the extraordinary capital of half a million sterling, with an annual sale of £165,000 in produce. For much of this success the hearty response of the medical profession to Liebig's appeal is probably due, for as an article of invalid diet it at once obtained favour, and prepared the way for those many other extracts, good or bad, which the success of the original preparation prompted.

British Medical Temperance Association, Irish Branch.—The following officers have been elected for the new Irish Branch for 1884-85:—President: Deputy Surgeon-General Gunn. Council—*Dublin Members*: J. Graham Burne, M.R.C.S.E., Alex. E. Carte, M.B., O'Connell J. Delahoyde, M.R.Q.C.P.I., R. Henry, M.B., S. M. Thompson, L.R.C.S.I., James W. Young, M.D. *Country Members*: Ringrose Atkins, M.D., J. W. Boyce, M.B., John Eustace, M.D., Robert Morton, F.R.C.S.I., J. A. Scott, L.R.C.S.I., Brice Smyth, M.B. Hon. Sec. and Treasurer: E. MacDowall Coegrave, M.D., 24 Gardiners Place, Dublin.

Notices to Correspondents.

Correspondents requiring a reply in this column are particularly requested to send their communications to the Editor.

ularly requested to make use of a *distinctive signature or initials*, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

LOCAL REPORTS AND NEWS.—Correspondents desirous of drawing attention to these are requested kindly to mark the newspapers when sending them to the Editor.

READING CASES.—Cloth board cases, gilt-lettered, containing 26 strings for holding each volume of the *Medical Press and Circular*, may now be had at either office of this Journal, price 2s. 6d. These cases will be found very useful to keep each weekly number intact, clean, and flat after it has passed through the post.

WHAT IS A MEDICAL ADVERTISEMENT?—The correspondence on this subject is unavoidably crowded out of the present number.

SALIVATION.

To the Editor of the MEDICAL PRESS AND CIRCULAR.

SIR,—I have a patient, a female, about 30, suffering from constant salivation and exfoliation of the proboscis. She is perfectly healthy in every other respect. The saliva runs continuously night and day, crusts form on the proboscis of both lips, and peel off, leaving the surface tender, but not abraded. There is no swelling or tenderness in the salivary glands; the gums are congested, but not tender. I need not trouble or occupy your space with the multifarious alteratives, tonics, astringents, &c. I have tried, externally and internally, without the slightest benefit, and write this in hope that some of your numerous readers may have had a similar case, and would kindly give me the result of their experience through the columns of your valuable journal. She has been suffering thus for three years; no syphilitic trace whatever.

Yours, &c.,
MYOSOTIS.

May 21, 1884.

PATIENTS WANTED.

VERY HONOURED COLLEAGUE.—I am glad to inform you I became a consulting physician at La Bourboule (Puy-de-Dôme) several years ago, and in such a capacity I solicit from your kindness to address me the patients to whom you advise this thermal station.

So many diseases derive benefit from the use of these waters—scrofula, anemia, skin diseases, herpetic symptoms of the organs of respiration, rheumatism, diabetes, &c., &c.—that it is easy to find a patient to advise them.

I will feel grateful for whatever you do to my advantage, and promise to pay you £1 ls. for every patient coming under treatment through your medium.

Believe me, very honoured Colleague,

Very sincerely yours,

E. DAUZAT, M.D.,
Consulting Physician.

La Bourboule (Puy-de-Dôme),
May, 1884.

[Honesty evidently survives abroad, notwithstanding that its loss is so frequently bewailed on this side of the Channel. The above, from Continental physician, may be of interest to such of our readers as have not been favoured with a copy; it was addressed to one of our subscribers, who appreciates its bearing on recent medico-ethical discussions. Dr. Dauzat evidently thinks human nature controls professional honour elsewhere than in his own narrow sphere.—ED.]

M. S. BUTLER (Brompton).—It is impossible, without a perusal of the MS., to determine whether the paper is or is not suitable; but from your description we doubt that we could use it.

R. K. L.—Notice of the occurrence has not yet been forwarded to us. Possibly you have been correctly informed, as, should anything of so important a nature have been submitted to consideration, it is not likely that the result would continue unknown for any length of time.

DR. F.—Our attention had been already called to the article you mention. It is characterised by the utmost ignorance of the meaning of the clauses of the Act, and in due time we shall undertake to expose the absurdity of the statements it contains. Many thanks for your kindness.

THE COUNCIL OF THE ROYAL COLLEGE OF SURGEONS OF ENGLAND AND REFORM.

To the Editor of the MEDICAL PRESS AND CIRCULAR.

SIR,—It is quite impossible that the controversy between the Council and the great body of the Fellows can remain where it is. As the mover of the resolutions which were carried at the late meeting, and which have been so ignominiously ignored by the Council, I feel bound to take further action. I propose, therefore, at once to place myself in communication with the Fellows, in order that some united action may be decided upon.

I am, Sir, yours, &c.,
PAUL SWAIN, F.R.C.S.

MR. CARTWRIGHT.—Perhaps the case would not have attracted attention were it not that it had been sponsored by an eminent authority on the class of diseases of which it is an instance. The defence urged by apologists for the course that has been pursued is lamentably weak, but it would excite an unnecessary degree of controversy to open up the question of treatment at the present time.

DR. EDWARDS.—We do not see any immediate prospect of such a change as you have advocated; nor are we as yet convinced that it would be altogether desirable to change the rules by which the proceedings in question are now regulated. There is something to be said on both sides; you, however, discuss the matter from a single point of view only, and that to some extent prejudiced.

MR. SAMUELSON.—We cannot depart from the conditions already laid down for the regulation of every such case.

DR. FRODSHAM.—Nothing further has been settled since the meeting took place.

NITRO-GLYCERINE AS A MEDICINAL AGENT.

To the Editor of the MEDICAL PRESS AND CIRCULAR.

SIR,—It appears explosive compounds used by the dynamitards are really converted to better use by some of my profession; and I confess they are a novelty to me as such. The late assistant chief clerk of the Marylebone Board of Guardians, who died suddenly a fortnight since of angina pectoris, whilst under my care, consulted me and others medically many months since, but his case was one too precarious to promise much benefit from orthodox treatment. Some few weeks ago the gentleman in question said he had been advised to a course of treatment which would possibly astonish me, and under such he expressed an immense relief from spasms of the heart. I was shown a box of small lozenges, one or two to be taken frequently when pain came on, and marked Nitro-Glycerine Lozenges, 116th part of a grain in each lozenge, made by a West End chemist near Manchester Square. I confess my ignorance of this "remedy." Might it not be cumulative, and on a sudden shock produce death by explosion? At all events, let the orthodox profession know all about this medical discovery, and oblige,

Yours truly,
J. McGRIGOR CROFT, M.D.,
Medical Guardian of St. Marylebone.

St. John's Wood,
May 24, 1884.

DR. WALLACE (Parsonstown).—Your reply to Dr. Madden "On the Increase in Lunacy" shall appear in our next.

MR. J. A. HUTCHINSON and MR. C. POPE WALKER (Newcastle).—We intend referring editorially to the subject in our next, and will at same time publish the correspondence.

Vacancies.

Birmingham and Midland Free Hospital for Children.—Acting Physician. Applications to the Medical Committee by June 4.
Denbighshire Infirmary, Denbigh.—House Surgeon. Salary £85, with board and residence. Applications to the Secretary by June 5.
Flintshire Dispensary.—House Surgeon. Salary, £100, with furnished house, &c. Applications to the Secretary by June 11.
Glamorgan and Monmouthshire Infirmary and Dispensary, Cardiff.—House Surgeon. Salary, £100, with board, &c. Applications to the Committee by May 31.
Queen's College, Birmingham.—Professorship of Anatomy. Stipend is £262 10s. Applications to the Secretary by June 30.
Sunderland Infirmary.—A Senior House Surgeon. Salary, £100, with board and residence. Applications to the Chairman of the Medical Board by June 2.
The General Hospital, Birmingham.—Resident Assistant Surgical Officer. Salary, £70, with board and residence. Applications to the House Governor by May 31.

Appointments

GRAHAM, G. H., M.R.C.S., L.R.C.P., Medical Officer to the Workhouse and No. 2 District of the Thakeham Union, Sussex.
McNAUGHT, F. J., L.R.C.S.I., L.M., L.K.Q.C.P.I., M.B., Medical Officer to No. 6 District of the Stow Union.
PESKETT, A. T., M.R.C.S., House Physician to the London Hospital.
SINCLAIR, J., L.R.C.P. Lond., M.R.C.S., Clinical Assistant to the Medical Out-Patient Department of the London Hospital.
UTTHOFF, J. C., M.D. Lond., F.R.C.S. Eng., Assistant Surgeon to the Sussex County Hospital.
WILLIAMSON, R. F., M.B., C.M. Edin., Medical Officer to the Langwathby District of the Penrith Union.

Births.

BOOKLESS.—May 21, at 28 Wimbledon Hill Road, the wife of J. Etesaln Bookless, M.D., of a daughter.
HUGO.—May 21, at New Brompton, Kent, the wife of E. H. Hugo, L.R.C.P. Ed., of a daughter.
WILKIN.—May 21, at The Warren, Beckenham Park, Kent, the wife of J. F. Wilkin, M.D., of a son.

Marriages.

BOWMAN—THOMSON.—May 21, at St. Stephen's, Hammermith, Richard Bowman, L.R.C.P., to Florence Julia Alice, widow of James Cameron Thomson, of Penang.
CAMPBELL—MOSS.—May 22, at the Registry Office, Kensington, by licence, William Frederick Campbell, L.R.C.P. Ed., to Julia, youngest child of the late Saul Moss, formerly of Kingston, Jamaica.

Deaths.

ATKINSON.—May 16, at Richmond, Yorkshire, Richard Atkinson, M.R.C.S., L.S.A. Lond., aged 84.
DAVID.—May 18, at 16 Sydenham Villas, Cheltenham, John David, M.D., late of Swansea, Glamorganshire, aged 67.
EBDEN.—at Haughley, William Edden, L.S.A. Lond., Deputy Coroner for Suffolk, aged 69.
PARRISH.—May 10, at his residence, Wordsley, near Stourbridge, John Jones Parrish, aged 59.
SMITH.—May 1, at Ambleside, George Francis Kirby Smith, F.R.C.S., of Northampton, aged 87.
SPENCER.—May 13, at Whitchurch, Bucks, Charles Spencer, M.R.C.S., L.S.A. Lond., aged 73.

ON

THE EYE: ITS DISEASES, AND THEIR REMEDIES.

Being an Abstract of a Course delivered in the Royal College of Surgeons in Ireland,

By ARCHIBALD H. JACOB, M.D. Dub., F.R.C.S.I., Professor of Ophthalmic and Aural Surgery in the College; Ophthalmic Surgeon to the House of Industry Hospitals.

(Continued from page 277.)

Corneal Opacities.

THE result of loss of corneal substance, whether arising from the breaking out of an intra-corneal abscess or from ulceration (herpetic, serpiginous, or indolent), or from a mechanical injury, or scald, will be—

- Cicatrisation, with more or less loss of transparency of the corneal structure, and possibly accompanied by
- Perforation of the anterior chamber, permitting escape of the aqueous humour and consequent prolapse of the iris.

The excessive proliferation of the corneal corpuscles and their fatty degeneration, which are the essence of inflammation of the structure, result in a change of the inter-cellular substance which assumes a fibrous character. If this alteration be great the new structure is opaque; if slight the new structure may be more or less transparent.

Therefore, speaking generally, the amount of opacity left by an ulcer depends on its depth. In its central deepest portion the new structure is entirely fibrous and dense, while, in its margins, the corneal substance is altered only by the proliferation of the corpuscles, and, when the new matter is resolved, these portions re-assume their transparency.

For these reasons, the herpetic and serpiginous ulcers, and the abscesses of cornea, always leave the thickest and whitest opacities, while the indolent, strumous ulcers of

the surface layers, and the abrasions which are caused by injury and heal by first intention, commonly produce no worse result than a cloudiness, which wears off in a few months.

The prognosis of a corneal ulcer, therefore, depends on its depth and the intensity of the keratitis, so that while the surgeon must, in cases of abscess, deep pustule, or excavated ulcer, warn the patient of the probability of more or less subsequent loss of sight and disfigurement, he may, in the case of the milder, shallower ulcers, promise ultimate recovery without much dimness or apparent opacity. In these latter cases it is wise to give warning to the patient that dimness of vision will increase with the healing of the ulcer, according as the abrasion fills up with semi-opaque fibrous material, for without such warning he may suppose that his case is getting worse.

Corneal cicatricial opacities were named by the older writers according to their extent and whiteness—the thinnest little fleck of opacity being called a *nebula* (mist); the same if more dense a *nubes* (cloud); if circumscribed and very dense white, a *margarita*, or pearl; if covering a material part of the cornea, an *albugo*, or leucoma (*λευκος*, white); if involving the greater part of the corneal structure, a *staphyloma* (*σταφυλη*, a grape). Modern writers generally confine themselves to the two latter terms.

The ultimate importance of a corneal opacity depends upon four factors:—

1. Its density.
2. Its position on the cornea.
3. Whether there is much distortion of corneal curves.
4. Whether the ulcer has perforated the corneal chamber.

I have said that the prognosis as to resorption of the opacity depends on the depth of the precedent ulcer. The injury done by the loss of transparency depends upon its position on the cornea. If it be placed near the margin (as is usual in cases of herpetic ulceration), and if it does not perforate, vision is but slightly interfered with, and the injury to personal appearance may be remedied in great measure by operative means. If, on the contrary, the ulcer has been central or nearly so, it

may almost entirely annihilate vision, and produce such deformity as to render desirable the removal of the globe and substitution of an artificial eye. Intermediate positions, in which the opacity covers the pupil, but leaves a sufficient space of transparent cornea, may be in great measure remedied by displacing the pupil, so that the light may be admitted through the transparent structure. If the ulceration has been deep and extensive the cornea is so much thinned and weakened that it yields, more or less, to the posterior pressure within the eye, and thus the

Fig. 22. Staphyloma Cornea.

cicatrised surface comes to be much bulged or altered in shape. In this condition it acts injuriously in two ways—*first*, by projecting between the lids, and thereby suffering friction and consequent chronic irritation; *second*, by altering the curves of the portion of cornea which remains clear, and thus causing the image of external objects to be impressed on the retina in a distorted form, producing an effect akin to astigmatism.

The posterior elastic lamina with its Keratocele and epithelial layer (membrane of Dexomet) *Hernia Iridis*. resists the ulcerative process to a very remarkable degree, because of its structureless character, and the absence of corneal corpuscles in its substance. When, therefore, the cornea proper becomes thinned down, the elastic lamina is pushed forward to occupy the vacancy, and when cicatrization takes place, bulging remains, formed by a very thin stratum of cicatricial substance backed by the posterior lamina. This condition is illustrated at *b* in the illustration. In circumscribed but deep

Fig. 23. Staphyloma and Keratocele (STELWAG).

ulcers it often happens that the entire cornea proper is eaten through, but the erosion there stops, leaving the posterior lamina perfectly translucent, and of a brilliant black colour, blocking the bottom of the ulcer and preventing escape of the aqueous humour as shown in the illustration. This condition is called *keratocele* (κερας, cornea; κυλη, a bag), and it ought not to be mistaken for the hernia of iris, which I shall next describe. As long

Fig. 24. Keratocele.

as the posterior lamina is imperforate, cicatrization of the cornea may take place without displacement of iris or lens, and it is therefore important that the nature of the prolapse should be recognised at once, and the eye guarded from pressure or any other influence which might cause the membrane to give way.

If the posterior elastic lamina does give way and the

aqueous escapes, a displacement of the iris and lens is almost inevitable. At once the posterior pressure on the eyeball causes the iris to fall forward on the back of the cornea, and it blocks the perforation, presenting its free surface to the external air, and often protruding so far as to be subjected to the rubbing of the lids. If the perfora-

Fig. 25. Hernia Iridis.

tion be close to the corneal margin the iris will be prolapsed near its periphery, and the pupillary margin and lens will not be displaced very much from their normal position; but if the opening approach the centre of the cornea the dislocation is much more considerable and the loss of vision proportionately great. In these latter cases the pupil is drawn into an irregular shape, and often is converted into a mere slit, while the lens takes part in the deformity and is tilted more or less obliquely towards the corneal opening.

These *hernia iridis* received a variety of fanciful names, derived from their size and shape. The smallest prolapse, which presents the appearance of a little black vesicle, is called *myocephalon*, from its supposed resemblance to a fly's head. A larger hernia goes by the name of *clavus*, from its similarity in appearance to the head of a nail.

When the greater part of the cornea is destroyed the entire iris is forced by the pressure of aqueous humour into the opening, but being usually bound here and there by bands of lymph to the lens, it presents a black surface irregularly puckered, as shown in the illustration, from which it was named by Beer *Staphyloma racemosum*. It

Fig. 26. Staphyloma Racemosum (BEER).

Fig. 27. Sectional view of same (STELWAG).

is, however, quite possible that the corneal perforation may be so minute as only to permit the aqueous to trickle gently out, and in such case the iris is applied against the back of the cornea, but it is not protruded through it. When so placed a local centre of inflammation of the iris is set up, lymph is poured out, and adhesion is formed between its surface and the posterior cornea, the iris being thus permanently fixed in a false position. This condition is called *synechia*, and the adhesion to the cornea is named *synechia anterior* as distinguished from *synechia posterior* in which the adhesion is between iris and lens. In rare cases the adhesion between iris and cornea is so slight that when the ulcer has healed, the aqueous chamber filled up, and the iris recovered its muscular power, it has sufficient strength to detach itself from the cornea, and it resumes its normal position

leaving a little patch of black pigment on the posterior cornea as the mark of the synechia.

Treatment of Corneal Opacities.—Treatment of these conditions has four objects: *a.* To obtain resorption of such portions of the opacity as are caused by interstitial deposits; *b.* To mitigate the injury to personal appearance; *c.* To restore vision by producing a pupillary opening behind the transparent portion of the cornea; *d.* To restore the eyeball to its normal size whenever a prominent staphyloma exists. For all these objects save the obtaining of resorption, operative measures are necessary, and to obtain resorption therapeutic or local treatment is of scarcely any avail. The only sort of opacity which is ever absorbed is the parenchymatous form in which there is no new cicatricial formation, but only a proliferation of the corneal corpuscles and an infiltration, thereby, of the healthy corneal structure. This condition exists in every case in the marginal part of the ulcer and the greater the extent of the parenchymatous infiltration proportionately to the cicatrizing surface the greater the chance of a clearing up of the opacity. In the case of shallow, non-inflammatory ulcers, the loss of substance may be repaired by corneal structure which, if not normal, is at least sufficiently diaphanous not to interfere seriously with vision and a nearly perfect recovery may, therefore, be obtained. This is especially the case in children in whom the cornea exhibits a reparative power which seldom is observed in the adult, probably because in the natural growth of the cornea the cicatricial fibres are replaced by new transparent normal corneal structure. Therefore it may be taken as an axiom that opacity from parenchymatous infiltration can be helped to resolve and will resolve itself in process of time if left alone, but that cicatricial opacity cannot be influenced by any line of treatment and will not resume its transparency by any lapse of time.

To assist resorption a certain amount of local irritation of the opacity seems essential; at least, all remedies which are at all effectual are slightly excitant; but severe irritants are neither useful nor safe. The dusting of calomel on the opaque surface seems to do good, and is certainly useful if any unhealed ulceration remains. The local application of iodine by collyrium is also apparently of some benefit, and some years ago finely powdered sulphate of soda was much vaunted as a resorbent, but it did not fulfil the promises of its advocates. On the whole, I think nothing approaches in efficacy Pagenstecker's ointment of yellow oxide of mercury already recommended in chronic conjunctivitis. It certainly clears up the ocular surface effectually, but much of the improvement may be due to the restoration of the conjunctiva to a healthy condition.

As internal treatment, to help the possibilities by stimulating the absorbent system, small doses of iodide of potassium or iodide of iron given frequently during the day and continued for weeks or months is orthodox, but I am not satisfied that it produces much useful result. The removal of corneal cicatrices by therapeutic means is—in our present state of knowledge—impossible, and any pretence of doing so is as rank quackery as cancer-curing.

The practice of excising or scraping off corneal opacities and trusting to the filling up of the abraded surface with less opaque tissue was advocated warmly some years ago, but it is not now counted amongst legitimate surgical procedures. It may be resorted to when the opaque portion of cornea is thick and protrudes inconveniently, and where the patient is in excellent constitutional condition, in which case it may be hoped that a smooth, semi-transparent opacity will replace a thick, rough, prominent one, and something will have been gained. It is also applicable in the opacities which arise from the deposit of lead chloride in a healed-up corneal ulcer—to which I shall presently refer—but it is open to the danger of setting up a corneal abscess, or even a panophthalmitis, in either of which cases the patient will be much worse than before. If the excision of an opacity be

undertaken, it should be shaved off with a very sharp cataract knife, taking care not to go with the incision beyond the margin of the opacity, lest it may be enlarged rather than diminished, and not to attempt anything if the opacity is thick and deep. In preference to shaving off, some operators approve of scraping, and devote many sittings to the process, but such a method does not recommend itself as a means of removing *leucomata*, whatever its value may be in producing and extending them.

Transplantation of cornea from the rabbit to the human eye, or from a human eye which has been excised for some disease not involving the cornea, has been recently brought prominently under notice by Dr. Wolfe, of Glasgow, who quotes Dr. Sellerbeck, of Berlin, as the first explicit writer on the subject.

As far back as 1839, the Medical Faculty of Munich offered a prize for the best work on the subject, but without result, until Mr. Power, of London, published a case in which he had successfully transplanted a cornea which he had kept in a solution of common salt. Mr. Wolfe points out that replacement of the entire cornea is an impossibility, by reason of the impossibility of preventing the lens and vitreous escaping when the diseased cornea is excised. To meet this difficulty, Sellerbeck removed a circular piece with a trephine, but Dr. Wolfe prefers inserting a narrow horizontal strip of the new cornea. He describes the operation as follows:—"The patient being put under chloroform, a broad band is removed a little below the horizontal median on each side of the cornea. A lance with a stop introduced into the anterior chamber at the margin of the cornea as far as the globe will allow it to penetrate, and this is repeated at the opposite side. A small probe-pointed corneal knife is then introduced into the anterior chamber, its edge is turned towards the cornea, and made to cut upwards, one section of the cornea being thus completed. In doing this the anterior surface of the cornea must be supported slightly by a flat silver spatula, so as to prevent tearing of the cornea or displacement of the deep structures. To remove the other end of the corneal flap we seize it gently with the forceps, and either cut straight down upon it with a cataract knife or introduce very sharp, flat, straight, probe-pointed scissors, and so divide it. The eyelids are then closed gently until the graft is ready. To obtain the graft we put the patient from whom it is to be taken under chloroform, and dissect a broad flap of the ocular conjunctiva from each side of the cornea, over which the flaps are turned. The eyeball is then enucleated and the lance introduced into the anterior chamber, and the requisite cornea and two conjunctival bands carefully removed and placed in position, being secured by stitches in the corners of the flaps."

Dr. Wolfe gives a successful case, but the value of this operation has yet to be tested.

(To be continued.)

ON STRANGULATED HERNIA AND ITS COMPLICATIONS. (a)

By WM. BERRY, M.R.C.S. Eng. & L.R.C.P. & S. Ed.,
Honorary Medical Officer, Royal Albert Edward Infirmary, Wigan.

MR. PRESIDENT AND GENTLEMEN,—There is perhaps no emergency in the broad domain of surgery, or even in any branch practised by the general practitioner, which requires so much precision in diagnosis, decision in treatment, and skill in operative measures, as strangulated hernia, more especially if one or more complications be present.

When a strangulated hernia is met with in conjunction with orchitis, or hydrocele of the cord, it is not always easy to be certain of the diagnosis, and the delay caused thereby may be fatal to the unfortunate patient. Diagnosis in cases of strangulated hernia requires to be

(a) Paper read before the Wigan Medical Society.

made from (1) inflamed irreducible hernia; (2) obstructive irreducible hernia; (3) general peritonitis conjointly with hernia; (4) double hernia; (5) early pregnancy or threatened miscarriage may obscure the diagnosis (*vide* Erichsen's "Science and Art of Surgery"). The notes of the two cases I wish to relate to you are widely different in their nature and in their result, and from both useful lessons may be learnt.

In the first case we have first, orchitis, with the usual symptoms, viz., pain, swelling, and redness, and after exertion we have increased pain, swelling along the cord, and vomiting for some days. I determined to operate when the symptoms appeared urgent; but the patient rapidly sank after the operation; the gut was found strangulated at the external ring, and was beyond recovery, so much so that it was found necessary to form an artificial anus. I will not detain you longer, but will give you the notes of the first case as reported by our then junior house-surgeon, Dr. Jackson.

A. K., æt. 26, a music-hall singer and dancer, was admitted to the Royal Albert Edward Infirmary, Wigan, on March 10th, 1883. Five days previously, when doing a "hand-spring," he felt a pain shoot into his right groin, and soon afterwards commenced vomiting, and was compelled to take to his bed. From this time up to his admission the vomiting had continued, and there had been no passage of fæces through the bowels, in spite of enemata and other means adopted by the medical man whom he had called in.

On inspection, the patient, a sallow, wiry, but somewhat care-worn looking man, was found to have orchitis of the right testicle, and gonorrhœa. On the prepuce there was a perfectly circular cicatrix, the result of a recent chancre, and in the left groin there was a scar from a recent bubo. On the tongue and mucous membrane of the mouth there were numerous small ulcerations, probably syphilitic, and by the side of the inflamed cord of the right testicle was an inguinal hernia. The patient said that he believed when young he had been slightly ruptured on that side, but had not noticed anything peculiar for years.

Immediately after his admission, chloroform was administered and taxis in the direction of the canal employed, but it was unsuccessful. A consultation was then arranged for that evening, and in the meantime, after a castor-oil enema had been fruitlessly employed, ice was administered by the mouth, beef-tea with liq. pancreaticus and liq. pepticus by the rectum, and the foot of the bed was raised. The temperature was normal; pulse 80, firm and regular.

The members of the staff present at the evening consultation decided that, taking into consideration the possibility of the orchitis pressing on a congenital hernia and thus setting up symptoms of strangulation of the intestine, no interference was called for. A one-grain opium pill was ordered every two hours, with hot fomentations to the inflamed testicle and a poultice over the abdomen.

11th.—Vomiting at frequent intervals. No fæcal odour in vomited matter. Other symptoms the same. Opium discontinued for a time.

12th.—Orchitis subsiding. Other symptoms, including vomiting, the same. To have three ounces of whiskey per diem.

13th.—Vomiting still persistent and thought to have a slightly fæcal smell. Inflamed testicle much smaller, but a dusky appearance over inguinal canal, disappearing on pressure, and thought to be due to the formation of pus.

14th.—Testicle nearly normal in size. Evident formation of pus over inguinal canal. Gurgling, on pressure, from inguinal canal to bottom of scrotum. Vomited matter had a slightly fæcal odour. In the evening the temperature, which had been normal up to now, rose to 100·2.

15th.—Temperature 97·6. Vomited matter decidedly fæcal; and patient showing signs of failing strength.

It was decided to operate at 4 p.m. At 4 p.m., the patient being under the influence of chloroform, the usual incision for operation on strangulated inguinal hernia was made. This allowed an escape of pus with a distinct fæcal odour. The incision was enlarged to allow the cavity to be thoroughly cleansed, and a piece of collapsed gangrenous intestine was found. As this was ruptured and utterly beyond recovery, the constriction was cut through, more intestine drawn through the opening, and the whole of the gangrenous portion excised by two clear incisions. The two open extremities were then stitched to the sides of the external wound in the hope of forming a fæcal sinus and subsequently covering it over with skin and allowing the fæces to pass from one portion of the intestine to the other. The patient was put back to bed, $\frac{1}{2}$ -grain of morphia given hypodermically, heat applied to the extremities, brandy administered, and a poultice applied over the wound. He never rallied, and died at 8.40 p.m.

Although almost moribund, the patient stood the chloroform, which was administered on a simple piece of lint, particularly well. Although the vomiting was persistent, yet it was not so incessant as we see often in cases of acute strangulation. Often he would retain a good portion of the fluid taken, and be a couple of hours before rejecting this back again.

It should also be noted that there was some peritonitis, especially at the lower portion of the abdomen, and this was treated with poultices and opium. At one period during the treatment he seemed to have passed some fæces with the enema that had been administered, and the subsidence of the orchitis caused such an improvement in his general appearance that operative measures were further delayed.

Against the advice commonly given in text-books, it was thought better when operating, considering the state of the bowel, to remove the gangrenous portion and stitch the edge of the bowel to the lips of the wound. Perhaps, however, there would have been less shock if, after finding the state of matters in the inguinal canal, to have left it alone, and allowed Nature to remove the remaining portion of gut.

There is one important point, however, which I want to point out, and which, if adhered to in this case, might have produced a different result, and it is this: That when in doubt, *operate*; or, as ovariologists would say, *explore*.

The absence of stercoraceous vomiting for so long a time, the orchitis and cellulitis along the spermatic cord, with the supposed passage of some fæces, caused me to delay the operation, and this no doubt gave our patient a much less chance of recovering. Mr. Erichsen says, at page 451 of his work on Surgery: "There are few surgeons who will not at once acknowledge the truth of the remark of the late Hey, of Leeds, that he had often regretted performing this operation too late, but never having done it too early."

The other case which I will shortly relate to you is equally interesting. I was called in consultation, on April 5th, to Mrs. H., æt. 42, married, no children. She had suffered from femoral hernia of the right side for several years, and had had it strangulated two or three times, but it was always relieved by taxis; the truss allowed a portion of the tumour to escape below the pad, so that she did not pay much attention to a little swelling of the part. On April 2nd, three days previously, the rupture, after some slight exertion, came down suddenly, and gave her great pain. She sent for her medical attendant, who at once tried to reduce it. Vomiting set in, and she had great pain in the abdomen, but no tenderness. When I saw her on the 5th, we found her still in great pain, vomiting everything she took almost immediately; a small motion had passed the day before, but no relief to symptoms. There was a swelling the size of a cricket ball just below Poupart's ligament; tongue furred; pulse 90; temperature normal. The

vomited matter was of sour odour, but not faecal. Taxis failed. She refused operative measures. On the 6th we met again, and found matters much the same. She had opium in grain doses, but without relief; vomited matter much more fermented looking. She now consented to the operation. Chloroform was administered, and taxis again tried, but without avail. I then operated in the usual manner, and before opening the sac, found the stricture was at Gimbernat's ligament. I divided this, but the bowel refused to return. I now opened the sac, and found the band still constricted the gut, which did not appear much congested. After free division of the band, the bowel still refused to return, I now enlarged the incision, and sought for the cause, and found a number of old adhesions, which I broke down with my fingers. The parts were sponged, and all bleeding stopped; then with some little difficulty the bowel was returned. Two silver-wire sutures joined the lips of the wound, and a pad of absorbent wool was applied. Opium was given, and small quantities of fluid nourishment. Temperature remained normal, and the wound healed by first intention, and in ten days she was convalescent.

Here again we had strangulation for four days without urgent symptoms, and the operation removed beyond doubt the correctness of the diagnosis.

CONSUMPTION VIEWED IN RELATION TO EVOLUTION AND MOLECULAR ENERGY.

By WILLIAM H. PEARSE, M.D.,

Senior Physician to the Plymouth Public Dispensary.

(Continued from page 490.)

Anæmia.—In slowly progressive cases a paleness comes on and remains, not so blanched as in chlorosis. Seeing that in such slow cases the vital power is almost equal to the evolution of healthy growth, I have not dared to seek to alter the seeming almost-equilibrium of "energy" to structure by active means, such as iron, but rather to treat them by a judicious hygiene, in what relates to food, warmth, air, sun-exposure, &c., &c. "Affirmative instances" are the "broad road to destruction" of all safe conclusions, but I can recall a terribly rapid case of phthisis, following the free use of iron, and where a *statu quo* moderate health had existed for years previously.

Amenorrhœa.—I have noted eighty-one of the pre- and phthisical with amenorrhœa; about thirty of these were in actual phthisis. There is a class with complete or nearly complete amenorrhœa for years, and yet who do not pass into lung disease; also the numerous class, who say that they have had scant menses or amenorrhœa for years prior to the lung disease. I had hoped to be able to differentiate these two classes in some essential point of causation, but no general or potential determining causes have appeared. Another class in advanced phthisis have complete amenorrhœa, but also remain, as to the lungs, in *statu quo* for years even. That some phthisical patients have full menses does not lessen the profound correlation of amenorrhœa, and its nerve-centre involvements to phthisis. I do not mean that, if a case present the type of chlorosis—a lumpy, sluggish girl—that iron should be withheld, but I do not dare to prescribe iron in amenorrhœa in "delicate" girls, of phthisical, functional, or physical type. I conceive that the amenorrhœa is part of the great "form" of defective innervation and "energy." I carefully avoid any "special" treatment of this subjective symptom, but direct the patient to quiet, moderate, but persistent general means, such as all and any food she can take and which she finds to agree, duly apportioned out-of-door life, warmth, cod-liver oil, malt extract, &c. I often see cases amongst the poor in advanced phthisis with complete amenorrhœa, and who run along for years doing their duties. I should never dream of giving such cases courses of iron, &c.; I should avoid all that would alter the equilibrium of function and

"energy," except by the most general, natural, and slow means.

But in all this variety of structure and function, which form parts of the true "form" of phthisis, and throughout which a true "continuity" is so paramount, may we not hope to see (a) the "commanding instance" (b) which shall put us in exacter method for arresting the progress of the series into actual phthisis. What determines the potential "energy" which holds our patient with amenorrhœa in moderate health for years? It can only be that some small but potential mode of matter saves such a case from passing into phthisis, as so many others of the same type do. I cannot rest for causes in any range less ultimate than in differences of molecular "energy" in the two classes. Must not our hope be in this direction?

Menorrhagia was rarely spoken of.

Leucorrhœa was not much complained of. I have received the impression that it is not especially excessive in phthisical and pre-phthisical cases. *Costiveness* is common, but this is so usual a state with women in the miserably artificial and indoor-life of the age, that it is not possible to say whether it be specially a symptom of the phthisical. Young people in phthisis have occasionally spoken as having early suffered from other neuroses, such as headache, both frontal and occipital, palpitation, low fever, varied local sweatings, &c.—symptoms equally common to the non-phthisical. But in striving for a new and wide view of generalisation in relation to phthisis, no associated phenomenon should be overlooked. The early class of neuroses and symptoms common to phthisis and to varied other diseases have especial interest, in that we not only see an early approximative unity, but at such early stages we have greater likelihood of perceiving the occasions or causes of the divergence in those who do pass into phthisis.

Hæmoptysis existed in about fifty cases. I have been struck with the great number who have had slight hæmoptysis, even years prior to applying for advice, and in whom no decided physical signs could be detected. I have seen but one case of acute tuberculosis of the lungs; two phthisical cases have died of tubercular meningitis. A considerable number of cases present in whom *wasting* is the chief symptom; often there is no discoverable disease in the lungs. On the other hand, I often see cases of decided phthisis in which the body is not wasted, the arms and infra-clavicular regions being well covered with fat. Patients who walk miles in the country, and whose lungs are in advanced phthisis, will say that they feel much better, and feel quite well! There seems to be an absolute correlation between the beautiful sweetness and contentment of mind of the phthisical and the deficient creative "energy" for the evolution of enduring cell-growth in the lungs. One case only, and that a pre-phthisical, showed the hereditary syphilitic teeth. Two cases from the Mediterranean showed phthisis in association with enlarged liver; two spoke of former rheumatism; one dated his phthisis to West Indian fever. I have only three noted, and those pre-phthisical, with markedly enlarged cervical glands; there were doubtless more, but the two conditions of enlarged glands and phthisis are not commonly co-existent. Two were associated with epilepsy, and two with chorea; in two phthisis followed small-pox; two after measles; one after Singapore fever; eight pre-phthisical cases and one phthi-

(a) "Oh! for a glance into the earth,
To see below the dark foundations
Life's embryo seeds before their birth,
And Nature's silent operations!"—Goethe's "Faust."

(b) Bacon ("Novum Organum," Book 2, Aphor. xxvi.), says: "When in the investigation of any nature the understanding is so balanced as to be uncertain to which of two or more natures the cause of the nature in question should be assigned, on account of the frequent and ordinary concurrence of many natures, Commanding Instances show the union of one of the natures with the nature in question to be sure and indissoluble—of the other to be varied and separable; and thus the question is decided, and the former nature is admitted as the cause, while the latter is dismissed and rejected. Such instances afford very great light, and are of high authority, the course of interpretation sometimes ending in them and being completed."

sical, showed phosphatic opacity in the urine on boiling; I have no record of albuminuria in phthisis; one had scurvy; and one disease of the joints.

I have thought it worth giving this detail just as it presented—an imperfect but true picture. We may venture to make some approximative hypothetical advances. Phthisis is a "natural deviation" of the normal growth or evolution—a "contained variability" of the system, and having the widest general correlations in the body, and to cosmic existences, external to the body. Just as locomotor ataxy has its subjective phenomena even years prior to the so-called "disease," so phthisis has its long preceding subjective nerve phenomena: these are the "perturbations" whose study is far more likely to open to us the laws or "form" of phthisis than will the study of the later stages. The long latent period prior to yet-discoverable lung-changes indicates the almost-perfection of co-ordination of "energy" to growth: the final "miserable" growth of tubercular cell-forms; or the final loss of "energy," allowing the evolution of bacteria, appear in a natural series of organic cycle, being absolutely correlated or dependent on, or in true necessitous "continuity" with, the latent preceding conditions. I contemplate these long-hovering unstable-equilibrium cases with the deepest interest, in the hope to perceive how they are differentiated from those cases which are more rapid: no "specific entity" or fact marks their differences, but a true gradation of series.

In the face of so great a variety of anatomical and functional deviations, and in an age of the revival of true method—in the disappearance of the "specific" from all the great regions of thought and knowledge—we shall surely never again look on phthisis as a "specific entity" or disease whose greater "form" is in bacteria, or any other single cause, save in some altered "mode" of "energy" dependent on deficient matter, and involving the largest "forms" of biological evolution or development. But not to be too speculative, the fact remains, that some individuals will have the varied series of pre-phthisical neuroses, during many years, without further evolution of disease; whilst in others the lung disease will evolve earlier. I have a long list of these hovering cases, but I fail to potentially differentiate them; nor is my grasp of nerve pathology, physiology, or structure equal to the more essential localisation of the neuroses and symptoms, in their, so-far, actual cerebro-spinal centres. In some cases the absolute evolutionary or creative forces of the general system seem to be expired; the whole body ceases to grow, just as we not unfrequently see, in young adults, that the thoracic segments have not evolved.

We may remark, both in reference to their order of appearance and their type, that the neuroses and symptoms, though varying in individuals, are generic in their general alliances.

Though unable to potentially differentiate the slow cases from the rapid, one fact is often presented, viz., that patients who work out of doors, as farm servants, or young women who go into the fields, weeding or stone-gathering, &c., though often with imperfect food, yet will preserve their habituated state of health fairly well; but suggestive as is this fact, as to treatment, yet it does not fully explain the slow evolution. As to comparatively rapid cases, there is often easily traceable hereditary atavic types in the bone and skin systems.

We see in the symptoms of phthisis perturbations of nerve energy which must be as absolutely within the range of law as are the more simple perturbations of astronomical bodies. From a more immediately practical point of view we see also an absolute "continuity," a delicate gradation of symptoms, from the most gentle morning-weariness up to the final phthisis of the lungs. We see also that a vast variety of generic antecedent depressions, or changes in environment, are the occasions for the evolution of phthisis.

It must be held as an *a priori* truth that the seemingly complex phenomena are of a truly orderly series: what

Kepler, Dalton, Goethe, &c., did in other, as seemingly vast and difficult realms of existences, will be done in the "varieties" and perturbations of human-being: e.g., How is it that one lung is commonly alone, for some time, affected? Is this "reversion" related to the actual order of the original evolution, but in a backward series? We are as absolutely sure that there must be a "continuity" as we are sure of "continuity" in the correlation of the physical forces. Again, how is it that the pre-phthisical sweat at night? To say that night-sweats are common to many weak people is not to explain the fact; to have even stated the correlation of the phenomena to the so far ultimate nerve and blood supply is no answer. But the fact that we can so far alter and prevent these early night-sweats by "tonics," or change of air, shows that we have control over the deepest molecular forces in operation in the organic evolution, and that slowly-acting molecular forces, as residing in, or rather, as parts of, matter—in some of its elements or states—may reach those further and later devolutions of the organic body which we call phthisis.

(To be continued.)

Clinical Records.

NORTH EASTERN HOSPITAL FOR CHILDREN.

Acute Bright's Disease.

Under the care of Dr. ARMAND SEMPLE.

From Notes by Mr. MONTAGUE WILLIAMS, Registrar.

J. F., daughter of a labourer, æt. 5, was admitted into Connaught Ward on March 29, with the following history: Seven days ago, without any premonitory symptoms, face, trunk, with extremities, suddenly and rapidly became swollen, rendering features unrecognisable in a few hours. Micturition at long intervals. Urine scanty and high coloured. No history of cold. Never had scarlet fever. Had measles and whooping-cough two years ago.

Family History.—Seven children at home in good health. Two have died, 1 from pleurisy and 1 from chest disease. Father and mother in perfect health.

State on Admission.—Temperature 102, pulse 186, resp. 25, weight 43½ lbs. Patient is apathetic, anæmic, with dark hair. The face, abdomen, and extremities are much swollen and everywhere oedematous. Eyelids almost closed, features totally unrecognisable. Pupils widely dilated and sluggish. The parts enumerated readily "pit." Abdomen distended, resisting, and rendering palpation of abdominal contents impossible. No appreciable fluid wave. Skin harsh, dry, in parts glossy and tense. Heart and breath sounds normal. Pulse 160, thrilling and compressible. Tongue much coated with creamy fur. Ordered, mixture diureticae 3ss 4t horis. Milk diet. Towards night became drowsy. Pupils dilated. Ordered

Pulv. jalapæ co., gr. xx;

Ac. pot. tart., 3ss.

Statin

Hot vapour baths (110° F.) for twenty minutes. Slight diaphoresis produced. Passed four ounces of apparently healthy urine. Is sleeping.

Examination of urine sp.g. 1013, alkaloid, almost solid with albumen. Heavy deposit of phosphates. Cloudy. Microscopic examination reveals abundant hyaline and granular casts, with a few red blood-cells.

April 2nd.—General oedema considerable. Eyelids closed. Right latia magna swollen considerably. General hyperæsthesia. Southey's capillary tube introduced into right latia and allowed to drip into cakum. One-sixteenth of a grain of pilocarpine subcutaneously injected. Slight diaphoresis. Considerable diarrhoea. Pulse 136, temperature 101.3. Impossible to estimate quantity of urine passed, for it is all voided at stool. Albumen ½ clearer; phosphates.

5th.—Patient is propped up in bed. Oedema less in upper part of body, more marked in lower. Tenderness still complained of. Pulse 100, improving, temperature 100. Pilocarpine one-twelfth gr., slight diaphoresis following. Diarrhoea continues. Is apathetic and fretful. Pupils dilated. Ophthalmoscopic examination reveals fundus healthy. No retinitis.

8th.—During the night passed large quantities of pale

urine, diarrhoea also was excessive. A notable and sudden change for the better this morning. Scarcely any apparent oedema. Legs no longer pit, features small, patient is almost unrecognisable as the same child. Is still very anæmic. Temperature 99, pulse 112, weight 28½lbs., less 16lbs. in 10 days. Urine pale. Not a trace of albumen obtainable. Ordered

Liq. am. acet., 3ss;

Mist. ferri perchlor., 3ss.

T. d. a.

16th.—Complete absence of all oedema this morning. Takes nourishment well (fish diet). Is cheerful. No diarrhoea.

24th.—Is convalescent. Gets up each day. Partakes of a meat diet. Is gaining flesh.

May 4th.—Has gone home to-day, in good health.

Transactions of Societies.

CLINICAL SOCIETY OF LONDON.

FRIDAY, MAY 23RD.

The President, ANDREW CLARK, Bart., M.D., in the Chair.

Mr. W. ANDERSON on

PYELO-LITHOTOMY.

The patient, a joiner, æt. 20, was admitted into St. Thomas's Hospital in July, 1883. The symptoms, of nine months' standing, were characterised by the presence of hæmaturia and pain in the left loin, aggravated by exertion and relieved by rest. The urine deposited crystals of uric acid, but contained no admixture of pus. Some fulness and tenderness in the loin, with increase of the area of percussion-dulness, appeared about a week before the operation. An operation was performed on the 10th September, 1883, under strict antiseptic precautions. The kidney was reached by an oblique incision three and a-half inches in length, parallel to, and three fingers' breadths below, the eleventh rib (the twelfth rib was not to be felt externally). On exposure of the organ, a stone was detected by digital exploration in the pelvis renalis, and was reached by incision of the membranous wall of the duct. An attempt was made to extract the calculus by means of the forceps, but failed in consequence of its firm fixation. It was then dislodged by the finger; no hæmorrhage occurred after the completion of the parietal incision. After the insertion of a drainage-tube, the wound was closed with silk sutures, and dressed antiseptically. The progress was uninterruptedly good, except for the appearance of slight toxic symptoms, due to absorption of carbolic acid, on the second and third day after operation. The urine escaped through the wound in small quantity during the first twelve or eighteen hours, after which the whole of the secretion was passed *per vias naturales*. The discharge remained aseptic throughout. The temperature rose to its highest point, 102° 2', on the second day, and sank to the normal level at the end of ten days. The drainage-tube was removed on the seventh day, and the antiseptics were abandoned after the end of the second week. By the middle of October, about five weeks after the operation, the wound had become reduced to a superficial sore, and the patient was able to get up and walk about the ward without pain. The urine presented only a trace of albumen and a few cell forms. He was discharged cured on the 1st November. The calculus weighed sixty grains when entire, and consisted chiefly of calcium oxalate, with about 10 per cent. of uric acid and traces of magnesium phosphate. It was shaped like a molar tooth with a rough crown and two fang-like processes between which was a circular sharply margined depression. A piece of renal substance had become embedded in the depression, and was so firmly adherent that it was torn away from the organ during the extraction of the stone. The case was referred to as the eighth of the published examples of operation for removal of a stone from the kidney by incision through the healthy parietes. Of the eight cases seven were successful, one ended fatally. The main element of the calculi was uric acid in two instances, calcium oxalate in four, and calcium phosphate in two; and the weight ranged between twenty-six grains and one ounce. The operative procedures differed principally in the treatment of the kidney; in six cases the stone was reached by section of the renal substance; in two by incision

of the pelvis renalis; severe hæmorrhage resulted in two of the former group, but was checked by pressure. The cure was perfect in the cases of recovery, and in no instance was permanent urinary fistula a sequel; the secretion ceasing to flow through the wound after an interval ranging from eighteen hours to eighty-one days. The name of pyelo-lithotomy was proposed to distinguish cases in which the stone was extracted through an aperture in the pelvis renalis from cases of nephro-lithotomy in which the renal parenchyma was incised for the same purpose. It was suggested that the former procedure, when practicable, was preferable to the latter on account of the removal of the danger of wounding the large vessels in the neighbourhood of the ileum, while in the two cases in which the plan had been adopted, the flow of urine through the wound speedily ceased, before the end of eighteen hours in one instance, on the sixteenth day in the other. As incidental points for notice in the case recorded, mention was made, firstly, of the absence of the enlargement or displacement of the kidney that might have been anticipated from the lumbar fulness, dulness, and tenderness observed before the operation; and secondly, of the impossibility of distinguishing the twelfth rib by external examination, the lowest palpable rib being the eleventh, a peculiarity which, if undetected, might bring the pleural sac into danger.

Mr. GODLEE advocated removal of the kidney in cases where extensive disease of the organ was indicated by the passage of calculi in size and number resembling those exhibited to the Society. In nephro-lithotomy the hæmorrhage was by no means so alarming as had been assumed, and it could be very quickly arrested by compression. Complications might be expected in the pelvic operation. He had operated on a kidney the structure of which was very much torn during the proceeding, and no evil results ensued.

Sir ANDREW CLARK thought the paper offered suggestions to the effect that the diseased condition might have been associated with improper feeding, or by a constitutional defect influencing nutrition; and he inquired whether this had occurred to Mr. Anderson?

Mr. H. MORRIS considered that it was still too early to decide definitely whether it was better to select the kidney or its pelvis as the site of incision; a greater number of cases was required for comparison, and it would most likely be found desirable to choose that part of the organ at which the enclosed calculus projected most prominently. Often, however, it was discovered that the pelvis was almost entirely destroyed, the stone presenting at the surface of the kidney. He thought unnecessary complications of terminology would be introduced by applying a new name to every modification of operation in this connection. The question of hæmorrhage need not concern the surgeon, for it could always be readily controlled after the first gush, by compression. Its amount was less if, after incising the kidney by aid of the knife, the fingers were employed to tear down the tissue of the organ until the stone was reached and removed, the finger itself serving to arrest the bleeding by acting as a temporary tampon. The question of fistula must also be held to affect the choice of site, and he was not convinced that a preference could be awarded to the pelvis on this account. Two weeks ago he removed a stone weighing 89½ grains, and the following day the patient passed 60 ounces of urine *per vias naturales*; and although Mr. Morris fully expected that some would escape through the wound, none had since pursued this direction. He considered it quite justifiable to make even a large incision in search of a stone when the symptoms of a case render its existence in the kidney positive, and when the calculus could not be otherwise discovered. He had performed nephrectomy in one instance where exploration failed to expose the stone, and in which, after removal, the organ was found to be in a healthy state; had sufficient exploration been resorted to, the kidney might have been preserved to the patient. He would advise exploration of the bladder in cases of suspected stone, prior to extirpation of a kidney, in both sexes; by a median lithotomy incision in the male. He was led to this conclusion by recent experience of a case, in which a calculus was discovered buried in the bladder wall at the entrance of the ureter. Symptoms of stone had extended over six months.

Mr. ANDERSON said he had made full inquiries into his patient's history, and could find nothing to account for the condition he was in. The fact that all the calculi came from the left side was proved by the site of the pain experienced

during their passage. He did not advocate the pelvic operation, save under certain circumstances, in which it might prove of service.

The Secretary read for Dr. FINLAY notes of

THE SEQUEL OF A CASE OF AORTIC ANEURISM.

The case was first brought forward, and the patient, a female, æt. 32, shown at a meeting of the Society on the 10th February, 1882. A full report appears in the "Transactions," vol. xv., p. 151. She presented well marked signs of a sacculated aneurism of first part of the aorta, with aortic and mitral incompetence, and had been treated for six months in the Middlesex Hospital on Mr. Tufnell's plan of restricted diet in the recumbent position, with increasing doses of iodide of potassium. For two years and a-half subsequently she had attended as an out-patient, having taken almost continuously iodide of potassium in considerable doses. The question proposed for discussion when the patient was shown was the propriety or otherwise of operative treatment by electrolysis, or the distal ligature, the arguments for and against which were stated in the paper then read. As independently of other considerations, she was unwilling to be again laid up in the hospital, it was resolved merely to continue the treatment with iodide of potassium, and she attended regularly at the out-patient department once a fortnight, until her death, which took place on March 26, 1884. On the last occasion on which she was examined (viz., on 18th January, 1884), she stated that she felt better in her general health than she had done when first shown at the Society's meeting in 1882. As to her physical condition, the notes then made were practically the same as those read on the former occasion. On March 22, however, she was seized with shortness of breath, cough, and pain in the chest, and she died on the 26th with symptoms of bronchitis and congestion of the base of the left lung. At the post-mortem examination the aneurism was found to be adherent to the cartilages of the second, third, and fourth ribs on the right side, and to the adjacent part of the sternum. The sac, which was divided into two parts by a calcareous ridge, sprung from the aorta immediately above the aortic valve, and contained some loose, soft, decolourised clot. It was roughened and thickened by patches of atheroma, which had proceeded in many parts to calcification. Part of the sternum and of the cartilages of the third and fourth ribs was eroded. The cusps of the aortic valve were thickened, puckered, coherent, and obviously incompetent. The muscular substance of the heart was pale and soft, and under the microscope showed advanced granular degeneration. The lungs were oedematous, and the base of the left was congested and pliable, breaking down under pressure with the finger. The results of the post-mortem examination bore out the conclusions arrived at when the case was first brought forward. In particular, the condition of the aortic valve established the fact of the aortic regurgitation, regarding which doubts had been expressed when the patient was shown. As to the effect of treatment, there was no deposit of fibrin or consolidation of the sac. Probably all the methods of treatment used acted in the same way by lowering the blood pressure. It was worthy of note that the aneurism was not directly the cause of death, which was due rather to the degeneration of the heart's substance, consequent upon the incompetence of the aortic valve.

Mr. GOLDING-BIRD on

TWO CASES OF HERNIE EN BISSAC IN WOMEN, ONE BEING INTRA-PARIETAL.

The first was a woman, æt. 47, on whom he had operated in 1878 for right femoral hernia, opening the sac and removing omentum. In December, 1880, he again operated for fresh strangulation and then found the peculiar condition described, but of which there is no mention in the notes of the first operation; presumably, therefore, it had developed subsequently. Now, besides the usual and large hernial sac, there was, leaving it at right angles, a process of sac just the size and shape of the finger (thumb) of a glove, and passing down into the right labium. It left the parent sac just below the pubic spine. The main sac was, at the close of the operation, dissected up and removed, being ligatured at its neck, but the labial portion, being firmly attached, was cut off and left *in situ*. There appeared to be every prospect of a radical cure resulting. Though strictly the term *en bissac* was applicable only to inguinal hernia, yet he had employed it here, so exactly did this hernia agree with the requirements for that condition save in regard to its

position in the thigh. The other case was that of a woman, æt. 60, with twenty years' history of left inguinal hernia. After wearing a truss the first ten years it disappeared until two years ago, when, in addition to the inguinal protrusion, there developed a large and subcutaneous tumour, lying above Poupart's ligament and between the crest of the ileum and the external abdominal ring. Twice it had appeared and then in a few days nearly subsided, but failed to do so on a third occasion, the beginning of this year. Kelotomy was performed, and it was then found that whilst the original hernial protrusion existed at the external ring, a large and laterally-connected sac had burst through the front part of the inguinal canal, leaving only a broad external pillar, and lay in the aponeurosis of the external oblique. The bowel was relieved, after division of the internal ring, without opening the sac; this was then opened and much inflamed omentum removed. The patient sank from exhaustion on the third day. Mr. Golding-Bird referred to a case of Mr. Luke's, published thirty years ago, almost identical with his own; but the great peculiarity of this case he considered to be in the double sac; the absence of taxis or any violence ever having been employed to induce its formation; its bursting through the external oblique fibres in front of the canal, and its subcutaneous position, that of intra-parietal hernia being always inter- or sub-muscular.

Dr. F. TAYLOR read notes of a case of

IMPACTION OF A BONE IN THE LARYNX,

contributed by himself and Mr. Golding-Bird. A man, æt. 63, came to Dr. Taylor's out-patients for a cough which he had had more than five months. Though he did not complain of his throat, a slight stridor led to an examination of the larynx, when a foreign body, resembling bone, was seen lying below the cords, and extending from front to back of the larynx. It appeared to be about $\frac{1}{2}$ in. broad, but there was breathing space on either side of it, and on phonation the cords closed easily over it. On being questioned he remembered that four months previously he had taken some sheep's head broth, and half-swallowed with it a piece of bone. This stuck in the back of his throat, and he was unable to move it with his fingers, but his wife with the tablespoon pushed the bone down his throat, and he thought it was safely disposed of. For a week his throat was sore, and for two or three days he spat some blood, but since then he had not had any inconvenience from it. He was admitted into the hospital, and was found to have the physical signs of emphysema, with expectoration of much frothy mucus, and metallic cough, preceded by stridulous inspiration. After a few days he was transferred to a surgical ward, and Mr. Golding-Bird proceeded to remove the bone by laryngotomy. On dividing horizontally the crico-thyroid membrane, and putting in a tracheal dilator, the bone was at once seen, and removed with Tynbee's ear forceps. A second smaller piece, the size of a pea, was seen impacted in the mucous membrane covering the cricoid, and also removed. The patient made a rapid recovery, and when seen again, two years later, the larynx appeared normal; the cords moved freely, but were slightly pinker than usual. The larger piece of bone removed measured $\frac{3}{4}$ in. in length, $\frac{1}{2}$ in. broad, and $\frac{1}{4}$ in. thick. Attention was called to the large size of the foreign body, the curious way in which it became impacted, its long retention without inconvenience to, and, indeed, without the knowledge of, the patient. Its large size, and the apparently firm impaction below the cords led to the adoption of the external operation rather than its removal by the mouth.

Dr. DE H. HALL asked if any attempts had been made to remove the foreign body, by means of forceps, prior to operation?

Dr. COUPLAND instanced two cases of obstruction of larynx by foreign bodies. In one a portion of necrosed bone had become detached from the bone of the skull in a syphilitic patient, and was found, post-mortem, in the glottis. In the other, a man, pleurisy and pneumonia were diagnosed, but after a week or two, the patient expectorated a large fragment of mutton bone which had been swallowed some time before with some broth. The lung cleared, and good recovery ensued.

Mr. GOLDING-BIRD explained that removal by forceps had not been tried, because the bone had been *in situ* three months, was firmly impacted, and presented "broadside on," so that its removal by such means must have been difficult or impossible without great injury to surrounding parts.

Dr. TAYLOR agreed with Mr. Golding-Bird's remarks.

Living specimens were exhibited by Mr. Bernard Roth (a remarkable case of lateral spinal curvature), and by Mr. Howard-Marsh (removal of dislocated astragalus; cases of hernia).

ACADEMY OF MEDICINE IN IRELAND.

MEDICAL SECTION.

A MEETING of the Medical Section was held at the College of Physicians on Friday evening, April 18th, Dr. HENRY KENNEDY in the chair.

ETIOLOGY OF CLIMATIC FEVERS IN INDIA.

Dr. J. W. MOORE read an abstract of Surgeon-Major Gore's paper, which was before the section, *in extenso*, at the previous meeting, when, owing to the lateness of the hour, the discussion was adjourned. Surgeon-Major Gore showed that the common climatic fevers of the Kumaon Hill ranges of North-West Bengal presented themselves under two very distinct forms—namely, as intermittents and remittents. He disputed the doctrine held by some, that remittent fevers were not to be met with in India as distinct from enteric fevers, and quoted briefly a description of the severe epidemic of malarial fever which prevailed in the neighbouring north-west provinces in 1879, which differed in no respect from that met with in many parts of Lower Bengal. Having alluded to the aqua-malarial fevers of the mountain regions of North America as described by Waggoner and Smart, he referred to the observations of Macnamara and Walker on the presence of malarial fevers in the hills in India, and to the great varieties in the degree and severity of the types of malarial fever which often obscured the diagnosis between malarial and enteric fevers. He showed how malarial fevers varied in intensity and duration according to the dose of the poison, exposure to intense heat, individual peculiarities of constitution, different altitudes, the causes of scurvy or acquired anemia from a previous residence in the plains, giving examples from the record of the 30th Regiment. At the same time he pointed out how the malarial fever might ascend, and in how many different ways it might be taken into the system, and how the quinine test might be vitiated by a variety of circumstances, and what therapeutical combinations were necessary to render it effective; alluding to those congestive remittents caused by an excessive dose of the poison, or the nervous system or blood being so altered from the natural standard as not to be amenable to any therapeutical combination which might be administered to avert a fatal termination.

The CHAIRMAN confessed that medical men in this country were not likely to throw light on the etiology of climatic fevers in India, and observed that for a long time it was thought that typhoid fever did not exist in that country.

Dr. J. W. MOORE said the members of the section were unanimously of opinion that they were indebted to Surgeon-Major Gore for his paper.

The REGISTRAR-GENERAL (Dr. Grimshaw) concurred, and said the paper was more for instruction than discussion, the members having absolutely no experience of the forms of fever described.

DISEASES OF THE BLADDER.

Dr. J. P. DOYLE read a paper on a case presenting some symptoms of disease of the bladder. A gentleman, æt. 68, came under his care in May last for irritability of the bladder and pain along the urethra, especially about an inch from the orifice. He consulted a London specialist, who, from the symptoms described, expected to have found a calculus, but afterwards diagnosed enlargement, with hardness, of the right lobe of the prostate, which, he said, by pressure on the nerves, produced the pain, numbness and lameness in right lower extremity from which the patient suffered. He also informed him that he would not be free from the pain during his life. On the 18th of January, inflammatory symptoms with great pain set in. The slightest touch or movement produced increase of pain with contraction of the muscles of the thigh, which, in a few days, became very tense and swollen, and later on some stercoaceous vomiting ensued, along with great tympanitic distension of the abdomen. The patient got great relief from puncturing the abdomen with the needle of a hypodermic syringe in the position of the ascending colon which allowed of the escape of a large quantity of very of-

fensive gas. On post-mortem examination no calculus was found, and the bladder and prostate were normal. The veru montanum appeared enlarged. The cæcum, ascending colon, and vermiform appendix were found inflamed. The former were distended, and contained dark-coloured matter like moist charcoal, and the latter was filled with a hard mass which, on fracture looked like charcoal.

The CHAIRMAN said it was a critical case for diagnosis, and asked was there perforation.

Dr. MORE MADDEN considered that all the symptoms pointed to disease of the bladder, including displacement of the cæcum, which gave rise to an amount of trouble sometimes under estimated.

The CHAIRMAN had not seen any case where the thigh was involved, but he had seen one where the pain was down the right thigh. He did not think the prostate gland had anything to do with it. Possibly true diagnosis could have been made during life.

Dr. DOYLE in reply said there was no perforation. The man had enlargement and hardness of the prostate. Contrary to what the authorities mentioned, the patient never lay on the diseased side, but on the opposite. He was stated to have had a gouty rheumatic tendency.

PROGRESSIVE MUSCULAR ATROPHY AND LABIO-GLOSSO LARYNGEAL PARALYSIS.

Dr. J. MACGEE FINNY read a paper to show the identity of progressive muscular atrophy, and progressive bulbar paralysis. He drew attention to the rarity of labio-glossal laryngeal paralysis. Erb wrote his article in Ziemssen's Cyclopaedia of Medicine from a personal knowledge of but nine cases; Hammond of but six; and he himself had met with but three cases—one while a student, and the other two the subject of the paper. Each of these diseases occurs perfectly independent of the other. Of Erb's nine cases, six were of pure bulbar paralysis. Nevertheless, progressive bulbar paralysis is one of the commonest terminal complications of progressive muscular atrophy, and, on the other hand, any atrophic lesions are found with, or subsequent to, the occurrence of bulbar disease. He did not discuss the relative merits of the myopathic or neuropathic theories of the origin of the two diseases; but he referred to the light thrown on the essential identity by the microscopic demonstrations of Charcot, and more recently Fox, of the lesion engaging the grey nuclei on the floors of the fourth ventricle, and the multipolar cells of the anterior grey cornua of the cord at the same time, by the analogy of these parts as revealed by anatomy and physiology, and by the striking clinical resemblance of the symptoms. The two cases, the subject of this communication, were men of the labouring class both from the country—one æt. 50, the other 39—who came under his care in the spring of 1882, of seven and nine months' duration respectively. In both, disease began without any discoverable cause predisposing or exciting in the tongue by impairment of speech and difficulty of deglutition, and after five or six months' evidences of progressive muscular atrophy were perceived, although it was very probable that its occurrence was considerably earlier. The bulbar symptoms were extremely well-marked in each, though one differed from the other by the amount of glossal atrophy, and the involvement of the lips. Fibrillary movements were noticed in the tongue of both, and in the lips of one. The constant dribbling of saliva, the difficulty of pressing the lips to blow smoke or spit, the difficulty of carrying the particles of food to the back of the mouth were well-marked, while speech was reduced to "aye" and "no" in one patient, and to a few monosyllables in the other. In both the dental and labial letters were impossible, and in one, suffocative attacks from the food entering the larynx were frequently imminent. The changes were well-marked in the neck and upper extremities of one and both arms and legs in the other. Fibrillary movements were most distinctly seen in all the paralysed muscles. Sensation and tendon reflexes were unimpaired, and there was no paralysis of the bladder or rectum. In one, treatment by barium chloride and frequent galvanism and faradism seemed to arrest the progressive muscular atrophy, and even to restore to the deltoids the power they had lost, while the bulbar symptoms remained unaltered, though not increased. The other case was rapidly wasting, and the bulbar symptoms were worse. Both cases left hospital, and their future progress was unknown.

Dr. C. J. NIXON observed that in bulbar paralysis there

was always to be found a constant lesion in the motor roots of the nerves and the motor ganglia, and the medulla. In all the post-mortem examinations there had been found constant trophic change in the motor roots of the nerves, whereas in nineteen recorded cases of progressive muscular atrophy no change whatever was found in the motor roots, and another peculiarity was that the first sign was the atrophic condition of the muscles, while there were some cases recorded where, with distinct bulbar paralysis, there was no atrophy of the muscles at all. The absence of atrophy of the muscles could be explained by assuming the disease confined to the motor cells in the anterior grey horns, while the trophic cells in the neighbourhood had escaped the disease. He asked how Dr. Finny explained the number of cases met with by reliable observers where there had been no disease found in the cord at all in cases of progressive bulbar atrophy. Another point was as to what distinction they were able to draw between cases of progressive muscular atrophy and the acute or sub-acute forms of polio-myelitis. In polio-myelitis they first had paralysis and subsequently atrophy, whereas in progressive muscular atrophy they first had atrophy, and then in proportion to atrophy of the muscles they had loss of motor power. There was a great amount of evidence to show that those diseases were to a large extent hereditary.

The CHAIRMAN pointed out that there were cases recorded of local origin in which there was no disease found in the spinal marrow or the brain.

Dr. FINNY, in reply, acknowledged that Dr. Nixon had touched more points than he had dealt with in his communication, but he thought it was hardly time yet to come to any positive conclusion in comparing the two diseases, the number of observations on progressive muscular atrophy being much larger than that on bulbar paralysis. The microscopic examinations in the latter were very few, whereas the other disease had been the subject of general observation for many years. It was not in his power to explain the observations of Charcot, as to the absence of lesions in the anterior grooves of the cord in progressive muscular atrophy. If his theory was correct, one of the essentials must be an ascending neuritis, and this, passing through the muscles, should show itself in the anterior roots before it reached the grey matter in the cord. There might be no lesion of the anterior cord at all. In infantile palsy rapid inflammation, or other lesion, took place in the multipolar cells, whereas in muscular atrophy the same process was going on much slower, and partially progressive muscular atrophy existed; but there were many cases where, before the atrophy was fully confirmed, they had paralysis, and that in bulbar paralysis. In Charcot's case the lung was perfectly normal, but after death the examination showed it was in a very advanced stage of fatty degeneration. The amount of atrophy was somewhat due to the nutritive nerve cells which must preside over those parts. As to the etiology of the disease, so far as his knowledge went, there was little known about it. He did not agree with Dr. Nixon that hereditaryness was shown to be a factor in those cases. It was not so in his cases, which he had brought forward, not to prove any special theory as to the origin of the disease, but to illustrate the close affinity existing between the two diseases.

ATROPHY OF OPTIC NERVES AND PARALYSIS OF FIRST AND FIFTH FROM PROBABLE TUMOUR IN THE BRAIN.

Mr. STORY read a paper on the atrophy of the nerves and paralysis of first and fifth from probable tumour in the brain, the discussion of which was, owing to the lateness of the hour, postponed to next meeting, and
The Section adjourned.

IN the principal foreign cities the rates of mortality per 1,000 of the various populations were, according to the latest official returns, as follow:—Bombay 28, Madras 84, Paris 28, Geneva 29, Brussels 23, Amsterdam 24, Rotterdam 34, The Hague 24, Copenhagen 22, Stockholm 27, Christiania 20, St. Petersburg 38, Berlin 24, Hamburg 29, Dresden 29, Breslau 31, Munich 38, Vienna 35, Prague 40, Buda-Pesth 38, Turin 28, Venice 13, Lisbon 29, New York 24, Brooklyn 20, Philadelphia 20, and Baltimore 21.

Special Articles.

THE 13TH CONGRESS OF THE GERMAN SOCIETY FOR SURGERY.

[SECOND NOTICE.]

HERR LEISERINK showed his Turf Mould Felt. Since the last Congress it had been extensively used. It was clean, cheap, and had great absorbent properties, and was of great service in cases in which the discharge was profuse, as in incontinence of urine for example. By its use the bed was kept perfectly clean.

Herr Busch demonstrated a preparation of a diverticulum of intestine forming a crural hernia. The patient, a man, æt. 53, was brought into hospital in such a desperate condition that no attempt could be made for surgical relief. On examination after death, the abdomen was found filled with fecal matter. On the right side there was a hernial sac, but it was empty. A small diverticulum was found in the small intestine about 75 c.m. above the cæcum. It was not gangrenous, but at its base was a small perforation.

Herr Partsch (Breslau) showed four patients on whom Ogston's operation had been performed, and gave some particulars as to the final results of the operation. He thought the unfavourable judgment that had been accorded the operation was not justifiable. In the years 1878-84 23 cases of genu valgum had been operated on in the Breslau Clinic, by Ogston's method, 11 bilateral, 12 unilateral. In every case the disease had not been produced by rickets, but by the nature of the patients' employment (bakers, sailors, countrymen, &c.). All the cases were operated on without the spray. In none of the cases did the temperature rise above 39° C. (101° F.), the morning temperature was always normal. In two cases he observed reflex paralysis of the detrusor urinae muscle which passed away in two days. The dressing was an occlusion one of sublimate with an elastic bandage. Only once was the dressing removed on the ninth day on account of erythema with eczema, which starting from the wound spread over the whole body. Checked growth could not be made out in the patients shown. The objection that arthritis deformans might come on later is one difficult to meet.

Herr Volkmann thought that Ogston's operation was to most surgeons of merely historical interest. The operation was altogether too dangerous, and even one hundred successful cases would not modify this fact; for the first fatal case would place it in its proper position. In the present extension of surgery, in which a constantly increasing number of medical men practice it, it became their aim to discover operations in which a single little error, likely to happen to the novice, and which might indeed happen to any one became pregnant with fate to the patient. These kinds of operations he called surgical rope-dancing, and was sorry that if anyone did fall from the rope it was not the doctor but the patient. No one could guarantee that a knee-joint would not suppurate after the operation. A great number of patients had died after it, but all the cases were not published. The same result could be achieved by operation that did not touch the joint. The objection of later arthritis deformans was a very important one.

Herr Lunge (New York) was in a position to illustrate the disturbances of growth that might follow the operation.

Herr Mikulicz thought simpler and safer operations rendered the discussion objectless. If the writer of the paper could not prove that stiffness and limitation of function never came on, the results would leave something still to wish for. He knew two cases of Ogston's operation in which a stiff joint remained. Ogston, himself, had given up the operation.

Herr E. Hahn (Berlin) reported five cases of extirpation of the larynx for carcinoma. Two of the patients died soon after operation of pneumonia, and the remaining three were exhibited. One, was a man, æt. 71, who had been operated on 3½ years previously, and had continued quite well, the others were of more recent date. Statistics showed that of 52 total extirpations on record 34 died in consequence of the operation, or shortly afterwards, whilst only one died of 11, on whom half had been removed. The disease recurred in 14 cases after total extirpation, and in 3 of those in which half had been removed. When one bore in mind that the function after semi-removal was improved, that the

patient could speak quite well, and that the canula could be dispensed with, it would be seen that this was the operation to be recommended.

Herr Schede showed a patient on whom semi-extirpation had been performed in October, 1882, and who had completely recovered functional power. The canula was worn until last year, and then removed. The wound healed rapidly and some bronchial asthma that came on afterwards was now completely removed. The laryngoscopic appearances were interesting, as they showed in a typical manner an apparent new formation of the vocal cord on the extirpated side. The results following the operation from various causes were now much better than after the early operations. The cases shown decided the question of the propriety of the operation.

Herr Küster also showed a patient, a medical man, on whom he had operated four times, and who, after a lapse of three years from the time of coming under treatment, was able to follow his occupation.

Herr Partsch demonstrated a method of preparing bones by a simple process, consisting of macerating the bones in a three to five per cent. solution of caustic potash previously heated to 35° or 37° C. (96 to 98½ F.).

Herr Schede (Hamburg) read a paper on resection for carcinoma of the small intestine, with demonstration of preparations. The tumour was on the left side just above Poupart's ligament. It could not be reached *per rectum*. An incision was made May, 1883, in the line of the ligament and he was quickly convinced that the tumour was malignant. After further opening the peritoneum, he was disagreeably surprised to find that it could not be withdrawn, but was continued into a loop of intestine. Nothing remained, but to extirpate this together with a piece of mesentery. Both ends of the intestine were ligatured with silk and severed. The divided ends were united by a circular continuous suture, dropped, the abdominal walls were united and the patient was discharged well in August. In February of the present year, the patient was examined and no trace of relapse was discoverable. At the end of March, he was again admitted into hospital with stercoraceous vomiting of four days continuance. Herr Schede naturally expected a return of the disease; the patient, was however, so much exhausted that he contented himself with making an artificial anus. As experience had taught him that in cases of ileus, one had to abstain from more vigorous measures until a normal condition of affairs had been brought about, he made an incision above the old one and found no return of disease, but a strangulation in the vicinity of the old operation, apparently caused by a firm band. He now prolonged the opening and freed a pseudo-ligament that had constricted the intestine. After removal of the constriction the intestine filled, and the same day the patient had a motion. The patient did well for a day or two when the temperature rose to 40° C. (104° F.) and then died of pneumonia.

Herr Madelung had for some time used the uninterrupted suture and had made an artificial anus four times with success.

Herr Mikulicz (Cracow) read a paper on the "Arrest of Hæmorrhage by Tampons and Compression." The speaker remarked that there were circumstances under which it was desirable to conclude the operation as quickly as possible, or in which ligation was difficult. For use under such circumstances he had prepared a compress for the cavity of the wound to check the hæmorrhage. This consisted of a pair of forceps, each end of which was armed with a pad. One pad was crescent-shape made movable by means of a ball-joint and intended to be placed outside. In regard to compression he narrated a case in which the arrest of hæmorrhage could only be effected by compression. The patient was a man, æt. 31, who had a very vascular tumour in the neck, which dipped down into the supra-clavicular fossa and here compressed the blood-vessels. The operation of removal was exceedingly difficult, as the attachments had to be separated step by step. In attempting to draw out the tumour, the jugular vein suddenly gave way just at its junction with the subclavian. Ligation was not successful, and a large quantity of air was drawn in, so that complete asphyxia came on. The cavity was filled with iodoform gauze in order to enable the patient to be brought round. The operation was then quickly completed, the whole cavity filled with iodoform gauze, and pressure made by means of an elastic roller. Eighteen hours afterwards the dressing

was removed and the wound brought together by suture. Healing took place by first intention.

Mr. Davidson (Aberdeen, Scotland) showed and described an instrument called a lithophon.

Herr von Bergmann (Berlin) reported a case of traumatic aneurism of the subclavian artery cured by two hours compression.

Herr Volkmann begged the members present to relate their experiences on the subject of wounds of the great blood-vessels as he had seen only a single case. He considered that ligation of the subclavian was a great and difficult undertaking as osteotomy of the clavicle had first to be performed in order to clear the way to the region operated on.

Herr von Langenbech reported three cases of traumatic aneurism of the subclavian. In two of the cases enormous sanguineous infiltration had taken place. The aneurism was opened out in these cases, the vessel compressed with the hands and the two ends ligatured separately. He counselled early operation.

Herr von Bergmann agreed in this opinion, but laid stress on the possibility of an expectant treatment as in his own case.

Herr Madelung (Rostock) followed with a paper on the shelling out of varices of the lower extremities, in which he recommended this form of treatment.

Herr von Langenbech had operated by this method in a series of cases with good result, but in one case, after the lapse of three years, a number of new venous stems made their appearance. He should fear that in bad cases a return of the affection would take place.

Herr Schede now operated in the same manner described by Herr Madelung.

Herr Czerny (Heidelberg) showed two preparations from resections of the stomach. He warned his colleagues against operating if the disease, and especially, the tumour, had encroached upon the meso-colon, as gangrene of the colon always followed, as Lauenstein had shown, and his own observations unfortunately confirmed one case. The fear of a return of the disease should not deter from operation, as the subjective condition of the patient, cured at least temporarily was an eminently favourable one. The second preparation was from a case of perforating ulcer of the stomach which was operated on successfully. The operation is thus described by Maurer, of Darmstadt, in the *Archiv. f. Klin. Chir.*, Jan. 30, 1884. The opening is made in the longitudinal axis of the stomach, and if possible, the surface of the ulcer is pulled off the thickened wall of the stomach. The edges surrounding the portion removed are then brought together from within, and the wound is closed by deep and superficial external sutures. If the walls of the stomach are too thin to admit of peeling, an elliptical piece is excised, through the whole thickness of the stomach-wall and the edges are then brought together by suture.

Herr Rydygier (Culm) related a case of gastro-enterotomy for stenosis of the duodenum following an ulcer. The patient was a man, æt. 20, who since the age of 16 had suffered from symptoms of ulcer of the stomach, followed by those of stenosis, so that in the end vomiting constantly succeeded the ingestion of food. As it was ascertained that dilatation of the stomach was present, the stomach-pump was employed, but as the symptoms were not relieved thereby resection of the pylorus was decided upon. At the operation stenosis of the first curve of the duodenum was discovered. The speaker closed the wound therefore without further operation, but as the patient was becoming steadily worse, he performed gastro-enterotomy, after which all the symptoms ceased.

Herr von Winiwarter (Liège) reported a case of defect of the bony skull from injury. He considered that the defect arose from absorption of the bone after injury in childhood. The face on the side of the injury was markedly smaller than the corresponding side.

Herr von Langenbech closed the proceedings with the following words:—"As in so many congresses we have this time also made the agreeable observation, that surgery is becoming more and more the common possession of German medical men. Exact observation and the bold surgical hand are no longer only associated with clinics as was the case in former years, but we find in the provinces, in the country district where people work under such great difficulties, the most beautiful results of investigation and operation. With the wish that it may ever go on so, that surgery may ever extend, I close this year's Congress."

Department of Lunacy.

THE DERBY COUNTY ASYLUM.

[SECOND NOTICE].

THE annual report of the Derby County Asylum for the year 1883, is as usual a very clear and able production, and those who differ most from Dr. Murray on the subjects which he passes under review, will freely admit his candour, courage, and simpleness of purpose. He discusses the means of disposing of chronic lunatics, the necessity of provision for idiotic and imbecile children, the propriety of supplying beer as a grant of ordinary diet in lunatic asylums, precautionary measures against fire, and other subjects of interest to all medical men engaged in his own line of practice; and on each subject that he touches, he has some practical observation to offer. His earnest advocacy of the withdrawal of beer from lunatic asylum dietaries, would have more force than it has, if he at the same time insisted on the substitution for the beer of food of an equivalent value, so that it might never be said that a profit had been made on the transaction. Dr. Lindsay relates a curious case illustrating the persistency of suicidal impulses, and their tendency to recur even long after they appear to have been completely banished. A female patient, who had had an attack of melancholia, was discharged recovered at the end of six months residence in the asylum, and was then to all appearances in good mental health. A fortnight after her discharge, while living at home with her husband, having partaken of a hearty dinner, and being, as far as could be judged, in good spirits, she took some red-hot coke and two or three boxes of matches into the cellar, and there making a fire stood over it until her clothes were ignited. Although speedily rescued by her neighbours, she sustained burns from which she died in the course of two days. The only account which she could give of her own conduct, was that she had had "a bad spell."

THE ROYAL LUNATIC ASYLUM OF MONTROSE.

THE Royal Lunatic Asylum of Montrose stands out conspicuously amongst the chartered asylums of Scotland, as an ably conducted institution in which nothing that can minister to the recovery or comfort of those who are afflicted by mental disease, is overlooked. The Scotch Commissioners in Lunacy, who being largely endowed with the national virtue of "canniness," are not wont to be profuse in their praises, warm up to something like enthusiasm when they find themselves at Montrose. "This asylum," says Dr. Mitchell, "has been made complete. The new kitchen, dining hall, and recreation room are all that could be desired. It is not known that anything better could anywhere be seen." "The new accommodation," says Dr. Sibbald, "is of a very high order of excellence. The two new dining halls are exceedingly cheerful and satisfactory in character, and the amusement room is not only suitable for its purpose, but it is a very admirable piece of architecture." The only drawback to the asylum seems to be its geographical situation on the sea coast, for Dr. Howden refers to pulmonary rheumatic affections which have visited the asylum as the result of prevailing cold winds. In certain cases, however, the bracing climate of an elevation facing the German Ocean, may be an advantage rather than a drawback. Dr. Howden alludes to a remarkable case of land scurvy in a mill-worker,

due to insufficient or improper nourishment, which came under observation last year, and goes on to say that he has for many years noticed in female mill-workers brought to the asylum, a type of melancholic insanity associated with feeble health, resulting apparently from insufficient nourishment. Their meals had consisted chiefly of tea and wheaten bread with an occasional bit of ham. Such a diet may, Dr. Howden remarks, be convenient, but it is quite inadequate to support life in health, and is a poor substitute for the substantial porridge and milk, brose and kail of former generations.

THE GLASGOW DISTRICT LUNACY BOARD AND ASYLUM ACCOMMODATION.

THE Glasgow district as determined for lunacy purposes is the largest district in Scotland in respect of population, and its position at the present time for dealing with its insane is very far from satisfactory. The district is chargeable for over 1,200 lunatics, and has only accommodation under the Board's direct control for 180, the remainder being meanwhile disposed of in parochial asylums, in Glasgow Royal Asylum, and in several of the district asylums in Scotland. This condition of matters is a serious handicap to economical and successful lunacy administration, and the District Board has of late years been struggling to put matters on a surer basis. The result of these endeavours has been the purchase of an estate of over 600 acres about fourteen miles from Glasgow on which it is proposed to build an asylum for nearly 1,000 patients. The cost of the estate was over £26,000, and the asylum is expected to cost at the rate of £100 a bed. When we consider that it will consist of chronic and acute asylums respectively, and that the latter is to be fitted up in true hospital style for from 250 to 300 patients, and further that such asylums as Lenzie and Bothwell cost from £250 to £300 a bed, it will be surprising if this new asylum erected in a district responsible for such precedents as Lenzie and Bothwell will not cost at least £150 a bed. It will be gratifying if at the latter price the board succeeds in erecting a really first-class asylum.

THE highest annual death-rates last week in the large towns from diseases of the zymotic class were—From measles, 6·4 in Oldham, 4·1 in Plymouth, 4·0 in Wolverhampton, and 2·0 in Portsmouth; from whooping-cough, 1·2 in Liverpool and in London; from scarlet fever, 1·7 in Newcastle-upon-Tyne, and 1·1 in Cardiff; and from "fever," 1·2 in Norwich, and 0·9 in Blackburn. The 36 deaths from diphtheria included 19 in London, 4 in Nottingham, 4 in Glasgow, and 2 each in Edinburgh and Dublin. Small-pox caused 17 deaths in London (exclusive of 5 registered in the Hospital Ship *Atlas*, moored outside Registration London), 3 in Sheffield, 2 in Liverpool, 1 each in Glasgow, Derby, and Sunderland.

THE publisher of "Ringer's Therapeutics" asks us to mention that the last edition of this work is not absolutely out of print as stated in our last, he having a sufficient number of copies on hand to supply present needs. There will be no new edition for some little time yet, albeit the present one has been recalled from the trade.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, JUNE 4, 1884.

THE DURHAM MEDICAL DEGREE.

WITHIN the past few years the medical degree of Durham University has been steadily acquiring increasing popularity among medical students who aspire to the possession of something more distinctive of professional attainments than a mere license to practise, and who are unable to incur the expense in time and money necessary to graduation at Oxford or Cambridge. For such students there is no pathway to a *bonâ fide* university degree save that afforded by Durham, since the London University is this only in name, while the uncompromising restrictions it imposes on all who present themselves for its examinations, serve to deter many from taking the degree who might otherwise be content to satisfy themselves with such a formal title to university rank. It is therefore regarded as satisfactory by the best friends of medical education, that the Durham degree has been so far placed within reach of all who are willing to sacrifice one year and its attendant expenses in residence within the jurisdiction of the University, for the sake of becoming eligible as candidates for an English degree in medicine; and any proceeding calculated to detract from the value of the distinction is naturally looked upon with the utmost jealousy and distrust. Among these, and by existing graduates who are so by compliance with all the regulations as to residence and examination, as well as by such as aspire to the title, it has long been felt that the University is acting most unwisely in granting its

full M.D. degree to practitioners of fifteen years standing, without residence, and after an examination very much modified in the interest of such candidates. There can be no question, indeed, that the action of the senate in this respect was calculated to imperil the rising success of an important institution; nor did the fact that fifty guineas was exacted from every recipient of the degree detract in any way from the unsatisfactory nature of the regulation. Durham as a centre of medical education is a phenomenon of comparatively new growth, and it behoves it to guard the privileges of its graduates with the greatest circumspection, both on account of its own prestige, and for the sake of those whose confidence in its integrity has led them to ally themselves with its fortunes.

Now, however, as will be seen from a letter in our present issue, an attempt is to be made in the direction of smoothing away the few obstacles that still surround the acquisition of the non-residential degree; a petition to the senate is in course of preparation, praying for the reduction of the practitioners experience from fifteen years to ten, and for a remodification of the modified rules under which the *pseudo* degree is at present obtainable. In opposition to this proposal a counter petition will be presented by *bonâ fide* graduates and students, in which not only is it urged that the restrictions now in force shall not be diminished in favour of practitioners, but that the conditions under which such would-be doctors are permitted to acquire the title shall be altogether abolished. It is impossible not to sympathise with the aims of those who are thus striving to induce the senate to restore to the degree in medicine a full measure of the importance it ought to possess as a proof of higher education. It may not be contended that the traditions of university life and training are maintained by graduates who have never been submitted to any part of the special influence which an academic life exerts; and although the effects of such influence may be less apparent among the medical students of Durham University than in the case of its sister institutions at Oxford and Cambridge, still it is sufficiently large a factor to deserve a prominent place in the list of arguments advanced against the contemplated changes. It is not clear to us either, that the university will be acting faithfully towards its *bonâ fide* graduates by widening the portals through which it has hitherto permitted practitioners to pass to graduation. Everything which at all contributes to diminish the value of the M.B. and M.D., and for which the senate is, or may be responsible, can only be regarded as a distinct and wilful neglect of the interests of those who observe the conditions imposed on regular students of medicine proceeding to the goal of a degree. Such students incur the necessary sacrifices from a belief in the genuine character of the distinction they covet, in proportion to the esteem in which it is held by profession and public. If, therefore, the consideration paid to it is reduced by a removal of the restrictions surrounding it, they who have acquired it by genuine labour will be justly entitled to complain of conduct resulting so detrimentally to their interests.

It is quite pertinent to inquire whether any necessity has arisen to make the suggested simplification desirable ; and the answer is clear that nothing of the kind *has* occurred. The contrary is rather the case, for not only does the London University continue to dangle its degrees before all comers, devoid of all restrictions as to residence ; but also the Irish University is similarly willing to welcome candidates for an M.D. The fact that, in spite of these counter attractions, practitioners still find it advisable to pay fifty guineas for the privilege of a modified examination at Durham, ought to be a significant hint to the senate, and cause it to look for a reason why so determined a preference is exhibited in favour of its qualification. It is not surprising that circumstances of this description have caused unpleasant things to be said of a degree that is brought within the reach of practitioners after fifteen years of rust have gathered upon the knowledge gained during their student experiences. And the somewhat chequered career of St. Andrews, where also a fifty guinea doctorate is conferred without residence, and after modified examination, should have been a warning to the Durham authorities to avoid the doubtful path they have chosen to tread in this connection.

In common with every well wisher to progress in medical matters, we have watched the steady advance of Durham as a School and University of Medicine with great interest ; and it would be a source of much concern to us should there appear any indication that the senate is disposed to retrograde so seriously as it must to accept the proposal to simplify its non-residential degree.

THE EVILS OF AMATEUR DOCTORING.

It almost seems as though the people will never be cured of their material faith in the efficacy of amateur doctoring. No amount or degree of warning appears to have any effect in this connection, and notwithstanding the numerous instances of death through misadventure occasioned by ignorant prescription of remedies, the practice still continues to find favour among increasing numbers of the public. Few cases have brought out the mischief done by amateur prescribing more prominently than one concerning which Dr. Danford Thomas concluded an inquiry on Friday last. In this an old man fell a victim to his daughter's zeal for doctoring every sufferer, from whatever ailment, on a common plan, that, viz., of administering calomel. Being on a visit to her father, this woman persuaded him and his wife to swallow, each, a powder consisting, in her belief, of calomel, the object being to relieve bronchitis. The result was the speedy death of the old man with every symptom of strychnia poisoning ; and of course an inquest was held on the body. One of the witnesses before the coroner was a former employer of the daughter of the deceased, who deposed that he had been accustomed to prescribe calomel for her on account of biliousness and liver disease. By an unfortunate accident, however, a packet containing strychnine, purchased for the destruction of a dog, became mixed with the calomel powders, two of which were recently given by witness to the deceased's daughter, and by the latter administered to

deceased and his wife. One of these contained the strychnine, and its effects were not unnaturally evidenced in the death of the unhappy old man who took it.

With the whole circumstances thus unfolded to them the jury could find no other verdict than that of death by misadventure, which was returned. A mere censure on the witness whose experiences with strychnine thus led to such disastrous results was little more than he could expect to receive ; but it may very well be considered whether the possibility of mistakes like this are not greatly increased by the prevalent custom of prescribing for so-called small ailments by those who possess no knowledge thereon to act aright.

Every one will find it easy to sympathise with that feeling which hesitates to promote any kind of interference with the liberty of the subject by making any suggestion for restricting free choice of remedies by such as need them. Notwithstanding this, however, in view of the really serious occurrences which are by no means infrequent, as the results of amateur doctoring, it seems necessary to make some attempt to influence opinion in the direction of prevention ; and this can only be done by impressing the dangers which attend administration of unauthorised remedies, and the almost certain risk run by every patient who submits himself to the treatment of irresponsible pretenders to medical skill. In the instance narrated above there is a very good illustration afforded of the way in which the tendency to amateur doctoring becomes spread among those who might not improbably fail of themselves to turn attention thereto. The prescribing proclivities of the surveyor who sought to cure his housekeeper's "biliousness" by doses of calomel spread from him to the housekeeper herself, who, as opportunity offered, transferred the knowledge by imitation for the supposed benefit of her own father. The melancholy accident which followed may of course be attributed to pure misadventure, but nevertheless it remains that, had the mischievous practice of amateur doctoring not been indulged in by the first-named witness, it would probably never have affected the daughter of the deceased. Legislation probably cannot reach this question, and private influence must therefore do its best to check the practice.

DOES HYDROPHOBIA REALLY EXIST?

NOTWITHSTANDING Pasteur, and the views universally held by European physicians, the question of the existence of rabies has recently been exercising the minds of the profession in America, Professor Dulles being the champion on the side of those who boldly assert "that hydrophobia is not a specific inculcable disease derived from the bite of a similarly affected animal." This proposition is not novel ; it has been stated and defended before. Professor Dulles is aware of this, and confesses that this view has hitherto failed to secure the assent of the greatest men who, in every generation, have adorned the profession of medicine. He joins the small minority who oppose the time-honoured views of the profession through a sense of duty and for truth's sake. As the *Medical Press and Circular* has been particularly noted for its reports on hydrophobia, and as Professor Dulles criticises in his latest paper in the *Philadelphia*

Medical Times the conclusions of our reports, we feel to some degree interested in the controversy and shall therefore briefly refer to a few of the points raised by the gentleman referred to.

Another writer on hydrophobia in the same journal expresses the hope that Professor Dulles is serious, and that he has not put forward his doctrine on the non-contagiousness of rabies, as a literary mystification, like that published by the learned Archbishop of Dublin, Dr. Whateley, who in his "Historic Doubts Relative to Napoleon Buonaparte," argued that the existence of Napoleon Buonaparte was, to say the least, quite doubtful. Professor Dulles, we believe, is dominated by a sincere desire to assist in the elucidation of the many great questions which arise in connection with hydrophobia; but, like many other sincere men, we consider he is not proceeding on the right track. His attitude of severe criticism is highly commendable; but his criticism, unfortunately, is only destructive and not creative. For nearly two years, he tells us, he has been engaged in a laborious study of the evidence upon which the general belief in regard to hydrophobia rests, and has been gradually led to the conviction that all this evidence is unreliable. In illustration of the contradictions of authors, he quotes a number of authorities ancient and modern, and thus continues: "These citations illustrate the most remarkable feature of the literature of hydrophobia. It would seem as if when once the mind has accepted a theory, which contradicts all experience in other and fairly-well understood diseases, it loses the ability to distinguish good evidence from bad. A striking illustration of this is furnished by Dr. Dolan in his otherwise capital book on 'Hydrophobia and Rabies,' reprinted from the *Medical Press and Circular*. In his second chapter this writer calls attention in detail to the rules laid down by Dr. Abercrombie in his 'Intellectual Powers and the Investigations of Truth.' These warn against the following fallacies:—1. Receiving as facts statements which are not facts but opinions. 2. Receiving as facts statements which only assume the relation of facts. 3. Receiving as facts general statements or the generalisation of facts. Dr. Dolan then says, 'Some writers have, for instance, maintained with much confidence that a particular state of rigidity of some of the limbs is distinctly characteristic of ramollissement of the brain; but further observation has shown that the disease may exist without this symptom, and that this condition of the limbs may appear in connection with other diseases. This observation of facts was in so far correct that this state of limbs does very often accompany ramollissement of the brain; the error consisted in giving it as a general fact, or a fact applicable to all cases of ramollissement which is without foundation. Yet such statements when brought forward with confidence are often received as facts and rested on as established principles; and then the facts by which their fallacy might be detected are apt to be overlooked or forgotten.' To this reference to the commonest sources of fallacy Dr. Dolan adds: 'We are arming our readers against ourselves.' And yet he goes on, apparently with his eyes wide open, to repro-

duce the fault he has just pointed out in speaking of ramollissement, accepting statements which ought not to be entertained for a moment in the discussion of so grave and delicate a subject, and admitting as genuine cases which are transparently spurious." Dr. Dulles then gives in detail the report of a case by Romberg. This case was declared not to be hydrophobia. He said "that he had selected an illustration of the point which he wished to make, which should include two names well known and justly distinguished, because their very excellences add force to the proof they furnish, that the prepossession of a theory which at the onset demands a certain surrender of the judgment will impair the freedom of the judgment at every subsequent step. Such, it seemed to him, is the condition in which every believer in the specific nature of hydrophobia stands." This is criticism which might be legitimately answered by a *tu quoque*.

The general objections of Professor Dulles might be applied to various other diseases, as diphtheria, phthisis, typhoid, whooping-cough, about which there are differences of opinion on their nature and treatment; and just as there are various theories held regarding these diseases so we must expect to have various theories on hydrophobia. This arises from the fact that Medicine is not as yet a fixed science and the problems of disease are difficult. Two great facts stand out prominently. Whatever name we may give the disease it is incontestible that, after the bite of a rabid animal, certain symptoms arise which almost invariably end in death, and just as after the bite of a snake, and just as after poisoning by morphia, strychnia, we connect the symptoms with these poisons, so we associate the death from the dog-bite with the bite. *The bite of a healthy dog never causes the symptoms of the disease known as hydrophobia.*

Call it by what name we will, or explain it how we will, these two facts are scientifically beyond dispute. With such a frame of mind as Dr. Dulles evidently possesses we are afraid that no further evidence we could produce would convince him that he holds not only erroneous, but dangerous views. We must fall back upon the old test proposed by Mr. Whitney, apothecary, Bath, in 1807, in his reply to a Mr. Lee. This Mr. Lee shared views somewhat similar to those held by Dr. Dulles. Mr. Whitney proposed, to test the matter experimentally, that Mr. Lee should inoculate himself with the saliva of a rabid dog, and, as vaccination sometimes fails the first time, that he should do it three or four times. History reports that Mr. Lee declined the experiment.

DR. BALTHAZAR FOSTER, of Birmingham, is, we understand, to be invited to stand in the Liberal interest at the next general election for Newcastle-under-Lyme.

A DEPARTMENT of Dental Surgery is to be added to the existing medical and scientific branches of study in Owens College, Manchester, and the Council will appoint during the present month lecturers in dental surgery, dental mechanics, and dental metallurgy. Applicants can obtain the necessary information of the Registrar.

Notes on Current Topics.

The Council of the College of Surgeons and the Fellows and Members.

WE are glad to find that the agitation against the present system of ruling the Royal College of Surgeons of England is, in accordance with our suggestions, to be persisted in, and that steps are being taken with a view to this result. The principal mover of the resolutions recently ignored by the Council, Mr. Paul Swain, has addressed reply post cards to all the Fellows of the College, requesting their adhesion to the principles for which he is contending. It should be borne in mind in this connection that the original Association of Fellows committed voluntary suicide at the general meeting held on March 24th, when their secretary announced that, having been conceded all the Association was formed to obtain, it ceased to have an existence. Mr. Swain's new Association will propose to obtain much more than the Council has yet consented to yield, and its programme will be based on the meeting's rejected propositions. It is to be assumed that Fellows of the College will unite to give Mr. Swain the pledges for which he asks, and by determined co-operation on their part, it is certain that they will ultimately succeed in securing what is demanded.

At a meeting of the Association of Members of the College, held on Wednesday last, a protest was passed against the action of the Council in respect to the resolutions forwarded from the general meeting in March last. Other resolutions carried were to the effect that no revision of the charter of the College will be satisfactory unless it has received the general assent of the Members and Fellows, and that another meeting of the Members and Fellows should be called to consider such alterations in the charter as may be proposed by the Council. It was determined to immediately prepare a petition for presentation to the Privy Council, praying that a new charter may not be granted to the Royal College of Surgeons until due effect be given to the suggestions made at the late general meeting of Members and Fellows, and further praying that the privileges originally and justly belonging to the Members may be restored to them.

Royal Medical Benevolent College.

THE annual general meeting of the Royal Medical Benevolent College was held at the offices of the College, Soho Square, on Thursday last, the treasurer, Mr. Hird, occupying the chair, and the scrutineers reporting the result of the polling for pensioners and foundation scholars. The two vacancies for pensionerships were filled by the two candidates recommended by the "Committee of Examination," while three only of the seven vacancies for foundation scholarships were so filled up, and the result, so far, may appear to those Governors who advocated the change in the mode of election somewhat disappointing. We can hardly look upon it in that light, as, with fewer vacancies and a larger number of candidates, it will happen that from a greater amount of active canvassing carried on by the friends of some of the candidates, this is sure to occur. A larger number of the

unsuccessful candidates will at the same time creep up to the top of the list, and these will, it may be presumed, have a better chance of election, and quite irrespective of their relative "claims and merits," or the urgency of the case, and which, it must be remembered, determines and limits the action of the Committee of Examination. It is this, too, that influences those Governors of the College who feel bound to abide by the recommendation which comes to them with their voting papers. Under any circumstances, and as canvassing is not prohibited, the friends of an individual case or two are tolerably certain to succeed at every election, but withal we observe at the head of the present list of the unsuccessful the names of those of the candidates recommended by the Committee, and whose success at the next election is almost certain.

From the Report we learn that the progress of the school and the tone of the boys is all that can be desired; the average of those among them presenting themselves for the usual examinations were successful; while the competition for the several scholarships awarded was close, and in every way gratifying to all concerned. Mr. France, with his usual generosity and praiseworthy desire to relieve the wants of others, for either the third or fourth time placed a free scholarship of the St. Ann's School at the disposal of the Council. The College itself is, we regret to find, greatly in need of funds; it is, therefore, very desirable that a large increase in the annual subscriptions should take place. An almost incredible fact was stated by a Governor at the meeting, that not more than ten per cent. of the parents of candidates for foundation scholarships avail themselves during their life-time of contributing to the support of this useful charity. This is not as it should be, since it betokens a greater lack of duty to themselves and their families than it does to their professional brethren.

The Royal College of Surgeons of England.

THE lecture arrangements for the present month at the Royal College of Surgeons of England include three discourses by Professor E. A. Schäfer, F.R.S., to be given on June 4th, 6th, and 9th. The subjects of these lectures are as follow:—1. The Functions of the Marginal Convolution. 2. The Analysis of Voluntary Muscular Action. 3. The Mechanism of Absorption. Six lectures on some important points in connection with the Surgery of the Urinary Organs will be delivered by Sir Henry Thompson, F.R.C.S., Professor of Surgery and Pathology to the College, in the theatre of the College, on Wednesdays, Fridays, and Mondays, commencing on Wednesday, June 11th, 1884. The following will be the subjects of these lectures:—Wednesday, June 11th.—Lecture 1. Introductory. On the Treatment of Stricture of the Urethra by Internal Urethrotomy. Friday, June 13th.—Lecture 2. On the Diagnosis of Urinary Diseases. Digital Exploration of the Bladder. Monday, June 16th.—Lecture 3. On Tumours of the Bladder; their nature, diagnosis, and treatment. Wednesday, June 18th.—Lecture 4. Impaired Vesical Function; its various forms and consequences. Friday, June 20th.—Lecture 5. The Progress of Operative Surgery for Stone during the present century: with the

most recent improvements in Lithotripsy, and their results. Monday, June 23rd.—Lecture 6. The results obtained by Lithotomy and Lithotripsy in Great Britain during the present century; with an analysis of more than 800 cases by the author, presented therewith.—Professor Schäfer's and Sir H. Thompson's lectures will, in every case, be delivered at 4 o'clock in the afternoon.

Death of Mr. J. Stannus Hughes.

We deeply regret to announce the demise of this eminent surgeon, who expired at his residence, Merrion Square, on Saturday evening last. Although latterly in rather failing health, no apprehension existed as to Mr. Hughes, who attended a meeting of the Council of the Royal College of Surgeons, of which he was Secretary, on Saturday afternoon, shortly after his return from which the fatal event occurred. The deceased was Surgeon to Jervis Street Hospital, and Professor of Surgery to the Royal College of Surgeons, and from his eminent social qualities as well as his professional ability, is much regretted.

Notification of Infectious Diseases.

THE Burgh Police and Health (Scotland) Bill, to which we recently called attention, because it proposes at one swoop to put every town in Scotland under compulsory notification, was the subject, last week, of a deputation to the Lord Advocate. He spoke as if the Bill was not likely to get a second reading this Session, and we fervently hope that his anticipation will be verified, but, if it does, he proposes to refer it to a select committee. Meanwhile, we are glad to learn that the Parliamentary Bill Committee of the British Medical Association has at length awakened to the existence of the measure, and that its Chairman has intimated to the Lord Advocate the opposition of the Association to the notification clauses.

It is to be hoped that this opposition will be something less of a sham than that shown by the Association to other similar Bills last year, and we advise the members of the Association to keep their own eyes on the action of the Committee. It is notorious that all the sympathies of the Committee are in supporting the compulsory notification, and that they have unwillingly entered an opposition because the Association ordered them to do so. If the Bill goes to a select committee, as the local Bills of last year did, at which all independent medical evidence was refused, and at which the British Medical Association made no attempt to obtain a hearing, there will certainly be a verdict against the profession.

The Discovery of the Circulation of the Blood.

DR. CHAPMAN, Professor in Jefferson Medical College, divides the discovery into six different stages—as follows:—1. The Structure and Functions of the Valves of the Heart, Erasistratus, B.C. 304. 2. The Arteries carry Blood during Life not Air, Galen, A.D. 165. 3. The Pulmonary Circulation, Servetus, 1553. 4. The Systemic Circulation, Cæsalpinus, 1593. 5. The Systemic and Pulmonic Circulation, Harvey, 1628. 6. The Capillaries, Malpighi, 1661.

The Examinations at the Irish University

THE following dates have been fixed for the summer medical examinations of this University: Degrees, Monday, June 23rd; Second Medicine, Tuesday, June 24th; First Medicine, Tuesday, July 1st. The first arts examination begins this year on September 2nd, nine days earlier than in 1883. The several examinations in the different faculties commence on September 15th; the medical is fixed for October 1st.

Health of Dublin.

LAST week's mortality in Dublin was the lowest, with one exception, since this time last year. The rate of mortality was 23.7 in every 1,000. There were only 15 deaths from zymotic diseases registered, being 10 under the number for the preceding week, and 12 under average of 10 years. There was but one case of typhus admitted to hospital, against 13 admissions during the preceding week, being 8 under the number in hospital on Saturday, 17th.

The City of the Cretins.

THE population of the village of Kokane, in Turkestan, is almost entirely composed of crétins and persons suffering from goitre. M. William Chapus, in his work on "The Doctors and Medicines of Central Asia," states that he has visited that town, and was quite astonished at the number of these unfortunates, some of whom were only slightly attacked, while others had a very large tumour. This is the only town in Turkestan in which the inhabitants possess this unpleasant privilege; such cases are rarely to be met with in other places. The town is situated on a plain 1,300 ft. high, and is abundantly supplied with water by a river coming down from the Aloï. In 1878, when the Russian troops were quartered there, more than half of them were attacked with goitre and sore throats after a few days, but iodine and subcutaneous injections cured them immediately. It has now been resolved to abandon Kokane, and to transport the population to Marghellone, the chief town of the province.

Lectures on Organic Chemistry.

A NEW course of lectures on Organic Chemistry has been commenced at the School of Pharmacy in Bloomsbury Square. They are given by Mr. Wyndham R. Dunstan, the Assistant Lecturer in Chemistry and Physics, and Demonstrator of Practical Chemistry. The design now carried into effect is founded on the recommendation of the Council of the Pharmaceutical Society in 1882, but the idea has not till now assumed any definite shape. The course is intended to afford a fundamental, connected, and systematic knowledge of the general facts of organic chemistry, as distinguished from a description of particular organic compounds considered separately in their application to pharmacy.

It is hoped that by such systematic instruction the educated pharmacist will be able to advise the medical profession upon the chemical relations of organic substances, their exact nature, and rational employment. The course will include an exposition of the modes of viewing the constitution of organic compounds adopted

at the present time, and of the principles involved in a systematic classification. In addition to this, special and detailed attention is devoted to those bodies which are of importance in medicine and the arts. A synoptical table has been compiled, and accompanies the printed syllabus as a comprehensive guide in considering the relations to each other of different classes of organic compounds. The course, which is numerously attended, is open to all students, and the lectures are delivered the first three mornings of the week.

The Value of "London University Distinctions."

GRADUATES of the University of London are wont to claim for their degrees an amount of consideration equal to, if not exceeding, that accorded to the degrees of any other University whatever. They will therefore be interested to learn the manner in which the Liverpool School Board apprise the acquirements the proof of which they estimate not unnaturally so highly. The authority in question is in need of an Assistant Science Demonstrator in connection with instruction in Mechanics and Domestic Economy, the salary offered being the magnificent one of £100 per annum, rising, in four years, to £120. The Board, however, has apparently been troubled with a suspicion that this figure might fail to attract the "one with experience of teaching, and practical knowledge of elementary physics and chemistry," for whom preference is expressed. Accordingly they advertise that, "if applicant holds Science and Art certificates and *London University distinctions*," they will generously allot him an *extra annual payment of £3 to £11*. We cannot conceive that any London graduate will be found to put so insultingly low a price upon his services and *distinctions*; but the Liverpool School Board evidently thinks there may be some who will be found to accept the terms advertised; and should it really be the case that this is so, it will prove that the Board authorities have formed a juster estimate of the University than that we entertain.

An Unhealthy Hospital.

SOME of our readers will remember the discussion and something warmer arising out of the alleged unsanitary condition of the then existing Lying-in Hospital, Liverpool. Infective disease made its appearance on many occasions amongst the patients, some died, and the institution was several times closed for disinfection. Its last closure was caused by an endemic infantile diarrhoea, accompanied by ulceration of intestines, commencing two or three days after birth with symptoms indistinguishable from thrush, and ending fatally in a short time, or if the little patients did not die off, continuing obstinately in spite of all treatment. It is not necessary to speak of the many efforts made to discover the cause and apply a remedy; it is sufficient to say that the building was at last sold to the Cancer and Skin Hospital authorities. After thorough cleaning, &c., and, moreover, after the hospital had been closed for a period of at least two years, work was again begun by the new management. It was not long, however, before infective disease again made its appearance, and cases did not do so well as it was anticipated and expected. The staff

were, however, on the alert, and, although our information on this head is not of the most exact description, we understand that the sewers were found defective, and sewer gas made its way freely into every part of the building. Things were then put right, discharge pipes were disconnected from the drains, and from this time the hospital has been as healthy as possible. The subject, we think, demands thorough investigation, in order that the blame, if any, should be laid on the right (or wrong?) parties.

The Physical Effects of Walking Matches.

WE do not seem in this country to have been as yet familiarised with the depressing effects produced in those who engage in lengthened pedestrian contests; nothing, indeed, which has hitherto been published in this connection presents any kind of similarity with the descriptions given in American lay papers of the state to which the winner of a recent match at New York was reduced. This unfortunate being might well excite pity in the pitiful. "His eyes were sluggish, bloodshot, and heavy, and encompassed by huge purple circles; his cheeks had so sunk in that the contour of his teeth could have been seen through them, and every movement was an illustration of acute agony; he swung his arms painfully; his head dropped on his chest; his shoulder-blade stuck out sharply from his attenuated body; his legs dragged lamely one after the other, and the muscles of his neck twitched nervously with every step." It is further added that the second prize winner in the same race was an Englishman whose appearance was even more pronounced than that of the American competitor, so that it is not possible to ascribe the pitiable condition of the latter to national causes. It only remains therefore to conclude that neither had duly prepared by training for the contest, and it would be improper to draw any important conclusion from the facts narrated.

DR. CAMERON, M.P., has obtained the first place in the House of Commons on July 1st, for a motion regarding small-pox in London. It is expected that Mr. P. A. Taylor will move an Amendment to the Resolution condemning the Vaccination Laws.

THE Council of the West London Medico-Chirurgical Society have instituted an annual lecture, to be called the "Cavendish Lecture." The first will be delivered on July 11th, at 8 p.m., by Mr. T. Holmes. The subject will be the "Medical Attendance on the Poor of London."

THE deaths registered last week in the principal large towns of the United Kingdom corresponded to an annual rate of 19.9 per 1,000 of their aggregate population. The death-rates in the several towns were:—Birkenhead 10; Bristol 14; Salford, Leicester 16; Huddersfield 17; London, Edinburgh, Wolverhampton, Bradford 18; Sheffield, Hull, Derby 19; Bolton, Birmingham, Sunderland; Liverpool, Brighton, Portsmouth 21; Leeds, Nottingham, Norwich, Cardiff 22; Dublin 23; Glasgow, Manchester, Newcastle-on-Tyne, Blackburn 25; Plymouth, Preston 27; Halifax, Oldham 28.

THE Annual General Meeting of the Irish Medical Association was held in the Royal College of Surgeons, Dublin, on Monday last, and was, in all respects, very successful. The attendance was large and representative, and the debates interesting. We print the report of the Council in our Supplement of this day, and hope to give a report of the meeting in our next.

THE election of the Council of the College of Surgeons of Ireland, held on Monday last, was very excited, a coalition having been formed between certain parties amongst the Fellows for the purpose of displacing some of the Councillors whose views they differed from. Upon scrutiny of the poll it was ascertained that Messrs. Stokes, Fitzgibbon, Carte, and Elliott had been placed on the Council in place of Messrs. Butcher and Denham, who had resigned, and Messrs. Macnamara and Thornley Stoker displaced.

Scotland.

[FROM OUR NORTHERN CORRESPONDENTS.]

EXTRAORDINARY CASE OF POISONING IN GLASGOW.—On the 25th ult. a peculiar case of poisoning was reported to the police of the western district, Glasgow, a whole family, consisting of a man and his wife and four children, having been taken seriously ill after partaking of some curds and cream obtained from a dairy. The persons affected were Hugh Martin, Mary Ann Bryden or Martin, his wife, and their family—Mary Ann, aged 18; Bella, aged 8; Clementina, aged 6; and the baby, James, aged 11 months. After partaking of some curds and cream obtained from the dairy of Janet Baxter they were all taken ill, suffering internal pains, vomiting, and showing all the symptoms of poisoning. The baby, who had only swallowed a couple of spoonfuls of the preparation, appeared to suffer as much as the others, which proves that the poison must have been of a very dangerous description. Dr. M'Phee, St. George's Road, was summoned to the house, and administered remedies, remaining with his patients for several hours; and it was not until morning before he considered them all out of danger. On the affair being reported to the police, a number of officers were instructed to inquire into the case. They visited Baxter's dairy, and learned that the milk from which the curds were prepared had been obtained by her from a dairyman named M'Leod. A portion of the curds and cream found in Martin's house and some of the milk found in Baxter's shop were taken possession of by the police, and, on the recommendation of Dr. Johnston, forwarded to Professor Dittmar, of Anderson's College, to be analysed.

GLASGOW SANITARY PROTECTION ASSOCIATION.—The quarterly meeting of the Council of this peculiar association was held last week, and it was reported that the Association continued to make progress, and promised, at the present rate of growth, to do a much larger amount of work, and have a larger membership than last year. The engineer was busy, as usual, inspecting and reporting on the sanitary condition of town houses; and the secretary mentioned, with regard to country houses, that they had already examined during the portion of the current year that had run as many as the total number last year.

EDINBURGH.—ANTI-VIVISECTIONIST MEETING.—A conference to consider the practice of vivisection, and to take steps to urge upon the Legislature the desirability of passing a law to suppress it, was held on Saturday, the 24th ult., in

Edinburgh, Rev. Dr. Adamson presiding. The attendance was small, and mostly ladies. The secretary intimated that a doctor in Ireland had left £3,000 to carry on the movement against vivisection. The will, however, was disputed, but a gentleman had intimated his readiness to pay any law expenses that might be necessary. Rev. Mr. Stewart, Aberdeen, moved that, in the opinion of the meeting, both humanity and religion are opposed to vivisection. Rev. C. E. Bowden, Edinburgh, seconded the motion, which was adopted. Another motion, proposed by Dr. Bowie and seconded by Rev. Mr. Henderson, that "vivisection as a method of investigation is erroneous in theory, misleading in practice, and ought to be suppressed," was met by an amendment, proposed by a medical student, to the effect that vivisection had been of use, and would be of greater utility to the country. The amendment was not seconded, and the motion was carried. Votes of thanks terminated the proceedings.

WHAT IS MEDICAL ADVERTISING?

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—The entertaining discussion in progress in your paper respecting the proper limits of professional advertisement has afforded me a good deal of amusement and, I trust, instruction. It is most refreshing to find not only one or two, but three, four, and even five gentlemen openly avowing that they do not worship mammon in the blind spirit of idolatry shown by those who cry their virtues and their books in the columns of the daily press. By-and-by, should the principle of separation evident in recent controversy continue to work its effect, it will be incumbent on the Council to publish annually *two* "Registers," one of those practitioners whose first regard is for their profession, and the other of those whose chief care is "No. 1." It might advance matters a little if that guardian of our morals, the Royal College of Physicians, would kindly issue a list of its Fellows, distinguishing those who, either by virtue of their official position in the College or because of their status *out* of it, are permitted to advertise themselves *cum laude*, the remainder on the list being, of course, made scapegoats for the sins of their more powerful fellow Fellows. The whole question is a most bewildering one, and seems to be sadly mixed. On one side I see a president of a Royal College placarded by name all over the world as a skin doctor; while on the other I see a miserable hand-to-mouth existing general practitioner chivied from corner to post because his too generous friends have given him the benefit of a paragraph in a country paper with at most a few hundred readers. Why is not the ex-president bullied in a similar manner? The answer is very plain, and it is, because we are all of us at heart insincere in this particular. Mr. Editor, do you commence a modern crusade against humbug? Preach the doctrine "advertise everywhere, anywhere, anyhow." Let the ruling principle of nature have free play; and let him who advertises most and best oust his more diffident or less vociferous neighbour. Either this, or more attractive perhaps, though less hopeful, let the College of Physicians throw aside its miserable pretence of shame and utter boldly forth its condemnation of unprofessional conduct and dishonourable dealings on the part of *any* of its dependents. What matter if it must, so doing, sacrifice one or more of its own executive? What pity can be felt for those who determinedly outrage the regulations they have helped to frame, and who feel no compunction in constantly and openly defying them. Let it be, advertise one advertise all; or else let the sickening cant about violated pledges for ever cease to be heard, especially from the invertebrate judges who quail before the powerful and castigate the weak and feeble.

Yours, &c.,

ANABLEPS.

PROPOSED CHANGES AT DURHAM UNIVERSITY.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—The letters which have appeared in the medical

papers during the past few weeks concerning the proposed change in the regulations for the degree of M.D. of the University of Durham for practitioners of 15 years' standing have created a very strong feeling among the graduates and undergraduates, which culminated in a crowded meeting, held at the infirmary on the 16th ult., Charles Green, M.D. Durham, Medical Officer of Health for Gateshead, in the chair, at which the following resolutions were unanimously passed:—

1. That this meeting hears with great dissatisfaction that there is in preparation a memorial praying the Senate of the University of Durham to alter existing regulations concerning the degree of M.D. for practitioners of 15 years' standing.

2. That this meeting is of opinion that the proposed alterations would greatly detract from the value of the degree as obtained in the usual course.

3. That the degree of M.D. obtained by other than the usual course—viz., that of putting in residence, attendance on lectures, and the passing of the several examinations—is prejudicial alike to the interests of the University of Durham and to the status of those who have obtained the degree in the orthodox manner.

4. That an humble petition be prepared to present to the Senate, praying it, not only to neglect the memorial suggesting the afore-mentioned proposed alterations, but also very earnestly praying it to consider the advisability of abolishing the degree of M.D. for practitioners of 15 years' standing.

5. That an account of the proceedings of this meeting, with the resolutions passed, be sent to the medical journals for publication.

A small committee was formed, of which Dr. Green was elected chairman, for the purpose of drawing up a petition in accordance with the above resolutions.

A circular letter is about to be sent to all graduates in Medicine of the University of Durham, other than those who have obtained the M.D. for practitioners of 15 years' standing, whose addresses appear in this year's "Medical Directory."

We shall also be glad if those whose addresses do not appear will communicate with us *at once*, as we are anxious that no time shall be lost.

We are, Sir, your obedient servants,

J. A. HUTCHINSON, M.B., M.R.O.S.,
C. POPE WALKER, M.R.C.S.,
Hon. Secretaries.

University of Durham College of Medicine,
Newcastle-on-Tyne.

DR. MORE MADDEN ON THE INCREASE OF LUNACY.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—When a writer puts forward a startling theory it is important to test both his own mental capacity as an accurate thinker and the data from which he deduces his conclusions. Let us rigorously test both the writer and his data in this particular instance.

1. Dr. Madden states that in 1800 there was only one lunatic to 7,300 of the population, that is about 1,500 in all England. In six years after there were 2,248; in thirteen years, 6,000; in four years again 6,000; in three years, 14,000. Surely no accurate thinker would conclude that these variations in the estimates were due to actual variations in the numbers of lunatics.

2. Turning to the explanation given of the causes of the increase of insanity, they are *increase of drinking* among all classes of society, *growing luxuriousness* of youths, *forced education* generally, and especially *misdirected education of women*. Now, except the first of these evils, it is manifest that only a very fractional portion of the population are affected by such influences. How many of the thirty millions in England are living too luxuriously, or working too hard for Civil Service examinations, or engaging too earnestly in business? Evidently, to prove anything like this, it must be shown in what proportion the increase in insanity has fallen on the different classes in society, both in respect to their occupation and their physical surroundings. Again, it appears that there are more lunatics in Ireland, in proportion to the population, than in England. Yet Irishmen drink far less liquor than Englishmen, and neither over-education nor excessive diligence in business are generally put down among the ills of Ireland—still less that its women are becoming blue-stockings by the million. Again,

I fear Dr. Madden does not come out well as an accurate thinker or reasoner.

3. If Dr. Madden's figures prove anything, they prove that the appointment of Her Majesty's Commissioners of Lunacy had more to do with the increase in lunacy than anything else. There is no question about the *post hoc*, at all events. Lunacy has doubled under their régime. Whether they set men—and especially women—mad, or whether they only found out the lunatics does not appear. Dr. Madden himself admits that people are put in asylums now who would not have been a few years ago. If along with this there has been a decrease in the mortality among lunatics a part at least of the increase of the number of lunatics would be accounted for. I have no special experience in matters connected with lunacy, but I can recognise inconclusive reasoning when I meet with it, and I think I have shown that Dr. Madden has given a notable example of it. Judging from my own small experience I should say that poverty, hardship, and exposure are very potent factors in the production of insanity, and I believe that the source of any real increase in insanity is to be sought for mainly in the condition of the lapsed masses in cities. No doubt a careful analysis of the previous life history of the insane would throw much light on the subject, but I fear the material is not accessible.

While criticising Dr. Madden's figures thus sharply I would fully endorse what he says about the importance of having the treatment of the insane under the supervision of "all round physicians" who can recognise a diseased stomach or uterus as a cause of insanity, and the equal importance of having the committal of the insane entrusted to men who have considerably greater fitness for such a responsible duty than the "legal qualification."

Yours, &c.,

A. W. WALLACE, M.D.

THE DUBLIN TRADE IN DISEASED MEAT.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—I am very glad to see that you are taking up this question and so ably discussing it. I cannot agree with you, however, that we make a profit by the sale of these diseased carcasses, our nett loss is nearly £4,500 a year for the last six years. Of course if we only received 15s. a head from the knacker for all the beasts, our loss would be enormously increased, but profit there is none. Again, why do you insist that we sell the meat to the poor, I maintain that you and I have just as good a chance of getting our share of it, we deal with a contractor who disposes of it to the butchers. I allow that he may make a splendid profit. Some years ago when the majority of the guardians decided that our paupers in the unions should not be fed on this meat, which, however, they considered good enough for the general public, a good opportunity was lost for deciding at once and for ever the question as to its wholesomeness. If the paupers thrive on it then it is good for food, but if a plentiful crop of carbuncles, phlegmons, and other such unholly fruit appeared, then let all lung diseased cattle be cremated. As to the medical aspect of the question I have nothing to say, let the doctors fight that out. I am only recently a member of the Cattle Diseases Committee and cannot say how long this disgusting traffic, as you term it, has gone on, but suppose medical opinions were taken as to the digestibility, &c., of the diseased meat and the sanction of the authorities was obtained before the guardians began it, I think your strictures would be directed against these parties and not against the unfortunate guardians who, sorely against their will, are obliged to carry out the provisions of this Contagious Diseases (Animals) Act, and to apply £4,000 or £5,000 a year out of the poor rates in such a useless and thankless manner.

The subject is a most proper one for the medical press to ventilate, but I wish it would devote some of the superfluous energy expended in reforming the Poor-law guardians towards pointing out some tangible means of prevention or cure of this pleuro-pneumonia. I wish also the general press would take up my side of the question—viz., this enormous expenditure of the ratepayers' money in purchasing these diseased animals in the vain hope of stamping out the disease by their slaughter and by bringing public opinion thoroughly to bear on it, so influence all those who should be interested in the matter that they would no longer passively endure the state

of things which has gone on so long, but energetically seek and carry out a remedy. Meanwhile, as long as our present system of trusting the constitutions and lives of the citizens of Dublin to the mercies of two veterinarians and accustoming our stomachs to digest irritant poisons at their discretion, as long as we pay dairymen a premium for lung-diseased cattle, and inspectors a good salary for discovering them, so long will the farce go on until, in process of time, we may have in Dublin a reproduction of the sixth plague of Egypt.

Yours, &c.,

WM. DOMVILLE HANDCOCK, J.P., P.L.G., S.D., &c.

[As we have already said, we feel fully justified in accusing the guardians of making a profit by the iniquitous traffic in diseased meat in which they are engaged. The knacker's price of this carrion for boiling down is 15s.; the butcher's price is £5; so that, clearly, the guardians make £4 5s. by selling to the latter.

When this traffic was initiated a medico-sanitary inquiry was held, and a report was made by Dr. MacCabe to the Privy Council; we believe that that report unhesitatingly condemned the proposal to sell any of the pleuro-pneumonic meat for food except that of cattle who had just shown symptoms of the disease.

That report was suppressed by the authorities, and this disgraceful trade entered upon in spite of the warnings of Dr. MacCabe and others. We believe that the law, the guardians, the Local Government Board, and the Irish Privy Council, are one and all to blame in the matter. The law offers a premium to the farmer to pass off all the unsaleable cattle he has as pleuro-pneumonic, for it awards him a compensation amounting to three-fourths of the fancy price of the animal—which three-fourths is usually in excess of the real price. The guardians seem to keep no sufficient control over their inspector, who, if he were disposed to do a job for the benefit of the farmer, is in a position to do so.

The Local Government Board passes the accounts for these compensations, and the amounts which the guardians receive for the fevered carrion, through the hand of its auditors, and yet never remonstrates either against the monstrous outlay or the abominable traffic, and the Privy Council gives its authority for the continuance of the trade.

We note that Mr. Gray, M.P., has elicited from the representative of the Privy Council the official statement that he "is happy to say that the sale of pleuro-pneumonic meat is not permitted in England." We earnestly trust that Mr. Gray, recollecting that the largest proportion of this stuff goes to the low-class butchers for consumption by the poor, will persevere in his praiseworthy attempt to put a stop to it. If he need evidence of the extent of it he will find it in the report of the Medical Officer of Health for Dublin, from which it appears that no less than 8 tons of diseased meat were seized by the corporate authorities within the month, nearly 7 tons of which consisted of "guardians" beef. —ED.]

Royal College of Physicians of London.—At an extraordinary meeting of the Council of this College, held on Thursday last, Sir W. Jenner, Bart., K.C.B., President, in the chair, the following business was transacted:—Replies to the addresses of condolence passed by the College were read from Her Majesty the Queen and H.R.H. the Duchess of Albany. A proposal from Dr. Alexander Tweedie to present his portrait to the College was read and was cordially accepted. A memorandum from the Royal College of Surgeons relating to the manner in which it is proposed in the Medical Acts Amendment Bill to dispose of the surplus funds of the Medical Boards was referred to the Medical Bills Committee. Mr. John Bland Sutton, the Murchison Scholar, was presented and congratulated on his success. The election of Fellows was adjourned, the list of the nominees being referred to the Council for further consideration.

Dr. Dyce Duckworth was unanimously elected treasurer of the College in the room of the late Dr. Whyte Barclay. A report was read from the Nomenclature Committee, which has completed its labours, and thanks were voted to the Committee. The following addition to the Bye-laws was proposed for the first time, and carried:—"1. The President shall appoint annually, from among those Fellows of the College who have filled the office of Senior Censor, two Fellows as Vice-Presidents, who shall hold office for one year, and not be re-eligible until after the lapse of five years. 2. In case of the unavoidable absence of the President, or of his inability to act, one of the Vice-Presidents shall, for the purpose of transacting routine business and on all matters of form, act as his Vicarius. 3. The Vice-Presidents, on taking office, shall give their faith to the Fellows, using the following words:—"I give my faith that I will discharge faithfully the duties entrusted to me as Vice-President." On the report of the Council being presented, with a list of sixteen Members nominated for election as Fellows, the following was moved and adopted:—"That the list of Members nominated by the Council and proposed to the College for election to the Fellowship, be referred back to the Council for re-consideration, with full power to insert fresh and to remove existing names, provided that the total number of nominations do not exceed twelve."

Royal College of Physicians of London.—The following candidates, having undergone the necessary examinations, were admitted Licentiates on Thursday, May 29th:—

Deane, Arthur Cecil, 40 Bassett Park Road, W.
De Morini, William Raoul, St. Bartholomew's Hospital, E.C.
Maitland, Percy Edmund, 12 Albert Street, N.W.

Royal College of Surgeons of England.—The following has just been announced by the Council of this College as the subject for the Collegiate Triennial Prize:—"The Nature of Inhibitory Action in the Animal Body to be elucidated by Original Research." This prize consists of the John Hunter Medal, executed in gold to the value of fifty guineas, or, at the option of the successful author of the dissertation, of the said medal executed in bronze, with an honorarium of fifty pounds. Essays for this prize must be sent in on or before Thursday, December 31st, 1885. The following are the subjects for the Jacksonian Prize of this and the succeeding year:—"The Surgical Treatment of Uterine Tumours, both Innocent and Malignant," and "The Diagnosis and Treatment of such Affections of the Kidney as are amenable to Direct Surgical Interference." The value of these latter prizes is the amount of the dividend (between £12 and £13) received from the Trust.

Royal College of Surgeons of Ireland.—The undermentioned candidates, having passed the necessary examination, were admitted Licentiates of the College during the May meetings of the Examiners:—

Berkeley, J. Acheson.
Bagot, George A.
Bate, Louis A. F.
Bernal, John.
Carte, Francis L.
Collins, James V.
Cronin, Cecil.
Crow, T.
Cuffe, Alexander.
Daly, Thomas J.
Delaney, Julius Barry.
Dillon, Thomas L.
Eccles, Cuthbert.
Ford, Patrick J.
Greig, Frederick J.
Hanna, James.
Kennedy, Denis.
Kennedy, Graham.
Kilkelly, Charles E.
Lane, Benjamin.

Lawson, Frederick D.
Lowney, John.
McNulty, Edward.
McGrath, Thomas J.
Maguire, James H.
Minchin, E. L.
Moloney, Cornelius R.
Murray, Walter A.
Nash, Llewellyn J. M.
Perrott, Charles J.
Scott, William W.
Smart, Edward N.
Stewart, Alexander.
Thomson, Malcolm E.
Westropp, Augustus M.
Wright, H. E. P.
Wright, Thomas N.
Woods, John H.
Yates, John F.

Thirty-nine candidates passed, and thirteen were stopped. Seventy-one gentlemen passed the first half of their examination for the licence, and thirty-six were stopped.

University of Cambridge.—At a congregation holden on Thursday last, May 29th, it was agreed, on the recommendation of the Special Board for Medicine, that any person who had taken the degree of Master of Arts before February 27th, 1882, and done all that is required by the statutes and ordinances of the University for admission to the degree of Bachelor of Surgery may be admitted to the examination for the degree of Master of Surgery. At the same Court the undermentioned degrees were conferred:—*Doctor of Medicine.*—Alfred Francis Street, Trinity College. *Doctors in Science.*—William Johnson Solias, St. John's; John Venn, Caius. *Bachelor in Medicine.*—George Henklots Vos, Christ's. *Bachelor in Surgery.*—Geo. Lindsay Johnson, Caius.

Notices to Correspondents.

✎ CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a *distinctive signature or initials*, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

DR. DUTIL (Paris).—With pleasure.

DR. WOJNARSKI (Ballarat) is thanked. Interesting information from the Colonies is always acceptable.

SALIVATION.

To the Editor of the MEDICAL PRESS AND CIRCULAR.

SIR,—A similar case to that described by "Myosotis" in your last issue came under my notice some three years ago; various remedies had been ineffectually tried. The patient was a female, and had suffered for years. Atropia, used hypodermically, was resorted to, with complete success, 1-240 gr. was given, gradually increased to 1-80 gr. I should be glad to learn the result of this treatment in the present instance.

Yours, &c.,

CHARLES FREDERICK KNIGHT, M.D.

82 Harcourt Street, Dublin.

NITRO-GLYCERINE AS A MEDICINAL AGENT.

To the Editor of the MEDICAL PRESS AND CIRCULAR.

SIR,—It is strange that Dr. J. McGrigor Croft has not till now heard of the medicinal uses of nitro-glycerine. It was introduced into medical practice in 1819, by Dr. Herring, of Philadelphia, under the name of glonorin, and since that time has been largely used in the homoeopathic school, chiefly for congestive headaches of a peculiar sort, and some forms of neuralgia. Last year a monograph on its uses in angina pectoris, with numerous cases, by Dr. Murrell, was published, and these nitro-glycerine lozenges have been advertised for some time past. There is not much fear of its action being cumulative, and thus causing death by explosion, for its action is very short, and after a dose strong enough to cause intense headache, in an hour or little more the symptoms are all gone.

Yours, &c.,

R. E. DUDGEON, M.D.

58 Montagu Square, London,
May 28, 1884.

To the Editor of the MEDICAL PRESS AND CIRCULAR.

SIR,—If Dr. McGrigor Croft will consult the number for 1st April last of the *Journal of the University of Philadelphia*, edited by the notorious Dr. Buchanan, he will read of a patient exploding through an over-dose of nitro-glycerine, the roof being lifted clean off the house, and the nurse in attendance was found sticking in the chimney.

Yours, &c.,
CYNIO.

[Nitro-glycerine, otherwise glonorin, has been in extensive use since 1858, and Martindale's pills and lozenges containing it have been well known for the last five or six years. Our correspondent would find references to it in the "Medical Digest," and instances of its frequent employment have been recorded from time to time in the various medical journals. There is no fear of cumulative disasters, nor an exhibition in this country of a like character to that referred to by our correspondent "Cynio."—ED.]

SOCIETY FOR RELIEF OF WIDOWS AND ORPHANS OF MEDICAL MEN.—We are asked to state that a quarterly court of this Society will be held on July 9, for the purpose of electing appropriate candidates to its benefits. Members of the profession wishing to be balloted into the Society must send in their names to the Secretary before June 17.

MR. W. B. (Wigan) and M.D. LOND.—On account of the public holidays your communications did not reach us in time for the present issue.

The Societies, College Lectures, &c.

WEDNESDAY, JUNE 4TH.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—At 4 p.m., Mr. Edward Albert Schäfer, The Functions of the Marginal Convolution.

OBSTETRICAL SOCIETY OF LONDON.—At 8 p.m., Specimens will be shown by Dr. Godson, Dr. Galabin, Dr. Aveling, Dr. Walters, Dr. Mallins, Dr. John Williams, and Dr. R. Barnes. Dr. Playfair, Note on the Absorption, with ultimate recovery, of Thrombosis of the Pulmonary Artery in the Puerperal State.—Dr. Matthews Duncan, On Fetal Revolutions.—Dr. Lediard, Fibro-cystic Myoma of Uterus.

THURSDAY, JUNE 5TH.

OPHTHALMOLOGICAL SOCIETY OF THE UNITED KINGDOM.—At 8 p.m., Dr. F. H. Miles, Drawing of Fundus with Choroidal Tubercles; Stained Sections of Tuberculous Choroid.—Dr. Bralley, (1) Paralysis of External Rectus and Mydriasis, with a recent history of Unilateral Diplopia. (2) Sympathetic Papillitis.—Messrs. Critchett and Juler, Case of Choroiditis Disseminata.—Messrs. Cowell and Juler, Mounted Specimens of Intra-ocular Sarcoma.—Dr. Sharkey and Mr. J. B. Lawford, Optic Neuritis associated with Acute Myelitis.—Mr. Nettleship, (1) Cases of Recovery from Amaurosis in Infants. (2) Cases of Retro-ocular Neuritis.—Dr. C. E. Fitzgerald, An Instrument for showing the Action of the Accommodation.—Mr. J. B. Lawford, Amblyopia with Contraction of Visual Fields and Central Scotoma, ending in recovery.—Mr. Adams Frost, Ciliary Staphyloma following Irdochoroiditis, sympathetic ophthalmitis subsequent to excision.—Mr. Sims in Snell, Case of Unilateral Diplopia.

FRIDAY, JUNE 6TH.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—At 4 p.m., Mr. Edward Albert Schäfer, The Analysis of Voluntary Muscular Action.

ROYAL INSTITUTION.—At 8 p.m., Mr. Willoughby Smith, Electric Induction Experiments.

SATURDAY, JUNE 7TH

ROYAL INSTITUTION.—At 8 p.m., Professor Bonney, Microscopical Geology.

MONDAY, JUNE 9TH.

ODONTOLOGICAL SOCIETY OF GREAT BRITAIN.—At 8 p.m., Casual Communications by Messrs. W. St. George Elliott, W. E. Harding, David Hepburn, &c. Mr. Oakley Coles, On the Maintenance of Health amongst the Practitioners of Dental Surgery.

TUESDAY, JUNE 10TH.

SOCIETY FOR THE STUDY AND CURE OF INEBRIETY.—At 4 p.m., Papers: Dr. W. B. Carpenter, On the Causation, Physical and Moral, of Inebriety.—Mr. Axel Gustafson, On Inebriety and Volition.

Vacancies.

Brompton Consumption Hospital.—Resident Clinical Assistant. Applications, testimonials, &c., to be sent in to the Secretary before June 14. (See advt.)
Burton-on-Trent Infirmary.—House Surgeon. Salary commencing at £180, with furnished rooms. Applications to the Hon. Sec. before June 12.
Owens College, Manchester.—Lectureship in Dental Surgery. Applications to the Registrar before June 16. (See advt.)
Queen's College, Birmingham.—Professorship of Anatomy. Stipend is £262 10s. Applications to the Secretary by June 30.
St. Mary's Hospital, Paddington.—Medical Superintendent. Salary, £150, with board and residence. Applications to the Secretary before June 10.

Appointments.

CAIGER, F. F., M.B., M.S., M.R.C.S., L.R.C.P., House Surgeon to St. Thomas's Hospital.
COOPER, G. F., M.R.C.S., L.R.C.P., House Surgeon to St. Thomas's Hospital.
GRANT, H. L., M.B., Assistant Medical Officer to the Buckingham County Asylum, Stone, near Aylesbury.
GREEN, C. D., M.R.C.S., L.R.C.P., Resident House Physician to St. Thomas's Hospital.
HEBERT, C. A., M.R.C.P. Lond., Demonstrator of Anatomy in the Westminster Hospital Medical School.
HULL, W., M.B., M.R.C.S., L.R.C.P., Resident House Physician to St. Thomas's Hospital.
JOHNSTON, G. D., M.R.C.S., L.R.C.P., House Surgeon to St. Thomas's Hospital.
LEVINGE, E. G., M.B. Dub., L.R.C.S.I., Resident Medical Superintendent to Mount View Lunatic Asylum, Wellington, New Zealand.
ROBINSON, H. B., M.R.C.S., L.R.C.P., Assistant House Surgeon to St. Thomas's Hospital.
SANEYOSHI, Y., M.R.C.S., L.R.C.P., Assistant House Physician to St. Thomas's Hospital.
SCOTT, T., M.R.C.S., L.R.C.P., Assistant House Physician to St. Thomas's Hospital.
SMITH, F. W., L.R.C.P. Lond., M.R.C.S., Medical Officer to St. George's Workhouse, Southwark.
STEVENS, F. J., M.R.C.S., Medical Officer for the Kilburn District of the Thirak Union.
STONE, F. W. S., M.R.C.S., L.R.C.P., Non-resident House Physician to St. Thomas's Hospital.
SUTTON, S. W., M.D., B.S., &c., Ophthalmic Assistant to St. Thomas's Hospital.

Births.

BODINGTON.—May 26, at Ashwood House, Kingswinford, Staffordshire, the wife of G. F. Bodington, M.D., of a son.
HALL.—May 24, at Silvermines, the wife of J. H. Andrews Hall, L.K.Q.C.P.I., of a daughter.
KINKAD.—May 27, at West House, Galway, the wife of E. J. Kinkad, M.D., of a daughter.
MOYMAN.—May 25, at Loughton House, Newport, Monmouth, the wife of E. M. Moyman, M.D., of a son.
WOODHOUSE.—May 27, at 80 Upper Merrion Street, Dublin, the wife of Stewart Woodhouse, M.A., M.D., of a son.

Marriages.

DUKE—RUCKER.—May 27, at St. James', Clapham Park, Edgar Duke, M.R.C.S., of Freshwater, I.W., to Adela, youngest daughter of D. H. Rucker, Esq., of Errington, Clapham Park.
RYLEY—MEADOWS.—May 27, at St. Mary Abbott's, Kensington, James Ryley, M.D., of Great Yarmouth, to Mary Grace, eldest daughter of M. W. H. Meadows, B. Matthews's, Ipswich.

Deaths.

ALDRED.—May 21, in Hyde Park, suddenly, H. Allen Aldred, M.D., of Westbourne Park.
ALDRIDGE.—May 22, at Shirley House, Dorchester, John Peck Aldridge, M.D. & J.P., aged 71.
CUFAUDE.—May 24, at his residence, Acle, Norfolk, William Henry Cufaupe, M.R.C.S. Eng., L.S.A.
FINCH.—May 28, at Pau, Basses Pyrénées, France, Frederick Cotter Finch, M.D., late of Blackheath, Kent, aged 70.
TWEEDIE.—May 20, at Bute Lodge, Twickenham, Alexander Tweedie, M.D., F.R.S., late of Brook Street, London, aged 79.

ANTISEPTIC INHALATION AND THE BEST METHOD OF CONDUCTING IT. (a)

By ROBT. J. LEE, M.A., M.D. Cantab., F.R.C.P. Lond., Late Lecturer on Pathology and Forensic Medicine, Westminster Hospital, and Joint Lecturer on Obstetric Medicine, St. George's Hospital.

It was not difficult to foresee that if the antiseptic principle of treating certain surgical forms of disease were once established upon a sound clinical basis, it would be soon extended to the treatment of diseases of the lungs, and particularly of the most common disease, pulmonary phthisis. Before this could be done, however, we had to consider carefully the different conditions under which the treatment could be carried out. It was easy to use a fluid antiseptic where the parts were within reach, but in the case of the lungs it was clearly necessary to use the antiseptic in the form of vapour, so that it could be carried by inspiration into contact with diseased tissues.

The bacillus theory of phthisis rather favoured the use of antiseptic agents, and thus encouragement was given to this extension of a principle, at first applied only in surgery, but promising very reasonably to be of value, and great value, to the physician. It must be distinctly admitted, I think, that the merits of this method of treatment will be determined entirely by clinical experience. I mean to say that if it is to be a matter of faith with the great number of us, it will depend on our own personal observations and our own experiments; and however reasonable it may be in theory, we should soon cease to adopt it if, after a few trials, we met with doubtful or negative results. It matters very little to the majority of our profession whether the bacillus theory of tubercle be decided one way or the other, and only those few can feel much interest in the question who are competent to examine it for themselves. But the majority of our profession cannot do this. The knowledge and skill required

to test microscopically or otherwise the nature of a bacillus or bacterium are very considerable; and the most experienced microscopical examiners are the most aware of the difficulties of this kind of investigation.

But we can put to the test the value of the antiseptic principle in practice, and it is not only our duty to do so, each one for himself, but the promise held out of benefit to those that suffer is so great that our liveliest interest must be excited by it.

The question, therefore, that we must first decide is briefly this. The antiseptic agent which we propose to employ must be in the form of vapour, and not of fluid. This vapour must be tested in some way, and shown to be reliable. It must be tested just as we should test a fluid before using it. It will not do to be making experiments with an agent the qualities of which we are ignorant of, for self-evident reasons; but particularly because we could not bring into harmony with our own observations those of others who had obtained different results. We must at the very outset settle this question first, and when we are agreed on the plan we intend to follow, we shall soon be able to establish conclusions. You would imagine that this preliminary question must have been decided already. This is not the case, however, and it still remains to be considered.

I will point out as briefly as possible the method that appears to me to be altogether the most convenient, the most reliable, and the most accurate.

I have here a solution of carbolic acid in water, such a solution as could be relied upon for surgical practice; the ratio of carbolic acid to water is 2 per cent.; that is, one in fifty. Now if we convert this solution into the form of spray some might suppose that it could be inhaled. This spray, however, is not vapour. The particles of fluid have not changed their condition except that they are separated or pulverised. They are still in the fluid state, and they act as the fluid itself would act on parts they come in contact with; but it would be easy to show that they cannot pass far into the respiratory passages, and cannot reach the remote parts of the lung.

(a) Read before the West London Medico-Chirurgical Society.

The agent or force by which bodies are generally converted from the solid or fluid state to that of vapour is heat; and if we heat or boil this fluid and convert it into vapour we shall discover that the carbolic acid also evaporates, and we may naturally inquire, what are the properties of this carbolic vapour. Is it in the first place a vapour of definite strength, or does the carbolic acid only come off in small quantity? Is it antiseptic vapour?—that is, will it prevent septic action? and lastly, can it be inhaled? and can we reasonably expect it to act as an antiseptic in phthisis and other forms of disease of the lungs? On these points I have made experiments which would satisfy you, if I had time to enter into details, that there is no method so convenient and reliable as this very simple one of heating an aqueous solution of carbolic acid and breathing the vapour of it. There is one reason for this to which I would ask particular attention, and after explaining it, if time allows, I will make a few remarks on the use of some agents, such as benzoic acid, thymol, and others, which might possibly be useful in therapeutics.

Our first object being to obtain an antiseptic vapour of definite strength; when it was observed, I believe by myself for the first time, that carbolic acid apparently evaporated at the same rate as the water with which it was mixed, it was clear that we had thus presented to our use the most simple and accurate means of testing this question. When I say that vapour of carbolic acid appeared to come off equally with the water, you will understand that I was using the only tests which I could apply personally, and that this observation arose, not by accident, but as the result of a series of experiments made with several substances, of which the volatile oils were the most important—the oils of turpentine, eucalyptus, cloves, cubebs, cinnamon, and many others, the experiments being made simply to determine this question of how they acted when boiled with water. There were no data to assist; as you can easily understand, this question would not offer much attraction to any one but a medical practitioner who had a special object in view. Having found that none of the substances had this peculiar property of carbolic acid, I felt impressed with the importance of submitting my own results to further experiment conducted by scientific chemists. It appeared to me most necessary that there should be no mistake upon this point, and I must take advantage of this opportunity to express my obligations to Dr. Piesse, and Mr. Johnston, for the care and trouble they took in deciding a question of some difficulty in chemical analysis.

The determination of the quantity of carbolic acid in a given solution is not a very easy matter. What was done was this: A certain measured quantity of water was taken, and to this a certain definite quantity of pure carbolic acid was added. This was boiled until a certain quantity of the solution had evaporated, and the remainder was then tested. Again, another quantity was evaporated and the remainder tested in the same way as before; and this operation was repeated until the solution had been entirely used. It was thus easy to determine whether the carbolic acid kept a constant proportion to the water or not. It is known to chemists that hydrochloric acid mixed with water evaporates in constant ratio, a fact observed, I believe, by Professor Roscoe.

The experiments of Dr. Piesse and Mr. Johnston were entirely confirmatory of those I had made in a different manner, so that now I am in a position to assert that for the purposes of testing the antiseptic method in the treatment of pulmonary disorder we have a reliable, accurate, and convenient plan at our disposal.

I will read to you the letter in which Dr. Piesse states the results of his experiments:—

“January 1, 1884.

“The experiments consisted of three sets, each of six experiments.

“The strength of the solution of carbolic acid in Set 1 was 5 per cent.; in Set 2, $2\frac{1}{2}$ per cent.; in Set 3, 0.5 ($\frac{1}{2}$) per cent.

“The *modus operandi* was as follows:—

“Six flasks were taken, numbered 1 to 6, and into each a solution containing 10 grammes (150 grains) of pure crystallised carbolic acid (absolute phenol) was poured, and the bulk of fluid made up to 200 centimetres by the addition of distilled water. They were then set to boil, and were boiled vigorously—

“No. 1 for 10 minutes

“2 „ 20 „

“3 „ 30 „

“4 „ 40 „

“5 „ 50 „

“6 „ 60 „ respectively.

In each, after cooling and restoring to its original bulk with distilled water, the amount of phenol remaining was estimated by pouring in a standardised solution of hypobromate of soda, containing a trace of free bromine.”

Then follow the actual figures in a tabular form, from which it will be clear when we consider the nature of this analysis that for practical purposes the vapour is constant in its quality. I will not trouble you with these figures as they would more suitably be submitted in a printed form.

The next question which arises is this, What proportion of carbolic acid and water should be used to afford a vapour of certain value as an antiseptic, in which the carbolic acid is reduced to a minimum? for there is clearly a disadvantage in using a vapour stronger than necessary; or, worse than that, injurious effects might follow from it.

If the solution contains carbolic acid in the proportion of 1 to 80 as the strongest, and from that to 1 in 150, we can be certain of obtaining a vapour of high antiseptic properties. A vapour stronger than 1 in 80 acts as a solution would upon the skin and produces the usual irritating effects which follow the application of carbolic acid. A drachm of carbolic acid, that which is known as Calvert's No. 2, added to from fourteen to sixteen ounces of water, will be found to supply a vapour of proper qualities for the purposes required.

I would suggest now a simple plan by which the vapour can be exhaled. Instead of boiling the solution in a small vessel or in a kettle from which the steam would pass off at a high temperature, and thus considerable danger might arise of accidental scalding of the mouth or throat, the steam may be made to issue in a jet at a certain tension. As the steam in this state escapes it carries with it a current of air which quickly reduces its temperature, and reduces very considerably the possibility of the danger arising from the use of vapour at low tension.

Some years ago I explained the use of this principle for the supply of warm vapour, as distinguished from steam at high temperature. By the addition to our knowledge of the property of carbolic acid which I have been pointing out, we obtain a current of antiseptic vapour, and we obtain it in such a form that we can use it very conveniently for the purposes of testing clinically the value of the antiseptic theory in the treatment of pulmonary disorders.

It has been thought by some that the best plan would be to place the patient in a room the air of which was charged with the vapour of carbolic acid, and theoretically this plan has much to be said in its favour; but I need hardly point out that such a plan must be so greatly limited in its application as to make its general adoption quite impossible. It has no advantage practically over the plan I have suggested, and as the chief object of my remarks is to provide a very simple and ready means of applying the antiseptic principle in daily practice, I shall make no further observations upon the advantages or disadvantages of the carbolic room.

Now, if you ask the question, What proof is there that the vapour or steam given off by water and carbolic acid when boiled together in the proportions I have stated is surely antiseptic? the answer is simply this, that by experimentally exposing to its action solutions which under ordinary circumstances are found to putrefy, such putrefaction does not occur. The general plan adopted

in such experiments is the same in principle as that we employ when testing a solution: it is only modified to suit the altered conditions.

It is easy to vaporise many substances by heating them in their pure state, and I promised to make a remark upon some of these. For example, benzoic acid, as we all know, is very volatile. If a piece of dry gum benzoin be heated it parts with the benzoic acid. The same thing happens when a piece of gum-benzoin is boiled in water. The benzoic acid evaporates very quickly with the steam. Eucalyptus oil does the same. Here we have two substances which are converted into vapour at very different temperatures. Benzoic acid vaporises below the temperature of boiling water, while oil of eucalyptus must be raised to a much higher temperature; and yet they both vaporise in much the same way when boiled with water. They differ entirely, however, from carbolic acid. The reason is not apparent, but the fact must be clearly recognised if we use any particular substance in clinical practice.

You can easily understand that one person may say that he has obtained such and such results, while another has obtained very different ones, and useless discussion may arise; that is to say, if the methods of vaporising the substance in question are not stated the real explanation of the disagreements is overlooked. It is therefore necessary if we desire to use any volatile substance for clinical purposes to ascertain the proper conditions for its use. I would advise that we should work for some time with carbolic acid alone and test the question of the antiseptic principle as generally as possible. There may, after all, be no value in it. I am inclined to think from personal experience that there is a great deal in it if it is carried out on accurate and scientific principles.

We are too apt at the present day to sacrifice our independence to assumed authority in matters of therapeutics, and I think there is a degree of credulity in our profession which we ought to be on our guard against. We do not trust enough to our own experience, and we are rather too apt to adopt new remedies on insufficient evidence of their merits, and then we are disappointed and discard them. I have been anxious this evening to place before you the question of the antiseptic treatment of a certain class of diseases in such a way as to prepare you to judge independently of the question and to criticise any statements which are submitted to you.

SIX CASES OF SUCCESSFUL REMOVAL OF THE UTERINE APPENDAGES. (a)

By FRANCIS IMLACH, M.D.,

Honorary Surgeon to the Liverpool Hospital for Women.

CASE I.—M. A., æt. 29, entered the Hospital for Women, 7th November, 1883, having been under my care as an out-patient during the preceding four months. Though married eight years, she has had neither child nor miscarriage. For the last seven years she has been almost constantly bed-ridden from pelvic pain and from weakness. Menstrual discharge recurrent every fortnight, and very profuse. Uterus measured four inches, and was slightly mobile; on each side of it a tender doughy mass was detected by bi-manual examination. The temperature varied between 102 and 104 deg. Hot vaginal douches twice daily were given without material relief. On the 29th the left and most prominent mass was aspirated *per vaginam*, and an ounce of grumous pus and blood withdrawn. The next menstrual period being preceded by the customary pyrexia and marked with the usual menorrhagia and dysmenorrhœa, I determined to remove both ovaries and fallopian tubes. An abdominal section was performed on the 7th January, 1884. The left fallopian tube was more than twice as thick as one's forefinger throughout, but

seemed partially collapsed. The left ovary was small and so soft that it broke down when seized. The right ovary, which had undergone cystic degeneration, was the size of a small orange, and closely adherent to the peritoneum deep in the pelvis. The right fallopian tube was thickened in its walls, slightly enlarged, and its fimbriated extremity was adherent to the ovary. When all these structures were removed both tubes were found to be filled with blood and grumous pur. There was some hæmorrhage from the peritoneal surface where adhesions had been separated, but this was soon stopped with sponge compresses. A glass drainage tube was inserted and left for twenty-four hours. The patient made a rapid recovery and left hospital on the 14th February. She was then and is now absolutely cured of her pelvic pain and menorrhagia. She is quite able for household work, and says that she feels as well now as ever she did before marriage and during the first year after it. She is in perfect health, and can walk for miles without fatigue.

CASE II.—M. A. McD., æt. 23, married at 18, two children, the last ten months old. Dysmenorrhœa before marriage, and much aggravated since the birth of the second child. Menstruation lasts eight days, and is profuse. Walking is always painful. On vaginal examination a small cyst was felt on the left side of the uterus, and there was some thickening and great tenderness on the right side. The uterus measured three inches. On the 9th January an abdominal section was made. Both tubes were greatly thickened in their walls, and distended with blood. The right ovary was a cyst about the size of an orange, with fatty contents, in which a few fine hairs were interspersed. The left ovary was three times the ordinary size, and its tube was thickened and adherent. All these parts were removed, and the patient made a rapid and uninterrupted recovery within a fortnight. In all other cases I have used carbolic spray during operation, but this time it was dispensed with, and only pure water was employed for both sponges and instruments. It is possible that the absence of pyrexia or inflammation is to be attributed to the excellent drainage and ventilation of the hospital.

CASE III.—M. Y., æt. 42, married sixteen years, four children and nine miscarriages. Catamenia recur every fortnight, and last eight or nine days. She is a great sufferer from pelvic pain, which is much worse at the menstrual period. The bowels are always constipated, except when aperients are taken, and she is quite unable for household work. Having attended the dispensary for six months without evident relief, and as the frequent railway journeys to and from Southport seemed to increase her pelvic pains, she was admitted to hospital on 19th January. The uterus, which then measured three inches was retroverted and tightly bound to the sacrum. There was great pelvic tenderness, and on the left side of the uterus a small mass was felt, which was thought to be the left ovary swollen and inflamed. On the 24th, abdominal section was performed. The uterus was quickly felt to be adherent to the sacrum, but no broad ligaments could at first be detected. When the tough uterine adhesions had, with great difficulty, been separated, and the uterus raised from the sacrum, both ovaries and fallopian tubes were found tightly packed down behind it, and rather to the left side. These adhesions in Douglas' pouch having been torn through the ovaries were found to be very small and hard, and the fallopian tubes extremely atrophied. As it seemed probable that continued tension had been the cause of the atrophy of the organs, and also of the woman's pain, I was tempted to leave them and to shorten the round ligaments of the uterus at a later date. But fear lest fresh adhesions should take place, and their evident complete loss of function, determined me to remove them. The patient made a satisfactory, though not very rapid, recovery, and left the hospital on the 11th March. Her symptoms have

(a) Read before the Liverpool Medical Institution, May 1, 1884.

greatly improved. She has now little or no pain, and can walk with greater freedom, but is not yet in full health. It is curious to observe that although the ovaries were so atrophied, and there was no appearance of Graafian vesicles in them, menstruation was profuse before the operation, but entirely ceased after their removal. There was, indeed, in her case, as there has been in most of my other cases, a discharge of blood from the uterus within a week after operation, but since then there has been no appearance of the menstrual molimen.

CASE IV.—L. S., æt. 28, married four years, no children, and no miscarriages, was admitted into hospital on 1st February, suffering from menorrhagia. She said she lost bucketfuls, and I had ample evidence both of the profuseness of the discharge, and of the subsequent prostration. When in hospital on a previous occasion I had recognised soft fibroid enlargement of the uterus, which increased four and a half inches in length. Ergot, ergotin injected subcutaneously, and other medicinal agents having already failed, I then dilated the uterus with a sponge tent, scraped the endo-metrium with a wire curette, and applied iodine. No beneficial effect having resulted, the ovaries and fallopian tubes were removed on the 19th February. Although from her fatness, occasional bronchitis, weak heart, and general ill-health, she was an unfavourable subject for operation, she made a rapid recovery, and since then the function of menstruation has ceased. The ovaries were apparently healthy, but the walls of both fallopian tubes were greatly thickened, and their veins were enlarged and swollen with blood. Unfortunately she left hospital against my wish on 16th March, a bleak day with an east wind, and increased her bronchitis.

CASE V.—M. A. L., æt. 21, married three years, no children, had been under treatment at the dispensary for eight months. She stated that she was subject to severe dysmenorrhœa before marriage, and that once for a period of eight months, and twice for a period of four months, she had amenorrhœa. Since marriage the dysmenorrhœa has increased, menstruation occurs every fortnight or three weeks, and lasts nine days. For the past two years walking has greatly increased her pain. The uterus measured three inches, as it generally does in sterile married women, and on each side the tender and swollen fallopian tubes were readily detected. As she was much weakened by her long illness, I removed both ovaries and fallopian tubes on the 13th March. The tubes were distended with ash-grey thin purulent fluid; the ovaries were enlarged, and each one contained two or three small interstitial abscesses. The pain from which she had so long suffered immediately disappeared. Sloughing of a small portion of the sheath of the left rectus muscle somewhat delayed the union of the abdominal incision, but in all other respects her progress has been perfectly satisfactory.

CASE 6.—E. N., æt. 28, married eight years, one child who is three years old, no miscarriages. Having been deserted by her husband she is obliged to support herself and child by work as a shirt-maker, but being unable to continue her employment from constant pelvic pain, "bearing down," and debility, she was anxious for relief, and willingly agreed to the proposed operation. I had already treated her for more than six months at the dispensary, and in November she had been in hospital for a fortnight, during which time the uterus was dilated without relief. The physical signs were slight enlargement and ante-flexion of the uterus, with a painful soft swelling on either side, which can be detected by bimanual examination. She is extremely anæmic, and suffers from dysmenorrhœa and menorrhagia, which recurs every fortnight, and remains eight days. On the 29th of April I removed both ovaries and fallopian tubes. There was about a teacupful of bloody serum in the abdomen, which was carefully sponged out. Both tubes were dropsical; the left tube

containing an ounce of serum tinged with blood, and the right, one-half that quantity. The ovaries were healthy, but somewhat swollen. Probably at each menstrual period the dropsical effusion increased until the tube burst, and the pain was eased by the flow of a portion of its contents into the abdominal cavity.

These six cases are all those in which I have removed both ovaries and fallopian tubes for any purpose whatever. They have all been successful, and the relief of symptoms has been very marked. Lest, however, there should be even the appearance of reservation, I may add that in one case in which I removed a small left cystic ovary, previously diagnosed as such, from a woman, æt. 34, on account of very painful pelvic symptoms, a small portion of the left fallopian tube (which, though healthy in itself, was adherent to the ovary) was removed at the same time, and death from peritonitis ensued. Against this case may, perhaps, be placed that of a patient admitted about the same time with double ovaritis, and an enormous perimetric and parametric abscess, which mounted almost as high as her left ribs, sent up her temperature to 106 degs. and her pulse beyond 150. Had I seen her sooner, I should certainly have advised removal of the inflamed ovaries. As it was, I contented myself with opening the abscess and draining as much of the pus as would run. Though able to walk about, she is now certainly in far worse plight than any of the cases which have been narrated.

Removal of the uterine appendages has been proposed for three classes of cases:—

1. Hæmorrhagic fibroid tumours of the uterus.
2. Inflammatory diseases of the ovaries and tubes.
3. General pathological conditions, as epilepsy, hysteria, &c.

Of my six cases, five have belonged to the second class, and none to the third. How controversy can be maintained as to the suitability of the operation is not easily to be understood. Though the short limit of time at my disposal prevents any consideration of the pathology of the subject, I should like to add that in not one of my cases was there a distinct history of gonorrhœa. I am no follower of the school which ascribes all pelvic inflammation to gonorrhœa and all other diseases to syphilis. The hypothesis I have formed as to some of my cases is, that they have been due to perhaps frequently repeated early tubal abortions.

CONSUMPTION VIEWED IN RELATION TO EVOLUTION AND MOLECULAR ENERGY.

By WILLIAM H. PEARSE, M.D.,

Senior Physician to the Plymouth Public Dispensary.

(Continued from page 514.)

Anatomical.—Many of those whose general ideas do not embrace the hypothesis of "continuity" as absolute throughout other existences, will feel no doubt as to the truth of this great "form" and order throughout the animal structures; their minds will see *a priori* that there must be a region of "comparative disease," and this not only embracing the revelations of helminthology, but also the more subtle and general diseases; but further it will be obvious that a disease such as phthisis will have very wide correlations within the body itself. Further, a just study of the anatomical correlations of those who tend to phthisis may help us to perceive how it is that the formative energy should fail so early and destructively in the lungs—for the body in its embryonic evolution, and in its future structure and function, is but one reciprocal organ or whole.

Large-Browed.—Two cases of adult phthisis seemed continuous with semi-hydrocephalous in early life. In one the frontal region was very broad, the upper maxillary arch small, the two lateral incisors small and pointing obliquely inward. About thirty of the prephthisical were abnormally sunken across the root of

the nose and line of orbits, with flattish brow, perhaps what might have been a degree of hydrocephalus in early life. I have in several instances noted this type in women, who, healthy themselves, have had children die of phthisis.

Upper Maxilla.—In the pre-phthisical and phthisical the upper jaw is often narrow from side to side and markedly out of the mesial line. The nose still more often in those who pass into phthisis has an undue lateral twist. My observations are not enough to establish the exact law of the correlation, but such a correlation is very marked. The twist was to the left in thirty-three cases; of these, twenty-two had the left lung affected; eleven the right. The twist was to the right in forty-seven cases; of these, twenty-two had the right lung affected, and twenty-five the left. In pre-phthisical cases, the nose was toward the right in ninety-six cases, and toward the left in forty-four.

In the phthisical the terminal cartilages of the nose are often unduly large and unsymmetrical on the two sides; the end of the nose may be lumpy, or the *alae nasi* different in shape on the two sides. A common feature is for the end of the nose to be rather pointed on both sides—a kind of double nodulated termination. In one rapid case of phthisis in a young man of twenty-three, who said he was well two months prior, the nose was extremely lateral and had a sulcus at its end. His younger brother, *set.* 18, is now under my care with rapidly developing phthisis, chiefly in the left lung; his nose is much out of the mesial line and towards the right; his eyebrows heavy. On the other hand, in many cases the end of the nose will be extremely fine and pointed and pinched. These structural peculiarities are quite apart from the prevailing stillness of the *alae nasi* and general inexpressiveness of the organ, in the pre- and phthisical.

I have cited these illustrations to show the profound correlation of phthisis to the organic evolution; the deepest forces or laws of the organic and animal innervation are involved.

Under-jaw.—Fundamentally correlated as are the cerebro-spinal segments, most nearly connected in the evolution of the upper maxillary and nasal regions with phthisis, on the other hand, the lower maxillary region shows very little correlation to phthisis. One half-Italian child of seven, who was "underhung," died of phthisis. I have now also under care a seeming pre-phthisical girl of fifteen who has amenorrhœa, weakness, &c., and whose father died of phthisis, who is slightly "underhung;" but I do not remember ever to have seen a person in phthisis who had a prognathic type of face.

I am sure also that there are peculiarities connected with the lips which show future phthisis, *e.g.*, sometimes it may be a wide mouth and full lips; also, often the ears stick out, and are ill-shapen.

The clavicles may be exquisitely fine, but they may also be unduly large; and, further, the bone system in general may be very small and exquisite in form; or the bones may be large in the clavicles, tarsus, carpus, &c., &c., showing disturbed or irregular innervation, evolution or development. The set-up of the neck is often poor, looking as though it had sunken down somewhat into the top of the thorax.

The thorax in the phthisical may be well developed, both generally and in the infra-clavicular regions; but where it is extremely small, we must not look at such a state as resulting from want of exercise, but in the main, as fundamentally due to defective nerve "energy" in certain segments of the cerebro-spinal axis.

Whilst a large number of phthisical cases have elegant hands, yet there is a considerable proportion whose hands are unduly large. I have often rightly predicated phthisis from a glance at the large cold hand of the patient; the unduly small hand is not so common.

I have grouped the foregoing anatomical correlations of phthisis as belonging to the nerve and bone segments;

they indicate disturbed innervation in growth or evolution, and show how far back we have to look for the roots of phthisis, and remind us that although conventionally, phthisis is a "disease," yet philosophically, phthisis is in absolute natural "continuity." It seems to me of very great importance to our method that we deeply study these correlations of the so-far fundamental nerve and osseous segments to phthisis; our views of the disease will thus deepen and widen, and our methods of prevention will thus pursue earlier and more controllable deviations.

The skin system shows not less striking correlations to phthisis. We must, however, carefully remember that the skin system is not isolated, but is absolutely in relation to the whole body and nerve centres. We shall never grasp the true "form" of any disease, unless we carefully guard our minds against the existing influence of words and definitions; but we may fairly, but approximatively, use the term "skin system" in referring to the correlations of the skin, hair, teeth, nails, &c., to phthisis.

I remember that the late Professor Alison used to teach that he had often recognised a relation between great delicacy in the texture of the skin and phthisis. I often see such in the pre- and phthisical; not only is the surface unusually smooth and fine, but the skin seems thinner than normal. In a few cases of phthisis, a discolouration of the skin has come on, as in pregnancy. I have seen phthisis in those who have a great abundance of freckles. One woman of 40, with advanced phthisis of the left lung, had for six to eight months a small strumous wound on the brow. It has healed, her phthisis has not advanced, her general condition is better than it was a year ago; she has taken quinine, arsenic, and muriatic acid. I watched the slow healing of the little wound with great interest; if vital energy and growth would be restored there, how, not in the lungs? The deep involvements and correlations of the skin system are well illustrated by the following case:—Mrs. K., *set.* 36, an unusually fine woman, has had lupus of the right cheek and end of nose during the past three years; she was in perfect health before then, "hadn't a blemish." She says that her disease commenced from a scratch which she received from a child. She is the youngest of eleven children; all her brothers and sisters are healthy; her five married sisters all have families; she had been married nine years, had regular menses, but has never been pregnant. Her father was sixty, and mother forty-five, when she was born, her mother having stopped having children for four years prior to her birth. Her disease has arrested in progress, and the surface healed under the use of arsenic, quinine, muriatic acid, lemons, &c. The deeper points of her case are the age of her parents, the seemingly previous expiry of her mother's fecundity, the patient's barrenness, the natural devolution of healthy growth at 35, in the parts most remote from central nerve force, the restoration of vital "energy" and growth, by certain minerals and organic compounds of unknown molecular powers. Such cases help us in a right method of viewing the great breadth of phthisis. Conventionally her lupus was a disease; philosophically, it was a natural devolution, having absolute correlation in the general and nerve systems, and with roots in the embryonic evolution of the patient. We know empirically that the contained, latent, "modes" of arsenic, quinine, and muriatic acid, became correlated vital "energy." No doubt exists that with the progress of science and method, the deviation and devolution of the skin of such cases as this woman, and the restoration of the "energy" by certain forms of matter, will be reduced to exact statement; we hold it as an *a priori* "necessary truth," that "nothing is created, nothing lost;" the whole process in this woman, from her conception to her approximative cure, has been within the reign of exact law, and of the "correlation of energy."

Hair.—The fact of a correlation between the hair and phthisis is being constantly forced on my observation. 113 of the pre-phthisical and phthisical had heavy eye-brows, which tended to meet in the middle line. In our present infancy in knowledge of the "form" of the complex organic series, we may well fail to know the steps and process of this "continuity;" but it has a most striking correlation to phthisis. I often see cases of phthisis, where these heavy and meeting eye-brows are associated with the excessive lateral position of the nose; in another class of cases, the eye-brows may be exquisitely pencilled and delicate in shape. The hair of the scalp is often enormous in amount in those who tend to phthisis. In men the whisker is sometimes tufty and scant. The hair in phthisical girls is often wavy. I have cases noted in which enormous scalp hair, small lateral incisors, and phthisis co-existed. One fine man, *æt.* 35, with phthisis of the left lung, had the hair on his breast scant, but developed in spiral-like curves. In a child of seven, who died of phthisis, a very scant whisker developed. Our knowledge of the laws of embryonic evolution, and of their "continuity" with molecular energy does, not yet show us how it is that such organic types are apt to show the cell devolution of tubercle, at the varying ages at which young adults pass into phthisis.

Atavic phenomena.—I have a beautiful young woman of 26 now in advanced phthisis, her upper incisors are small, regular, and not decayed; her elder sister, *æt.* 31, has enormous hair, regular, but decayed lateral incisors, her nose is lateral and unsymmetrical; married to two husbands in ten years, she is yet barren, their mother died of phthisis. Another young woman, *æt.* 23, with phthisis of the left lung, has an elder sister lame from old strumous disease of the ankle, whose middle upper incisors are large, the lateral incisors very small, the left lateral incisor being extremely small and conical.

(To be continued.)

Clinical Records.

ST. BARTHOLOMEW'S HOSPITAL.

Case of *Pyæmia*.

Under the care of Dr. REGINALD SOUTHEY.

[For the report of this case we are indebted to Mr. ALBERT GRESSWELL, B.A. Oxon., M.R.C.S.]

RACHEL C., *æt.* 15, was admitted to Faith Ward, on September 6th, 1882; died on September 14th. She was a well-nourished girl, of fair complexion, and had recently been engaged in housework of various kinds. The catamenia had not yet commenced. On admission her mind was quite clear, she shivered frequently, and her hands were somewhat tremulous. She lay fixedly on her right side, complaining of great tenderness over the left hip.

The skin was dry and hot, and presented no rash. There was marked sallowness of the skin of the abdomen. The tongue presented a dry brown centre, which was slightly fissured transversely, and its sides were coated with a moist yellow fur. The lips were covered with sordes. The pupils were equal, and reacted freely to light.

The chest presented no abnormal signs; the movements, the resonance, and the breathing sounds were normal. The heart's impulse was somewhat feeble, and the first sound at the apex was prolonged.

The abdomen was of natural fulness being neither distended nor retracted. The area of the splenic dulness was slightly increased.

There was great tenderness over the left hip; otherwise the extremities presented nothing unusual. The temperature on admission was 102°; the pulse 108, soft, full; the respirations 36. The urine was acid, of sp. g. 1026, and contained no albumen. The patient said that she had always enjoyed good health until two weeks ago, when the present illness set in, with gradually increasing loss of appetite, headache, and chilliness.

Four days before admission the bowels had been loosely open four times, but have only been once open daily since. She vomited on the evening before admission, and has ever since felt very sick. She said that great tenderness of the left hip had prevented her from lying on the left side, and that she had a little cough, and had raised much darkly coloured phlegm.

Ordered D.L., beef-tea and arrowroot. *Haustus ammoniac acetatis c. camphor*, ʒj.; and *spiritus ætheris nitrosi*, ℥xxx.; *quartis horis*. The following notes record her condition from day to day:—

September 7th.—Passed a good night. Has taken food well. Bowels have not been open. Passed water freely. Lies comfortably on either side. Tongue very dry. Skin has no rash. Pulse 120, soft. Temperature last night, 102°6; this morning 102°4.

8th.—Complains of pain in the back and in the hips. Bowels have not been open. Pulse 120, softer. Respirations 30. Temperature last night 103°; this morning 103°6. Diet changed to D.L., milk, barley water. Ordered a tepid bath at 96° Fahr. for 15 minutes. Bath to be repeated if the temperature should reach 102°5°.

9th.—Passed a fairly good night. Bowels not open, but has passed an *ascaris per anum*. Numberless slightly raised vesicles appeared on the skin of abdomen, chest, and back during the night. Pulse 96, still softer. Respirations 28. Temperature last night 103°4, was reduced by bath to 100°, but rose in an hour to 102°. This morning temperature is 101°8°. Ordered *ol. ricini*, ʒij.; and tepid bath (if temperature should reach 102°5° Fahr.).

10th.—Has passed a good night. Bowels open ten times during the last 24 hours, the motions being loose and light in colour. The skin all over the right hand is very red. The vesicles are larger. The temperature last night was 101°8° this morning 100°8°. Ordered *enema amyli c. opio* (tinct. opii, ℥ xx.).

11th.—Has passed a fair night without delirium. Bowels not open since administration of the enema. Is very thirsty, the vesicles are pustular and perhaps slightly larger. Pulse 120, and much more compressible. Respirations 42. Temperature last night 101°8°, this morning 101°. Has complained ever since admission of a dull aching pain in both hips, the legs, and shoulders.

11th (continued).—A large tender swelling of the left cheek, which is very painful, developed in the region of the left parotid gland, very suddenly this morning shortly after she was washed. The swollen cheek is hot but not red. Two very painful red elevations also now present themselves on the dorsum of the little finger. On the base of each lung behind laterally, and in front are heard crepitations and friction sounds. Ordered D.L., milk, brandy, ʒiv.; eggs, iv.; *cataplasma lini* to left cheek, *infusi cinchona*, Oj.; *acidi nitrici diluti*, ʒj.; *tinct. cassia*, ʒj.; *syrupi durantii*, ʒj. (as a drink during the day).

12th.—Has been very restless the last 16 hours and was a little delirious in the night. Bowels not open but passed another *ascaris per anum*. Pulse 120, very soft. Respirations 48. Urine passed freely, sp.g. 1024, neutral; no albumen. Abdomen not tender, presents no spots. Area of splenic dulness enlarged. The pustules slightly shrivelling. No tenderness along the saphenous veins. The painful swelling of the little finger of the right hand has disappeared. The redness of the left forefinger is of deeper hue, but the swelling, though not larger, is more irregular, and presents an appearance as if the skin was the seat of one, or more patches of *erythema nodosum*. Temperature last night 101°, this morning 101°. Shivered yesterday about noon, and the temperature rose to 103°. Ordered brandy ʒv.; *essence oss.*; *lotio plumbi c. opii* to be applied to the fingers.

13th.—Was somewhat delirious in the night, and had very little sleep. Has taken food freely. Is now perspiring profusely. Tongue very dry and brown. Swelling of the left cheek rather smaller, hard and not fluctuating. Area of splenic dulness not increased. Right pupil much larger than the left, both however reacting freely. Urine is acid, sp.g. 1016, contains a trace of albumen. Water passed under her during the night. Bowels open twice last evening. Pulse 130, very soft, small and weak. Respirations 60. Temperature last night 101°8, this morning 101°. Ordered brandy ʒvj.

14th.—Delirious throughout the night. Pulse last night 150, extremely weak and small. Respirations 75. Very sick

this morning. Very thirsty, drinking freely. Bowels open once this morning. Has passed water freely. Pulse 156. Respirations 68. She continued insensible through the day, perspiring freely. She gradually sank and died.

A post-mortem examination was made by Dr. Astley Gresswell.

The heart was found to be very flabby. The parietal and visceral layers of the pleurae were injected and covered here and there with white coagulated lymph. The visceral pleura over the base of each lung presented pustular points which, on section, were found to be minute abscesses in the superficial parts of the lungs, and surrounded by areas of vascular engorgement. There was much hypostatic congestion of the base of each lung. A small subperiosteal accumulation of pus was found under the left iliacus muscle, as well as a very small amount (about 3j.) of watery pus in the left hip-joint. The left parotid gland was greatly enlarged and infiltrated with small purulent masses, and there was a small collection of pus between the fifth and sixth cervical spinous processes. The rest of the body presented nothing unusual.

Remarks.—The symptoms at first simulated those of enteric fever, for at the time of admission the illness had already lasted a fortnight. The onset was very gradual, and was ushered in with headache, chilliness, and gradual loss of appetite. The area of splenic dulness was increased, and there had been some diarrhoea. On the other hand, there was no tracheal catarrh, so common in enteric fever, there were no rose-coloured spots, the abdomen was not distended, and the diarrhoea did not continue more than one day. Shortly after admission, however, the symptoms of pyæmia manifested themselves. The vesicles on Sept. 9th, which later became pustular, the sudden swelling of the left parotid gland on the 11th of September, the crepitations and friction sounds over the bases of the lungs, and the swellings on the fingers all spoke of pyæmia. The post-mortem fully bore out the diagnosis, and revealed to us the probable sequence of events. The pus formations in the skin, in the parotid gland, the lungs, and elsewhere, were probably the result of inflammation, set about by the septic matter absorbed from the inflammatory centres under the periosteum of the centre of the left iliac bone, or in the left hip-joint. This case is the more interesting if we compare with it a case of a lad admitted to Mark Ward, and then transferred to Radcliffe some few months previously. This patient complained of chilliness, of great thirst, and of a very dry and parched mouth. He died about two days after admission, and at the autopsy an accumulation of pus was found in the right hip-joint. Pericarditis and other probably secondary lesions were also observed. A somewhat similar case, moreover, was treated by Dr. Church, and in it also pus was found in the left hip-joint.

THIRD GERMAN CONGRESS FOR "MEDICINE."

THIS gathering, as already announced, followed closely the meeting of the Society for Surgery, and was held in Berlin from the 21st to 24th of April, under the presidency of Frerichs.

DISCUSSION ON PNEUMONIA.

An important discussion on pneumonia took place on the 21st, and as might be expected from the place of meeting and from the names of the principal speakers the talk was a good deal of the pneumonia micrococcus and the part attributed to it in the causation of the disease. The subject was introduced by two papers by Jürgensen (Tübingen) and A. Fraenkel (Berlin). The former gave a brief historical sketch of the views that had been prevalent at various times regarding the nature of the disease, and then proceeded to give those held by himself. "Croupous pneumonia," he said, "was a general disease, the inflammation of the lung only its principal symptom. The phenomena of the disease could not be explained by the local affection, the adoption of a specific disease originator was necessary. Croupous pneumonia belonged to the group of infective diseases." Ten years ago he was compelled to bring his proofs of this from a tolerable distance, but to-day experimental pathology furnished immediate proof. He would start out from the proposition which he held to be proved: pneumonia was an

infective disease, and we knew the originator of it. Statistics gave "cold" as the cause of the disease in from 2 to 20 per cent. of the cases. During the last 10 years he had determined in every case coming before him, not only that "cold" was the cause, but in what the cold consisted. The percentages were 10·2 per cent. gross and 4·1 nett. If one were really to take cold into account one could easily represent the catarrh as rendering the admission of the micro-organism more easy, and as furnishing for it a more favourable soil to grow in. A second important point was that the disease was not preponderantly prevalent during the years of greatest vigour. The erroneous view that it was, had its origin in the fact that hospital material was almost exclusively the only kind made use of. If you took the whole population, the years from 1—14 furnished nearly three-fifths of the cases, and the later years from 45 upwards double as many as the years between 20 and 44. Dittell had already noted that those who were suffering from temporary debility were attacked more readily than the strong, he gave 18 per cent. of the cases as occurring in those previously quite healthy, whilst Flint, of Denmark, gave the proportion as 21 per cent., he, the speaker, had found it to be 29·3 per cent. To the question whether pneumonia had any dependence on meteorological conditions he must answer, yes. From observations carried out for a period of 10 years it was shown that in Tübingen the disease exhibited a certain relationship to the amount of atmospheric downfall, that when this was above the average the effect was a disturbing one, and that when it was below, the occurrence of pneumonia was favoured. Keller had gone further than this and had formulated the proposition that relative moisture of the soil hindered, and dryness favoured, pneumonia. Out of a ten years' observation the further fact was adduced that pneumonia was a "dwelling" disease as typhoid was. It clung to the locality. The speaker reached the conviction from observing an epidemic of pneumonia in Amberg that the sleeping-room was the breeding place of the disease. Three or four years later the pneumonia cocci were found under the flooring of the rooms, cultivated and transplanted to animals, and thus furnished the proof that his conviction was sound. Further observations on the pathogenesis of the disease were necessary, however, and even if the relationship between the disease and the micro-organism were proved to be constant only one more factor would have been obtained; the regular distribution over the whole year and the occurrence of local epidemics still remained unexplained. It was observed spreading through garrisons, prisons, and villages, and then again limited to certain houses. It was possible that epidemics did not become general from the pertinacity with which the disease clung to localities, and perhaps also considerable individual predisposition must also be present before an outbreak of pneumonia could take place. The possibility of the immediate transference of the poison from one person to another could not be denied, but such instances were extremely rare. Flint during six years observation had marked a direct or indirect connection with earlier cases of the disease in nearly two-thirds of the cases. It would be rather hazardous to say that pneumonia was an infectious disease. The question of the unity or otherwise of the pneumonia poison could soon be decided by the inoculation of the isolated and cultivated fungus upon other individuals. He was of opinion that the poison circulating in the blood could find a place for development anywhere, and that no organ was safe from it, as those cases showed in which the brain and its membranes, the kidneys, the alimentary canal, and especially the heart had served as places for its development. Croupous nephritis was not rare. Nauwerck found Friedländer's cocci in the kidneys of thirteen individuals who suffered simultaneously from nephritis and pneumonia. He had seen the cocci develop in the vessels of the kidney, and especially in the colonies of veins. This could only be taken to mean that germs introduced into the system developed and formed new centres. In one of his cases he took it that the poison was present in the kidneys before it was in the lungs. He himself observed an encephalo-meningitis in the course of a pneumonia, moreover, discharges of blood into the intestinal tract were very frequent in genuine pneumonia, which he looked upon not as congestive hemorrhages but as localisations of the poison. The temperature curve also was slightly irregular as was the case in malaria and recurrent fever and from the same cause—origination and disappearance of the exciting cause.

The newly discovered facts had really added much from a therapeutical point of view. The hygiene of dwellings had become of eminent importance from the proof of the cocci beneath the flooring. Regarding the use of iodine as an abortive his results had been of a negative character. He held firmly to immediate lowering of temperature—extraction of heat, and pleaded for prophylactic treatment, and above all for timely sparing of the heart whereby speedy convalescence was brought about. That the heart could be temporarily relieved by blood-letting was plain, but it was doubtful if this procedure was often of value. In conclusion he advanced the following propositions:—Genuine pneumonia was an infective disease which was preponderantly, but not exclusively, localised in the lungs. Cold was more rarely a cause of the affection. The vigorous were less frequently attacked than the weak. Antiphlogistic treatment, as understood by our forefathers, was to be rejected.

Herr A. Fraenkel (Berlin) would deal more with the originators of the disease, and not only discuss what was already known but also supplement somewhat on the basis of his own investigations. After referring to the results of Friedländer's labours, the so-called nail cultivation on meat gelatine, and the mucin envelope surrounding single cocci, diplococci, or groups of them, to the remarkable fact that the capsule was not present under all circumstances, but that it was altogether absent in many pneumonic exudations, and in other cases, partially so, he said that Friedländer was inclined to attribute these differences to age and stage of the inflammation. Rabbits, according to the same authority, had shown themselves completely refractory in inoculative experiments, whilst mice succumbed with extraordinary rapidity with double pleuritis and inflammatory centres in the lungs. Guinea pigs were a mean between the two. Out of five dogs a typical lobular pneumonia was produced in one by injection. Respecting his own investigations, early in 1883 he had succeeded in cultivating the microbes of pneumonia. If a small quantity of this cultivated material was injected into rabbits the animals died without exception with extraordinary rapidity. This result differed markedly from Friedländer's. On examination the lungs were either found intact or moderate effusion was present in both pleural cavities. Other rabbits could be infected either with the blood of the dead animals, or with the cultivated microbes, except that the pleural exudation was more frequently absent. Guinea pigs differed so far from rabbits that a number were quite refractory, and others died in the course of a few days, and showed pleural and peritoneal effusions. He then took some exudations from two other cases of pneumonia, cultivated, and then made comparisons by inoculating with the cultivated virus and with fresh exudation scraped from a section of pneumonic lung. From a comparison of the whole of these observations it appeared that rabbits were acted upon according to the nature of the material of inoculation. In the first case they died, as stated, without exception; in the second, they were refractory without exception; and in the third, a fever was set up that lasted several days. In inoculation with exudation from lungs, the animals sometimes died speedily, and sometimes recovered. There could be no question of impurities in the case of the first series of inoculations. He believed that rabbits were susceptible to the pneumonic coccus under certain conditions. Friedländer had already noted that the capsule formation was not present under all circumstances; he could supplement this observation by the fact that in addition to the pneumonic micrococcus there was still another which showed the capsule in a marked manner, one which was present in the oral cavity of every individual. He designated this as the micrococcus of sputum septicæmia. These could be easily isolated by inoculating rabbits with mucus from the oral cavity. Many died in 24 or 28 hours, and at the point of inoculation only a slight inflammatory re-action was to be seen, whilst in the blood masses of the microbe were found, and these were again transferable to other animals. Only two points of real distinction were observable between the two corpuscles; that of the septicæmic micrococcus appeared after uncolouring by alcohol as a broad, colourless covering, whilst in that of the pneumonic coccus the colour was rather more firmly fixed. The second point of difference was in regard to form. He advanced in conclusion the following propositions: 1. The coccus of pneumonia which could be cultivated purely was transferable to various species of animals. It appeared that according to the case from which the exudation for cultivation was taken rabbits were either refractory or they died

with symptoms of severe general disease, or with special localisation of the virus upon internal organs, the pleura or pericardium. 2. It must remain for further investigations to decide upon what the varying behaviour of the rabbit depended. 3. The development of a capsule as well as the peculiar nail-like form of the pneumonia cultivation was not constant. 4. In regard to the so-called capsule, this was present also in the case of other fungi, and in a striking manner in the microbe of sputum septicæmia. 5. Nail cultivation could only be looked upon as the expression of energy and growth, and as an appearance that in all probability could be assumed by other fungi. 6. For these reasons it was not possible from the presence of the two last named phenomena to characterise the pneumonic micrococcus as such.

Herr Friedländer (Berlin) remarked that he had been able, in a series of cases of acute pneumonia, to examine blood removed by cupping. The skin, knives, and vessels were all sterilised so that the blood was perfectly free from impurities. The blood was employed for inoculations, and parts of it kept in gelatine at the heat of the body and of the room. In five out of six cases of pneumonia the blood remained perfectly sterile, the sixth case gave a positive result; out of twelve points of inoculation one developed a growth of micro-organisms. Its appearance, as well as the results of experiments on animals, reminded one of the "nail" culture of pneumonia. The rabbits remained healthy, the mice died in a manner completely typical of pneumonia and pleurisy. In these animals the capsules could be demonstrated; the pathological product employed in inoculation again gave the "nail" culture, so that it was demonstrated that in certain cases or stages of pneumonia the coccus of pneumonia was present in the blood in a living form. That the coccus was absent in a great number of cases was no wonder. The capsule or the growth in the nail form were valuable criteria under certain circumstances, but one should avoid giving a scientific diagnosis based only on one of these appearances. What he considered as characteristic for the pneumonic coccus was the complete circle of manifestations,—the capsule, the "nail" culture when transferred to gelatine prepared in a certain way, the behaviour of these cultivated organisms when transferred to animals, and finally the effect upon the animals themselves. Either there were various kinds of pneumonia, and only one of them was referrible to the pneumonic coccus, or these were no longer present at the moment of examination, or they were no longer visible, and were changed. He was inclined to accept the first view. The main point to strive for was to ascertain the conditions under which the coccus ceased to grow and died. These conditions were present in the system; out of it its life was almost indefinite, whilst within it had to struggle with other conditions, to which it succumbed in the majority of cases.

Herr Gerhardt (Würzburg) held with Jürgensen and completely accepted the unity of the virus. He also considered it a happy thought to include the complications, such as meningitis, nephritis, &c., as resulting from the action of the virus upon the various organs. The expectant treatment was at present the one justifiable.

Herr Fräntzel (Berlin) was opposed to the view of Jürgensen that pneumonia was a disease of living rooms. Whilst serving in the military hospitals he made the observation that frequently many people at a time when they were exposed to the weather sickened of pneumonia and the disease spread through the whole barracks, whether the rooms were high or low. He believed the micro-coccus entered through the air passages. Those cases in which bronchial catarrh preceded the pneumonia created the impression that in these the germs more easily found a nidus.

Herr Rhüle (Bonn) thought we were in a transition stage in regard to our view of the disease. If it could be proved that the coccus was present in all cases of pneumonia, it would not prove that it was the cause of the disease. All the facts that had hitherto been collected, were but the commencement of unavoidable inquiry, and were not data upon which to found a doctrine.

Herr Nothnagel (Vienna) spoke principally upon treatment and saw no need of alcohol as was the case in typhoid.

Herr Rosenstein (Leyden) said pneumonia might be an infective disease, but was not necessarily so. He referred to the case of a person suffering from contracted kidney, and then dying of croupous pneumonia. It could not be argued that in such a case the poison was the same in both the kidney and the lung. He would say that pneumonia

could be an infective disease, was so in many cases, but apparently not in all. He was opposed to the view of the unity of the virus.

Herr Bäumler (Freiburg) seemed to be in doubt as to what to believe.

Herr Edlessen (Kiel) found from a comparison of the cases of pneumonia in the Kiel polyclinic, a striking confirmation of the statement of Jürgensen, that a definite relation existed between the number of cases and the meteorological conditions (downfall).

Herr Jürgensen in reply said the differences of view had their origin in the difference of material. Secondary pneumonia was not in his opinion a croupous pneumonia.

Herr Fraenkel was rejoiced that Freidländer essentially agreed with him. The question of the unity of the poison could not yet be finally solved. The spread of the virus must first of all be studied. The pneumonia coccus was undoubtedly present in all cases of pneumonia, but its virulence was apparently exceedingly varied in degree.

Transactions of Societies.

LIVERPOOL MEDICAL INSTITUTION.

THE Fourteenth Ordinary Meeting of the Session was held on Thursday, May 1st, 1884, Dr. GEE, President, in the Chair.

Dr. BARR exhibited a

MEMBRANOUS CAST OF THE TRACHEA AND BRONCHI DOWN TO THE FIFTH DIVISION, FROM A CASE OF DIPHTHERIA.

The history of the case may be briefly stated as follows:—M. J. A. B. J., æt. 6 years and 8 mon this, was first seen by Dr. Barr on April 7th, when he found her suffering from well-marked diphtheritic patches on both tonsils. Her condition rather improved, and the patches almost disappeared from her throat, but, on the 11th the disease attacked the larynx. The dyspnoea did not become urgent until the morning of the 15th, when Dr. Barr assisted by Dr. Archer, performed tracheotomy. When the tube was placed in the trachea the air rushed in with a loud hissing sound, but immediately afterwards there were signs of suffocation and the child was in imminent danger, which, however, was quickly relieved by the child coughing up a complete tough membranous cast of the trachea and bronchi. The dyspnoea then subsided and the child was very comfortable, but the following day she sank from exhaustion about 27 hours after the operation. This was a beautiful, complete, tough membranous cast of the trachea and bronchi down to the fifth division. It also exhibited markings from the rings of the trachea and the primary bronchi.

Dr. BARR exhibited a

HEART SHOWING WELL-MARKED AORTIC-STENOSIS,

taken from a patient who had been under his care in the Stanley Hospital. The heart weighed 28 ozs. The aortic valves were very much thickened and calcareous and so united at their edges that the opening would not admit more than the tip of the little finger. The commencement of the aorta was very atheromatous. The left auricle was greatly hypertrophied, but the muscular structure was healthy. The mitral valves were much thickened and slightly hypertrophied, and the tricuspid orifice was much dilated.

Dr. HYL A GREVES showed

SPECIMENS OF GREAT ENLARGEMENT OF THE CERVICAL, MEDIASTINAL, AND MESENTERIC GLANDS OF A TUBERCULOUS NATURE,

taken from a boy, æt. 10, with the following history:—Was quite healthy till about eighteen months before, when the glands in the neck began to enlarge, since then they had gradually increased in size, and during this time he had been gradually losing flesh and strength. When admitted into the Infirmary for Children, on Dec. 7th, 1883, he was greatly emaciated and very pale, the great size of the cervical glands produced great disfigurement. The axillary and inguinal glands were also slightly increased in size. The abdomen was distended and tense, and contained a little fluid, and tender on pressure in the right lumbar and hypogastric regions. There was only 42° of hæmoglobin

and a great increase in the number of white blood corpuscles, which were large and extremely active, there was one white to forty-five red corpuscles. On Feb. 21st, 1884, he began to complain of headache and lost his appetite, he became worse and gradually weaker. On March 21st he was delirious at night and uttered the peculiar sharp "hydrocephalic cry," but said his headache had gone, he was quite sensible in the day when spoken to, and although continually crying out, when questioned about it, he said he did not know that he was doing so. His temperature had been constantly about 100° F. for some weeks. The head became a little retracted, and his pupils dilated and sluggish, he continued to cry out and died, without any other cerebral symptoms appearing, on March 2nd. Post mortem.—In addition to the general enlargement of the lymphatic glands, there was well-marked tubercular meningitis, especially on the upper surface of the cerebellum, but very little in the usual situations, this might explain the absence of many of the characteristic symptoms of tubercular meningitis. There was a considerable amount of fluid in the ventricles with softening of the brain substance around, and flattening of the convolutions. The lungs were full of miliary tubercles, and there was general tubercular peritonitis. The chief points of interest in the case being, 1. The long duration of the lymphatic enlargement before any cerebral symptoms appeared. 2. The large increase in the number of white blood corpuscles. 3. The presence of well-marked tubercular meningitis without the usual symptoms, the only ones present being the hydrocephalic, with slight retraction of the head, and dilated pupils.

Dr. IMLACH showed as card specimens a strumous kidney, and an ante-flexed uterus and atrophied ovaries from a woman, æt. 26, who had been the subject of absolute amenorrhœa.

Dr. J. CAMERON related a case of

BRONCHOCELE TREATED BY HYDROFLUORIC ACID.

The patient was a female, æt. 20, a native of South Wales, who up to the commencement of the affection had enjoyed good health in every respect and whose health remained good throughout, independently of the bronchocele. The enlargement began in 1881, and in the autumn of that year was the size of a large orange. The whole gland was affected, but the right lobe more than the left. It was soft and painless, and the breathing was stridulous. It had already been treated by the routine methods but without much benefit. Hydrofluoric acid was now given and continued for three months, but without perceptible improvement. Some time after its discontinuance, however, it grew more rapidly, and caused greater dyspnoea and stridor. Dr. Cameron thought the accelerated growth was due to the withdrawal of the hydrofluoric acid, and began the treatment again, after which, the tumour first ceased to grow, then became smaller and now only a trace of the right lobe remains. The dose ordered by him was, at first, 15 minims, afterwards 45 minims twice daily. Generally, however, only one daily dose was taken. The treatment was continued for two years. The large dose produced nausea, which was prevented, however, by taking it after a full meal. It caused loss of flesh, but the general health continued good. He was inclined to think that, as many other drugs had been used without effect, the hydrofluoric acid was of benefit.

Dr. CARTER would suggest that the method of sending out the drug might have had something to do with the long treatment required, as if sent out in glass bottles all but the first few doses would be practically useless.

Dr. C. G. LEE suggested from the analogy between the diseases that hydrofluoric acid might also be found useful in post pharyngeal disease also described by Woakes, and in Addison's disease.

Dr. W. WILLIAMS had seen Dr. Cameron's case and was able to corroborate all that he had said concerning it.

Dr. LOGAN suggested that the drug acted as fluoride of silicon.

Dr. CAMERON in reply, said that the drug could be given in larger doses and more frequently. Another case was under treatment at the present time and had improved since December.

Mr. DAMER HARRISON reported three cases of wiring of bone and showed the patients, after which

Dr. IMLACH read a report of

CASES OF REMOVAL OF THE UTERINE APPENDAGES, which will be found on page 533.

Dr. WALLACE had operated in these cases many more times than Dr. Imlach, and he considered that he was in a position to speak to the value of the operations. In hydro- and pyosalpinx as in uterine fibromata, operations had frequently been performed that had better been left undone. He spoke of the operation unsexing women and deprecated it on this account. He had been begged by a patient not to unsex her, and had removed one ovary and retained the other after puncturing several small cysts. Some of these cases got well, the fluid finding its way into the uterus and peritoneum. He had drained a case through the fallopian tube and the cyst had not refilled. There was a doubt as to the diagnosis being correct.

Dr. BURTON thought the Society was indebted to Dr. Imlach for bringing his cases forward. The operation had done good by drawing the attention of the profession to a class of diseases previously overlooked. He was certain there were cases that required operative treatment. The diagnosis could not, however, be made at once. He had seen cases in which a tumour or swelling was well-marked and continued so for weeks, but on later examination nothing could be found. Medical and general treatment would often remove symptoms, and he mentioned a case in which blisters, saline purgative, and a strengthening treatment had removed all distressing symptoms. Such patients were generally neuroathenic, and this condition required attention. He pointed out that in ovarian diseases the termination, if not interfered with surgically, was almost always fatal, and operation was undertaken to save life, but in the diseases under discussion the termination was rarely if ever fatal; after a time the parts accommodated themselves to their new conditions, adhesion became less tense and pain subsided at the menopause. Bearing in mind the non-fatal character of the disease, the mortality from operation (6 per cent.) was much too high to justify it, except in extreme cases. Even if it were reduced to 2 per cent. it would still perhaps be unjustifiable. Gusserow, of Berlin, had recently had a series of nine operations, and in three of them he had removed nothing, and these patients were as completely cured as the others. This was very suggestive, and might lead to a modified form of operation. Dr. Wallace's objection that the operation unsexed the patient, the speaker did not think of much value, for the disease itself rendered the patient unfit for wifely duties, and unsexed her as much as the operation. Indeed, patients were rendered more fit for cohabitation by the operation.

Dr. ALEXANDER agreed with previous speakers as to there being a legitimate field for the operation, but thought it should be as much restricted as possible. He mentioned a case in which, three months after operation, the symptoms returned. He thought some cases were operated on that should not be. He alluded to a case which was admitted into a hospital in which a good many operations of the same kind were performed. The case was diagnosed as one suitable for operation, and operation was proposed accordingly. The patient, however, was reluctant to undergo so grave an operation and went to Wales where she consulted a medical man. This one diagnosed some bowel mischief and treated her, when she recovered, and she was now a most useful and active nurse in his (the speaker's) own wards. In some other cases he had operated with perfect relief of all symptoms.

Mr. PAUL had over and over again seen cases, post-mortem, in which the fallopian tubes were adherent, and as sure as this was the case they were dilated and full of fluid, but in every instance the tubes were open to the uterus.

Dr. IMLACH, in reply, said he had seen a fallopian tube dilated to the size of his wrist and filled with pus and blood in which the uterine opening of the tube would easily have admitted number 10 sound. Notwithstanding this patency the tube had remained distended. Dr. Wallace claimed that he had a much larger experience of the operation than Dr. Imlach had. Yet he protested against its propriety, and said he always cured his patients by tapping *per vaginam*. He did not know where Dr. Wallace had gained this large experience. He chanced to hold in his hands all the annual reports of the Royal Infirmary since Dr. Wallace's appointment. Only in the last report was there any note of such

operation. In the course of last year Dr. Wallace performed abdominal section for disease of the fallopian tubes four times, but in former years not once. Furthermore these four cases are set down as exploratory incisions, and only two as having recovered. It was not evident, therefore, whether Wallace had ever performed the complete operation. As regards his alleged constant success by tapping *per vaginam* the same reports showed that he had only tapped one, and the woman unfortunately died.

[Dr. Imlach has requested us to add that, in an overlooked second case of tapping by Dr. Wallace for pyo-salpinx, the patient did not, indeed die, but she is not recorded as having recovered. She "remains under treatment"]

ODONTOLOGICAL SOCIETY OF GREAT BRITAIN. MONDAY, MAY 5TH.

Mr. J. S. TURNER, M.R.C.S., L.D.S., Esq., President,
in the chair.

MR. STORER BENNETT showed, for Mr. Balkwill, of Plymouth, the skull of an English black rat, which illustrated in a very remarkable manner the serious results which might happen to rodent animals from the continuous growth of their characteristic teeth when from any cause their normal antagonism was lost. In this case the two lower incisors had been deflected to the left, and the two upper to the right, so that they did not meet in the usual way. The right upper tooth had described one complete circle and three-fourths of another, but being well inclined outwards it had not met with any obstacle. The right lower tooth had penetrated the upper jaw and the parts above, and its tip projected a quarter of an inch above the highest point of the skull. The left upper tooth, after describing a complete circle, had encountered the front of the upper jaw, which it had penetrated to the depth of one-third of an inch. The left lower tooth had been broken off. The lower jaw was thus quite fixed, and the animal could only have obtained nourishment by means of suction.

Mr. E. G. BETTS stated that he had found ethylate of sodium very useful for obtunding the pain of sensitive dentine. Before applying it the dentine should be carefully dried, and the application could be repeated at intervals as the sensibility returned. As it was used by the medical profession for destroying cutaneous nævi, he thought it might be useful for destroying the tooth pulp; but in this he had been disappointed.

Mr. J. H. MUMMERY read notes of a case of extensive alveolar abscess of obscure origin. The patient, a strong, healthy-looking young man from Natal, had suffered for more than a year from constant purulent discharge from an opening below the angle of the jaw on the right side, which was a source of great annoyance to him. He had consulted several surgeons, one of whom sent him to Mr. Mummery with a request that he would remove the necrosed roots of the right lower first molar. This was done, but did not affect the abscess. The second molar had a small cement filling, but was to all appearances healthy, as also was the third molar. Six months later the patient returned in the same condition, and now consented to a further examination of the second molar, which was, however, still firm, and free from tenderness or percussion. On drilling into the pulp cavity, pus escaped, the tooth was at once extracted, and the sinus healed within a week, and a complete cure effected. The patient stated that the tooth had cost him between £400 and £500 in travelling expenses and surgical fees.

Mr. BETTS then read a paper entitled "Observations on the Teeth of certain Rodents," in which he disproved the statement of Professor Hilgendorff, since copied into other works, that the incisors of the Leporidae had a complete investment of enamel, and showed that the thin transparent layer at the back of the incisors of hares and rabbits was really continued from the cementum and could clearly be demonstrated not to be enamel. Although apparently a small matter, it was of more importance than appeared at first sight, since this supposed fact had been held to show that the Leporidae were in this respect a missing link between the rodents and other mammalia, whilst in reality the exact relations of this large class to the rest of the animal kingdom must still be considered an open problem.

The result of Mr. Bett's observations was confirmed by Messrs. A. Underwood and Chas. Tomes, who also commented on the obscure zoological relations of the Rodent class, and the latter suggested that some of the missing links might yet be supplied by a careful study of the marsupials.

The Society then adjourned.

THE ANNUAL GENERAL MEETING OF THE FELLOWS OF THE IRISH COLLEGE OF SURGEONS,

Which had for a couple of months past been looked forward to as the probable occasion for an arraignment of the Council by a section of the provincial Fellows, took place on Saturday, May 31st, and passed off, on the whole, much more quietly than was anticipated. The attendance of Fellows was not very large, the provincial members being especially sparse in number.

The notices of motion, which had been circulated beforehand, were four in number, and to them the entire debate was confined. Dr. Molony, of Tulla, proposed the following motion:—

"We, the Fellows of the Royal College of Surgeons in Ireland, assembled at the annual meeting of the College, hereby declare that, in our opinion, the Medical Acts Amendment Bill at present before Parliament is wrong in principle, and would, if enacted, be injurious to the public welfare, and destructive to this and similar institutions which are engaged in an earnest and successful endeavour to maintain a high standard of professional education. We, therefore, request the incoming Council to use every means in their power to prevent the enactment of said Bill."

Before Dr. Molony concluded his observations on it, he saw good reasons for modifying it so that it declared for opposition only in case the amendments sought by the Council were not obtained. Even in this modified form the motion was not acceptable, and it was eventually withdrawn in favour of an amendment by Professor MacNamara—

"That this College thoroughly disapproves of the proposed Medical Bill as it now stands before Parliament, and hereby recommends its incoming Council to oppose it by every constitutional means in their power, unless its provisions be amended in such a manner as the Council may consider necessary to the interests of the College."

The Fellows are to be congratulated on thus tardily accepting the advice offered to them at their last general meeting, and we trust that the hindrances to conciliation and compromise which were then raised up by their unwise attitude of neck-or-nothing hostility to the Bill will not prevent the College from obtaining the alterations in the measure which are necessary for the College interests. These alterations are practical and consistent with the recommendations of the Royal Commission. Moreover, they are just in principle, and accordant with the interests of the public as well as those of the College. The new Council will need to act with vigour, and by every constitutional means, and we are confident that they will yet secure the College against the injury which many expect to accrue from the Bill as it stands.

The first was moved by Dr. Tagert—

"That we disapprove of and condemn the conduct of the outgoing Council, in so far as it neglected to take the steps necessary for giving effect to the resolution of the College, passed without a division on 4th of June, 1883, recommending that the Fellows shall, in future, have the right of voting *in absentia*, by means of voting papers, for President, Vice-President, and Members of Council; such neglect being a practical ignoring of the expressed wish of the Fellows at large, and especially detrimental to the Provincial Fellows."

The second by Dr. Brunker—

"That the necessary steps should be taken by the incoming Council to have such alterations made in the Charter of the Royal College of Surgeons of Ireland as will enable Provincial and other Fellows of this College to vote at the election of the President, Vice-President, and Council, by voting papers or otherwise, as in the case of Trinity College, Dublin, the University of Edinburgh, and other institutions; and that it is expected and desired that the incoming Council shall, as one of their earliest acts, cause the above desire of the College to be carried into effect, and

will not permit any other proposal to interfere with or retard the same."

The second and third resolutions were censures on the Council, full of sound and fury, for having omitted to carry into effect last year's resolution of the Fellows with reference to voting by papers. We need not trouble our readers with a narrative of the *casus belli* of these resolutions; suffice it to say that, after much effervescent oratory, the Fellows were satisfied that the Council had not been guilty of the neglect, and had not been influenced by the personal motives attributed to them, and accordingly the resolutions were withdrawn in favour of an instruction to Council to carry the paper voting resolution into effect as soon as circumstances permitted.

The last resolution was one moved by Dr. Martin, of Portlaw, and seconded by Dr. Jacob—

"That the College regrets that its repeated recommendations to the Council to make arrangements for the more frequent and complete publication of the Proceedings of the Council have not been carried into effect; and it, therefore, again declares its desire that, without avoidable delay, provision shall be made for the issue to the Fellows of a *précis* of the Proceedings of the Council at least three times in the year, such *précis* to contain all motions and amendments of importance, together with the names of proposers and seconders, and of the votes of Councillors thereupon, in case a division has been taken. That the Council be requested, on the first occasion on which they communicate with the Fellows at large, to report to them the steps (if any) which they have taken to comply with the desire herein expressed."

Upon an explanation by Dr. Kidd, that the Council was engaged in carrying out the wishes of the Fellows in this respect, the resolution was withdrawn on the understanding that the Council would, without delay, complete the requisite arrangements.

THE ELECTION OF THE COUNCIL

took place on the Monday succeeding the general meeting, and was rendered specially interesting by the efforts of the party who had moved the foregoing resolutions to make their mark upon the new Council by removing those who were against the paper-voting project, or in favour of the Medical Bill, or otherwise associated with reform in the College.

It was rumoured that a coalition had been made for this purpose, and had been at work canvassing the Fellows for some time before the election. Dr. Jacob having declared himself hostile to *absentia* voting, and an advocate of the principles of the Medical Bill, and having made himself prominent in attacking the night-lecture sham certificate system, had the honour of being made the special object of attack, while Dr. Thornley Stoker, as a reformer and a Professor in the College, was also singled out by the private school party and the anti-Medical-Billists to be "removed." Several candidates were selected to run against those members whom it was desired to ostracise, amongst whom were Drs. Tagert and Bellew Kelly, as representing the provincial paper-voting party. Mr. Stokes, Dr. Carte, Fitzgibbon, Alcock, Nixon, Meldon, and Elliott, were also in the field as new candidates, while all the outgoing Councillors, save Mr. Butcher and Dr. Denham, sought re-election.

The result of the poll showed that the paper-voting party had failed in their enterprise, their two special candidates having scored respectively 48 and 43 votes, the minimum number to secure election being 66. Their co-operation had, however, enabled the other parties to the coalition to effect a part of their purpose by removing two of the Councillors, Mr. Thornley Stoker and Dr. Macnamara.

Mr. Stokes and Dr. Elliott, Dr. Carte and H. Fitzgibbon, were elected, and Dr. Jacob held his seat, beating the leading representative of his assailants by one vote. His poll, it is believed, would have been considerably higher but that a report was industriously circulated amongst the Fellows that he had retired from the contest, upon which certain of the voters removed his name from their lists.

Mr. Thornley Stoker, we feel bound to say, is a great loss to the College executive, and the Fellows have been badly advised in voting against him. He was one of the most industrious and intelligent of the Council, and by his votes and speeches always showed himself to be above personal considerations, animated by high professional principles, and sincerely anxious for the welfare of the College.

Sanitary Department.

SUPPLEMENT TO THE TWELFTH ANNUAL REPORT OF THE LOCAL GOVERNMENT BOARD.

[SECOND NOTICE.]

IN the Vaccination Officers' Returns, the various percentages of children not accounted for as to vaccination are given. Thus, of counties, Leicestershire shows the highest percentage (11·7), and Carmarthen the lowest (1·4). Shoreditch is the highest of the metropolitan unions, with 12·2. Of provincial towns, Keighley (63·4), and Leicester (21·2), show an undeniable prominence, Banbury (15·7) and Dewsbury (16·8) following closely.

An abstract of the medical inspections and inquiries into local outbreaks during 1882 is given, and consists chiefly of investigations into the incidence of enteric fever and diphtheria, though also comprising conditions of scarlet fever prevalence, and questions of sanitary administration; many interesting points are brought out in the epitome of the chief facts reported.

ANIMAL VACCINE.

An interesting account of the operations of the Animal Vaccine Establishment is contributed by Mr. Shirley Murphy. A description of the plan and construction of the premises in Lamb's Conduit Street is given, from which, amongst other things, it seems that each calf has a floor space of 36 feet, and that an isolation stable is provided. After February 1883, the calves were subjected to detention in quarantine in Somers Town, owing to the prevalence of foot-and-mouth disease in London, the result being that no illness had been introduced into the station. The lymph was obtained from Bordeaux originally, and started from the 17th in succession. Mr. Murphy makes the observation that the character of the vesicle is influenced by the weight and sex of the calves, the light weights and females producing the best. The insertion-succes, average diameter of vesicle, and extent of areola were found to be practically the same with animal as with humanized lymph; occasionally it was necessary to revert to lymph from an earlier calf than that immediately antecedent.

Notes are given as to the laws regulating vaccination in 18 European countries, from which it is seen that the operation is directly compulsory in 7, not directly in 11, compulsory in the army in 6, in the navy in 4, on school-children in 5. Re-vaccination is compulsory generally in 4 countries, in the army only in 3.

DR. CORY'S SYPHILITIC AUTO-INOCULATION.

The Report of the Committee appointed to investigate Dr. Cory's syphilitic auto-inoculation is given, from which it is seen that Dr. Cory had previously attempted on three occasions to inoculate himself with syphilis. In the first case there was no skin eruption or active symptom of the disease, though hereditary syphilis was diagnosed, and the vaccination was successful; in the second, the child had a coppery eruption and "snuffles," and the vaccination was unsuccessful; in the third the symptoms were subsiding under mercurial treatment, and the vaccination did not succeed. In the fourth case, the child was in an active stage of the disease, with an eruption and sores, and again the operation did not succeed, but a papular syphilide showed itself on the 21st day at the seat of inoculation, and a secondary general eruption subsequently appeared. In all these experiments admixture with blood was carefully avoided, and the result of the fourth experiment shows that it is possible to communicate syphilis from a vesicle on a syphilitic person, even if no blood be used. Attention is drawn by the Committee to the fact that all these cases

were obviously syphilitic, and by Dr. Buchanan in an appended note to the fact that two important vaccination rules were intentionally discarded, viz., to take lymph from subjects in good health, and to examine for skin disease and hereditary syphilis.

DIPHTHERIA OUTBREAKS.

Mr. Power's exhaustively minute inquiry into the prevalence of diphtheria at Pirbright was directed chiefly to examination of the school influence in its causation. The sanitary condition of the place was first examined and absolved from blame, and it was soon seen that minor cases of sore-throat, as well as true diphtheria followed by paralysis, had to be taken into consideration. The distribution of throat illness in time showed it to fluctuate directly with the several re-openings of the school, and its incidence to be confined mostly to children under 15 years. But, as the age 3—15 predisposes to diphtheria, differentiation had to be made between this age-influence and school-influence proper. Thus, it was found that the highest percentage of attacks in invaded families was amongst those from 3—12, and that the bulk of first sufferers in families were also of this age. The child of 3—12 was, therefore, apart from its age, pre-eminently the one to suffer and to bring it home. Moreover, children of this age who were attending school were affected five or six times as often as children of the same age who, during the same period, were not attending school. Further, the attacks and deaths at the foregoing ages were much greater during periods of school-opening than closure, and during the former were almost entirely amongst those who had attended school until taken ill. Hence the conclusion was arrived at that school-conditions had played the chief part in the incidence of the disease in children from 3—12. The sanitary circumstances of the school were found free from fault, and no reasons were found to uphold the suggestions that infection was introduced by convalescents, or that the disease was established by "progressive infection," or by non-recognition of mild cases of so-called "cold." Mr. Power concludes his masterly analysis by a reference to the capacity of minor trivial sore-throats in families of young children to breed malignant diphtheria, and a suspicion that such breeding may have gone on in Pirbright School.

SCARLATINA.

The same inspector's investigation into a sudden outbreak of scarlatina in Bloomsbury during January 1882, showed that the incidence was confined to the customers of a particular milk-seller, those supplied by other dairies escaping. It was found that some of the dairyman's customers received their milk from Charing Cross Railway Station before it had entered the shop, and that these had suffered synchronously with those supplied from the shop. Again, milk from the same farm had been sent to a dairy in Peckham, and distributed to people in Camberwell, who afterwards suffered from the disease. Further, some of this same milk, purchased by railway servants at Charing Cross, had attacked thirteen persons at the same time as the St. Giles and Peckham customers, whilst no outbreak was noticed amongst the railway people at Waterloo, where such purchase is prohibited. So that it was apparent that the milk owed its infection to the farm; and, failing to discover any source of human infection, Mr. Power was led to the hypothesis that some element of animal infection had been introduced. Relying on the relation between scarlatina and puerperal fever, he suggests infectiveness of the milk of a recently delivered cow, either from the system or lochia. As facts worth recording in connection with milk outbreaks, he notices (1) the short infectivity of the milk; (2) that the

businesses from which the milk comes are concerned only with milk (not butter or cheese), and not with calf rearing—hence, the cows would speedily return to work after parturition; (3) that milk scarlatina has a lower mortality, is milder, more localised to the throat, and less able to spread than the ordinary form. The facts, he contends, are not inconsistent with an animal origin. Mr. Power's ingenious hypothesis was made the subject of experiment by Dr. Klein, who, whilst failing to induce illness in animals fed with the lochia of a healthy cow, yet succeeded in transmitting to a cow inoculated with human scarlatina a disorder which was further transmissible to dogs. The lochia of a recently-calved cow, that had been inoculated and fed with human scarlatinal throat discharge, and had developed a local abscess only, added to some of its milk, were introduced into the tissues of dogs, pigs, and guinea-pigs, with the result of producing swelling and inflammation of the throat and ulceration of the tonsils, as well as caseous enlargement of glands.

(To be continued.)

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, JUNE 11, 1884.

REJECTING THE YOKE.

AN intense feeling of relief has been experienced throughout the profession at the action taken by a majority of the Fellows of the Royal College of Physicians of London present at the extraordinary meeting held on May 29th. On this occasion, the Council of the College, according to custom, presented a list of those to recommended for election to the Fellowship, in the expectation that, as heretofore, it would receive the unquestioning assent of those assembled. For once,

however, this trust was rudely shaken; and on the motion of Dr. Andrew, seconded by Dr. Sieveking, the list was declared by a large majority of Fellows present to be unsatisfactory, and was then and there remitted back to the Council for amendment.

Such a determined assumption of their due rights by the proper rulers of the College ought to have a salutary effect on the Council, by proving to its members that they do not form an irresponsible oligarchy, as seems to be their impression, if we may judge from evidence afforded by their past actions, and that they are liable to incur the displeasure of their constituents by neglecting the claims that should influence their selection of candidates for the highest diploma of the College. For a long time past a feeling of despair has taken possession of those who look for the exhibition of a real spirit of anxiety for general professional advancement on the part of the Council of the Royal College of Physicians; and now that the whole body of Fellows have evinced a decided intention of provoking the reforms essential to the preservation of the prestige of the College, a most welcome sensation of relief pervades the profession, by which this first sign of revolt will be accepted as an indication of approaching wholesome and thorough change.

The immediate effect of this rebellion of the Fellows will no doubt be felt as a hardship to those whose names were proposed for the coveted distinction of F.R.C.P.; but we may very well consent to the sacrifice they must undergo, if by it the principle of merit is made to assume its rightful place in determining the choice of the Council. A study of the lists of recently-elected Fellows affords a melancholy illustration of the proneness of officialism to favour the claims of mediocrity, when untrammelled by free criticism and direction from those whose right it is to criticise and direct. A correspondent declares in another part of our present issue that only nine Fellows out of the thirty-nine last elected can be said to be well-known professional men, and this, notwithstanding that deserving names have been passed over year after year by the Council of the College. If the Fellowship is to hold its own as a symbol of professional eminence, then it is clear that of late years the Council has failed in its duty, by proposing for election many by whom the honour is undeserved so long as others more deserving than they remain without the pale of Fellows; and that this opinion is entertained apart from the Council, in the College itself, is sufficiently shown by the decided refusal of the latter to accept the Council's nominations for the present year.

This occurrence at the Royal College of Physicians offers a striking illustration of the differences which exist between it and the Royal College of Surgeons, as regards the powers possessed by the Council. Had the same conditions obtained at both institutions, the selections made by the Council of the College in Pall Mall must have been acquiesced in by the Fellows, who could not have done that which they recently did, or refused to sanction the act of their Council. As we have lately been engaged in showing in these columns, whatever is done by the Council of the Royal College of Surgeons is done by an irresponsible and uncontrolled committee; the general body of the College is neither consulted as to the advisability of particular acts, nor required to

confirm them when about to be carried out. It is not at all improbable that the time may come when the executive of this corporation will commit an error as distasteful to the Fellows as that into which the sister College's officials have just fallen; but so long as the present constitution of the College of Surgeons is continued there will be no force capable of controlling its Council, however extravagant the proceedings in which they indulge. That a grave injustice to the profession has been prevented at the College of Physicians by virtue of the subjection of the Council to the *comitia* of Fellows, is a matter for deep congratulation. Apart from the immediate and remote influence on the College itself, this act will have an important bearing on the attitude of all those who are engaged in a struggle with the unyielding few who form the Council of the Royal College of Surgeons. It provides them with an argumentative weapon the utility of which can scarcely be overestimated, for it shows at once how prone private interests are to usurp public welfare, and how vital it is to preserve a power of defence against possible violations of unwritten law.

All will desire that, having once manifested their strength, the Fellows of the College of Physicians will not rest content with what they have done, but will compel the pursuance of reforms that have long been decided to be essential in the interests of Medicine. Indeed, the whole profession will anticipate this sequel to the motion of Dr. Andrew, and will be grievously disappointed should no such consequences ensue as its result.

THE NEW BANKRUPTCY ACT IN RELATION TO ARTISAN PRACTICE.

To the poorer tradespeople and the artisan classes the New Bankruptcy Act is not likely to prove an unmixed blessing. To a certain extent they are bound to live on credit, and anything that serves to shake confidence in the soundness of their credit must increase their difficulties in securing the necessities of life. The working of the Act is especially prejudicial as regards the relations between these classes, and medical men. The poorer classes, out of their regular income, or the weekly wage, are able to make provision for all ordinary expenditure; it is the unforeseen or extraordinary that compels them to draw upon their credit for existence. In the case of the working man, in addition to want of work, which of course leads to a credit expenditure without revenue, the main source of unforeseen expenditure lies in the strain caused by sickness, which seems never to be anticipated or provided for. It would be simply an impossibility for a working man to pay cash down for medical attendance in the course of a sharp illness, necessitating daily visits or even visits twice a day. This being so, credit is absolutely necessary, payments being made in small instalments spread over an extended period. This system has, hitherto, worked fairly well in the case of the industrious and honest-minded working man, who is both willing and anxious to discharge his debts, and who, up to the present, has received encouragement to persevere in doing so, in the

knowledge that the opposite course was not a bed of roses for those who followed it, owing to the legal proceedings that might be taken in the event of prolonged default. On the whole, we think it may be fairly claimed for medical men, that they have, as a rule, been long suffering and patient in their dealings with the poor, and that they have been careful to avoid harsh measures in the case of those, of whose honesty and desire to pay they were satisfied, but who were unable to do so from the force of surrounding circumstances. As a rule, legal proceedings are only put in force as a last resource. The honest and thrifty folks find no difficulty in meeting their doctor's claims. It is only the wilfully dishonest, the thoughtless, or the drunkard and spendthrift that come to grief and appear in court, and who, through the teachings of experience, find, that on the whole, proceedings in court afford them a chance for the evasion of their debts as so few care to follow a case out to the bitter end by selling the home up under an execution order. At present, the application for "administration orders" is steadily increasing. In a great number of these cases, medical men's accounts appear as a very large proportion, often over half the whole amount of the debtor's liabilities; giving rise too frequently to unfavourable comments on the part of the judges. Indeed, these comments are often made in such a manner as to cast a slur upon the profession, making it appear discreditable for the doctor to have allowed his patient to run on such an account. It seems, in such cases, to be almost a pleasure to the judge to reduce the amount and to order its payment to be made by very small instalments each court day. No allowance seems to be made for the length of time over which the attendance has extended, nor the amount of work which has been performed. No consideration appears to be shown for the position of the medical man, who finds it difficult to refuse his services, however shaky he may know the financial position of his patient to be. If it is the father of the family—the bread winner, who is ill, all earnings cease at a time when expenditure is necessarily increased in the effort to provide proper food and other comforts for the patient. If the medical man refuses to attend, he is regarded as hard of heart and wanting in the feelings of humanity, his conduct being severely criticised by the neighbours, and his reputation suffering to a greater or lesser extent according to the surroundings of the case. If it is the wife or children he is still called upon at a time, when there is necessarily an increased strain upon the resources of the household, and when it requires all the man can make to keep things square; under such circumstances, it would be a matter of considerable difficulty for the father to pay the medical man ready money, and it would be looked upon as a great hardship if the latter were to refuse his services.

It will be impossible, however, for medical men to continue the credit system of attendance, if those who are indebted to them avail themselves largely of the facilities under the New Bankruptcy Act, for the evasion of payment of the greater part of their debt, and the slow discharge of the amount they are ordered to pay.

For example, A owes altogether £40 of which £15

may be due for medical attendance extending probably over five or six years in some cases, or, if the illness has been a very severe or prolonged one, the debt may have been contracted in four or five months upon the one case. A applies in the Court of Bankruptcy or County Court, for an "administration order." The judge reduces the gross amount one-third or one-half, i.e., to £27 or £20, and directs payment to be made by instalments of 6s. to 8s. each court day, that is, per month. This means that at the end of seven years and a half, the doctor may hope to receive two-thirds or one-half of his account where the total amount has been reduced, and the instalments ordered amount to 6s. each court day. This is not encouraging to trustfulness on the part of medical men, and must, in time, lead them to refuse their services unless paid at the time the services are rendered, in all cases where there is the slightest doubt of the patient's honesty or solvency; and thus a real hardship will be inflicted upon many a poor family, who, under present circumstances, can command proper medical attendance in the time of sickness.

Unless carefully administered, with a due regard to the interests of the creditors, and acting upon the clearest proof that the position of the debtor was in no way due to his misconduct the working of this Act is likely, by shaking confidence in their credit, to increase the difficulties of living for the poorer classes, who will suffer for the misdoings of those who are dishonest enough to avail themselves of the Act, for the evasion and slow discharge of their just debts.

Notes on Current Topics.

A Fresh Chance for the Antivivisectionists.

It was to be expected that those whose business it is to maintain the antivivisection agitation would seize the opportunity afforded by M. Pasteur's expressed intention of proving his latest conclusions by aid of experiments on living animals. As, however, there seemed but little likelihood of affecting the French people from this side of the Channel, the agitators determined to make their charge in the full front of Parisian Society; and accordingly a meeting was held on Friday with the avowed object of organising an "International Congress," the effect of which is presumably intended to supplement Mr. Jesse's "total abolition" schemes. Miss Anna Kingford, whose declamations against scientific progress are familiar to every student of crazes whose interest extends to a perusal of the literature relating to them, occupied the post of orator on this occasion, and her arguments were at once instructive and refreshing. Because hydrophobia is a "very rare" disease, this lady concludes that M. Pasteur is not justified in "torturing thousands of animals with the object of abolishing the disease." There is, fortunately, nothing original in the ignorance and inhumanity of this declaration. It has been made in similar terms a thousand times before, and probably will serve to tickle the intelligence of unthinking crowds as many times more. But, nevertheless, it is a gross misstatement as regards, at any rate, the particular case in point. The "thousands of animals" is an antivivisectionist's

phrase for forty dogs, twenty of which only will suffer under the experiment to be tried; while the other part of the statement, to the effect that it is not justifiable to reduce human suffering through discoveries by physiologists, can appeal to none but the intolerant and bigoted. It is useful to know that antivivisection is not entirely a dead and gone delusion; although at the same time it is humiliating to think that some presumably educated men and women, few as they may be, can be found to listen to its supporters.

Another Patent Medicine Victory.

ONE more death attracting public notice is to be credited to the Patent Medicine Act, the victim this time being a little girl twelve months old. At the inquest held on the body, and presided over by Dr. Danford Thomas, coroner for Central Middlesex, it transpired that the unfortunate infant had been dosed with patent medicine, the effect of which had been to hasten the fatal event. Dr. Thomas very properly judged the occasion one to call forth a decided expression of opinion from him, as to the terrible injury inflicted on the community from the absence of any restrictions on manufacturers of widely-advertised secret remedies for a thousand ills, and which, at the untrammelled will of the maker, may or may not contain even the most deadly poisons. The coroner further expressed a hope that before long the law would be altered so that persons would have to make known the contents of each patent medicine before selling it; and the jury, in returning a verdict in accordance with the medical evidence, expressed their disapproval of patent medicines being given to children without medical advice.

The City Coronership.

THE date fixed for the election of a new coroner for London City, in succession to the late Mr. W. J. Payne, is to-morrow (Thursday), and the number of candidates for the office is fourteen. But one of these gentlemen—Dr. Wynn Westcott—appears to us to combine in himself all the necessary qualifications to be desired in a responsible officer like that of coroner for so important a centre as the metropolitan city; and we cordially trust the choice of the electors may fall upon him. Our knowledge of Dr. Westcott is entirely derived from his public life, but it is of a kind to lend assurance to the belief that he is especially competent to carry out the magisterial duties associated with the post he is seeking; while at the same time his professional position entitles him to the sympathies of all who recognise the close connection between inquiries respecting the cause of death and a technical knowledge of the laws which regulate the relations of life and disease.

Some surprise was created by the announcement, made by a prominent opponent of Dr. Westcott's, to the effect that "the staff" of Charing Cross Hospital had written a letter of congratulation to the former on his appointment to the Coronership of the City of Southwark, and expressing a wish for his further success in the competition for the greater office. On the part of the hospital staff, a public denial of the letter was made, and then it transpired that "the staff" consisted of the senior students resident in the hospital, and holding the posts of house-physician,

house-surgeon, and maternity officer respectively. The mischievous intervention of these young men in a question of City politics cannot be excused on any ground whatever. If it arose from a silly desire to bring their names into prominence, it shows a contemptibly boyish spirit of conceit; while if it was, as appears most probable, suggested to them, then they have exhibited a painful lack of discretion in responding to the appeal without first consulting with their seniors and teachers on the staff of the institution to which they are attached. Though no one possessing any knowledge of hospital administration would be for a moment led away by the letter of these youths, still the uninformed public, especially when told that it emanates from the "staff," cannot be supposed to discriminate between it and *bonâ fide* testimonials from persons of position and judgment; and in this way the cause of other candidates unpossessed of similar meaningless credentials is likely to be detrimentally affected by the action of a few students at a London hospital. It is to be hoped that on the real facts of the case becoming known, the real meaning of the letter may be apparent to the electors, and duly appraised by them.

Medical Advertising.

IN a recent issue of the *Times* newspaper a letter appeared from Mr. Richard Barwell, F.R.C.S., Surgeon to Charing Cross Hospital, the occasion for its production being given by the dynamite explosions of Friday week last. Several of the injured persons came under Mr. Barwell's care in the hospital, and he very properly satisfied public anxiety by contributing to the principal lay journal an account of their condition, written in a way to be generally understood. With this proceeding no fault is to be found; but when Mr. Barwell goes on to discuss a surgical problem in the latter part of his letter, it seems to us that he exceeds the proper bounds to be observed by a surgeon in communications addressed to the public press. Further, also, he incurs a wholly unjustifiable responsibility by taking on himself to prognosticate in one case, that of a girl, that the ultimate effects of the shock she experienced will not in any way interfere with her well-being, and on the text thus provided, to pursue a line of discussion such as ought by right to be followed only in a paper designed for professional readers. In the present state of disturbed feeling respecting advertisement of themselves by medical men, those who hold an assured position in the profession should be especially careful to avoid every appearance of the weakness attributed to such as said to offend; and Mr. Barwell may not improbably be held to have exposed himself to the charge hurled against others.

MR. LAWSON TAIT has accepted an invitation to deliver an address in "Abdominal Surgery" to the Canada Medical Association at Montreal on August 25th.

THE 500th anniversary of the foundation of the University of Heidelberg will shortly be celebrated. The sum of £8,000 has been voted by the Baden Parliament to defray the expenses.

The Collection of Refuse.

THE Vienna authorities have recently adopted a new method of collecting refuse that one would think cannot fail to commend itself to our own governing bodies, although whether they will find imitators amongst us is quite a different matter. The new Vienna method is based on the assumption that infective matter is not unfrequently mixed with dust, sweepings, and rubbish, and that by transporting such rubbish on open conveyances there is at least a possibility of disease being disseminated along the route of conveyance. The method consists in having all refuse put into barrels provided with tightly-fitting heads. These barrels are then collected, carted away to the proper locality, emptied, disinfected, and then returned. In order that every household may keep his own, the name and address of the owner are painted on each barrel. The Vienna authorities are making a valuable experiment, and if it proves successful and not too expensive other municipalities will not be long in following so good an example.

Scarlet Fever in Wigan.

SCARLET fever has been epidemic in Wigan for the last eight months, and measles also has become prevalent, in consequence of this, and also previous unsuccessful efforts to stop the spread of these infectious diseases, Mr. Barnish, the medical officer of health, has felt compelled to recommend to the Sanitary Committee of the Town Council that all elementary schools, as well as Sunday schools, should be closed for a period of five weeks. The Committee have served notices on the managers to close them at once for the period recommended. Some opposition was met with from three schoolmasters and school managers who will lose in school pence probably to the extent of £7 per week for each school, but as the health officer ably showed the loss is small (considering that 162 deaths have already been caused by scarlet fever) in comparison with the prevention of the spread of such infectious diseases as scarlet fever and measles.

Milk-Scarlatina and Cow-Disease.

MR. POWER's hypothesis as to the possible relationship between scarlatina and disease of the cow, particulars of which will be found under the heading of our Sanitary Department, marks an era in etiological pathology.

Mr. Power, whose analytical talent is so well established, traces the causation of the particular outbreak to the farm, and eliminating human infection from men or things (which has formerly done ample duty as a cause), boldly attacks the problem whether any or all of the conditions of what may be termed a lying-in cow may not supply the infective link or links required. He inquires whether it may not be possible that a perverted secretion on the one hand, or a local admixture of lochia from a soiled udder on the other, should suffice to envelop the milk with its specific power to cause scarlatina, and reminds us of the causation of puerperal fever by the exposure of parturient women to the virus of zymotic disease. Now, this latter is true enough; but the analogy between the occasional causation of puerperal fever by, say, scarla-

tina, and that of scarlatina by cow-disease, seems scarcely strict enough to warrant further inductions, inasmuch as puerperal fever is not to be compared with scarlatina in point of specificity. To establish the hypothesis, it would seem necessary to prove that a newly-calved cow suffers, under certain conditions, from a disease analogous to human scarlatina, either autogenetic, or derived originally from human infection. Dr. Klein's experiments, though not conclusive, seem to point in this direction; and in the meantime, whilst awaiting further researches, we commend the matter to the attention of our veterinary *confrères*.

The Stewart Scholarship.

SOME months ago we noted that the bulk of the property left by Dr. Stewart, of Dublin, had been appropriated by the Master of the Rolls, Sir Edward Sullivan, to a purpose with which the deceased had never shown the slightest sympathy, to the exclusion of those objects with which the efforts of his life had been associated. £30,000 of the money of this benevolent gentleman were thus handed over to be divided between the University of Dublin and the Royal Irish University, neither of which institutions either needed or cared for the money, for the purpose of founding literary and medical scholarships. With regard to these scholarships in the Royal University, its Senate has adopted the following regulations. One scholarship of the annual value of £50, tenable for three years, will be offered in the autumn of 1885 for competition among medical graduates of not more than two years' standing, for proficiency in mental diseases. A second medical scholarship, of the annual value of £10, tenable for three years, will also be offered in the autumn of 1885, for competition in the subjects of the second examination in medicine. In order to be eligible, candidates must present themselves after the lapse of not more than one academical year from the time of passing the first examination in medicine. A scholarship in arts, of the annual value of £30, tenable for three years, will be awarded at the autumn examinations of 1885 to the candidate who will be found to have obtained the highest aggregate of marks upon taking into account the marks obtained at the honour examinations in English and in a modern language at the first university examination in the present year (1884), and at the second university examination in arts in the year 1885.

International Conference on Education.

THE Executive Council of the International Health Exhibition having decided to hold an International Conference on Education in connection with the Educational Division of the Exhibition, they have appointed a Committee of Management, who have drawn up a detailed programme of subjects for discussion, all papers in which will be printed beforehand, and these will subsequently be published by the Executive Council. Persons desirous of attending the Conference are invited to send in their names to Mr. R. Cowper, Secretary to the Committee of Management, International Health Exhibition, South Kensington, to whom any inquiries can be addressed.

The Conference will be opened on Monday, the 4th of

August, at 11 a.m., and will continue throughout the week. The subjects for discussion are arranged under eleven heads, and are as follow:—1. Conditions of healthy education. 2. Infant training and teaching—*a.* kindergarten; *b.* instruction generally. 3. technical teaching—*a.* science; *b.* art; *c.* handicrafts; *d.* agriculture; *e.* domestic economy. 4. Teaching of music in schools. 5. Museums, libraries, and other subsidiary aids to instruction in connection with schools. 6. Training of teachers: under this head will be considered the right professional preparation for teachers in—*a.* elementary, *b.* intermediate and higher, *c.* special and technical schools. 7. Inspection and examination of schools—*a.* By the State; *b.* By the universities; *c.* By other public bodies. 8. Organisation of elementary education. 9. Organisation of intermediate and higher education. 10. Organisation of university education. 11. Systems of public instruction in various countries.

Fellowships and Examinerships in the Royal University of Ireland.

AT a meeting of the Senate of this University last week, Dr. Robert O. Cunningham, Professor of Natural History in Queen's College, Belfast, and Dr. George Sigerson, Professor of Botany and Zoology in the Catholic University College, Dublin, were elected Fellows in the Department of the Natural Sciences. The following examiners were reappointed for one year:—In medicine, Stephen M. MacSwiney, M.D.; in midwifery, John A. Byrne, M.D.; H. Macnaughton Jones, M.D.; in medical jurisprudence, E. W. Davy, M.D.; in materia medica, F. J. B. Quinlan, M.D.; J. Seaton Reid, M.D. And the Senate appointed Dr. Michael M'Hugh one of the examiners in medical jurisprudence, in succession to the late Dr. Matthias O'Keeffe, of Cork.

OUR American contemporary, the *Cincinnati Lancet and Clinic*, which has, on several occasions, done good service to the profession by the exposure of educational shams, announces in its issue to hand, that the "Medical University of Ohio" on which we animadverted in a recent number, only exists on paper, and is another of those diploma-selling swindles which flood the world with "bogus doctors." Again, on the strength of these repeated announcements, we enter our protest against the legal admission to practice, within British possessions, of the *alumni* of institutions over whose educational requirements and status we can have no possible knowledge or control.

IN the principal foreign cities the rates of mortality per 1,000 of the various populations were, according to the latest official returns, as follow—Bombay 30, Madras 89, Paris 25, Geneva 24, Brussels 20, Amsterdam 27, Rotterdam 36, The Hague 29, Copenhagen 25, Stockholm 25, Christiania 11, St. Petersburg 36, Berlin 23, Hamburg 30, Dresden 28, Breslau 34, Munich 33, Vienna 31, Prague 39, Buda-Pesth 39, Trieste 26, Turin 31, Venice 22, Lisbon 24, New York 25, Brooklyn 18, Philadelphia 19, and Baltimore 19.

The American Medical Association.

A LIVELY picture of the recent annual meeting of the American Medical Association is drawn by the Washington correspondent of the *Boston Medical and Surgical Journal*. Every society passes in its earlier periods of existence through some curious stages, and has, probably, to admit into its fellowship a few candidates for the distinction who would not at a later time be accepted as members. It may, for instance, be questioned whether the presence among them of gentlemen who, during a reception, "spent a large portion of their time in the supper room with their hats on," would be welcomed by members of our own Association; but the most remarkable incident described in connection with the American Assembly refers to the locality in which the meetings were held. This chanced to be the congregational church, centrally situate, but seemingly a building, the use of which was unappreciated by not a few of the doctors gathered together inside of it. We are gravely informed that "the janitor of the church was also busying himself by hanging up placards of 'please do not smoke in this church,' and exerting his personal influence to the same effect, which was resented as an interference by some, quietly ignored by others, while the good-natured strolled out to the front steps with their cigars." It is satisfactory to learn, after all this, that the meeting accomplished some good work, having been attended by nearly 1,300 members.

A Centenarian.

THE *Connaught Telegraph* reports the death, at Foxhill, near Ballyhaunis, of one Luke Mannion, who had reached the patriarchal age of 108 years, and who to the very last retained his mental faculties in unimpaired perfection.

The Reuben Harvey (Dublin) Memorial Prize.

THE first award of this triennial prize will be made in July, 1885, and will be open to all students of the Dublin medical schools, also to graduates or licentiates of Irish licensing bodies of not more than three years' standing at the time the award is made. The essays are to evince original research in animal physiology or pathology, and are to be illustrated by drawings or preparations.

THE *Graphic* states that, under the will of the late Mr. George Hudson, of Monkwearmouth Grange, Sunderland, the sum of £200,000 has been set aside for the maintenance, clothing, and education of orphans belonging to Sunderland. Mr. Hudson has also bequeathed £500 to the Sunderland Infirmary.

AT the last meeting of the West London Medico-Chirurgical Society, Dr. Thudichum, the President, made an announcement that an annual lecture would be delivered under the auspices of the Society, to be called the "Cavendish Lecture," in honour of the distinguished chemist who resided in the west of London, and who was an ancestor of the Duke of Devonshire, now President of the West London Hospital. Mr. Timothy Holmes, F.R.C.S., has, we understand, consented to deliver the first "Cavendish Lecture" early in July.

A Quack in Trouble.

ONE of those benevolent individuals whose impudence is only equalled by their insensate greed for money, and who, for nearly a generation past, has succeeded in amassing a not inconsiderable income by offering advice *gratis*, and nostrums at an incredible charge; a man in fact who lived for the exclusive benefit of his fellow men in advertisements, a heaven-born heal-all in theory and a fraud in practice, is just now under remand at Manchester on several charges of conspiracy to defraud. This individual, the Rev. Mr. Silverton, Baptist minister by profession, is, if we mistake not, the same who for years advertised from the neighbourhood of Nottingham his wonderful powers of cure in cases of deafness, blindness, and other trifling complaints, offering to supply his prescriptions free to whomsoever would. Gradually his *gratuitous* business has increased, until of late years the opening of an office in London was rendered a necessity, and a tour of health lectures also *gratuitous*, through the provinces was being indulged in. Here he met with a slight check in his humanitarian mission; some patients who attended these discourses paid him considerable sums to be healed of their infirmities, and failing to get what they bargained for, inconsiderately had him arrested and put to much annoyance thereby. It would be amusing, were it not so serious, to notice the credulousness of the public with these quacks. One man stated that he went to the defendant with a bad foot, he felt his pulse, told him he wanted clearing, and gave him some medicine, for which he was charged 35s. A lady also consulted him for sterility, and he gave her some medicine. The medicine in both cases was examined by the city analyst, and was found to be simply tincture of rhubarb. Detective Caminada also consulted him with a feigned rheumatism in the foot, and was given harmless cough medicine. With Silverton, unfortunately for the credit of our profession, is associated a Mr. C. Mitchinson, M.R.C.S. Eng., to whom we beg to call the attention of his College; meanwhile we anxiously await the Manchester magistrates' decision.

THE following topics for papers in the Public Health Section at the Belfast Meeting of the British Medical Association have been suggested:—1. Prevention of Epidemics; 2. Inspection of Meat Markets, with special Reference to the Causation of Disease in Man by the Consumption of Diseased Meat; 3. Over-pressure in Schools, with special reference to the Record of clinically observed Facts. Communications should be addressed to Mr. S. Murphy, 158 Camden Road, London, N.W.

DR. ALEXANDER TWEEDIE, F.R.S., whose strength had been failing for some time, died on Friday, the 30th ult., in the ninetieth year of his age.

SINCE the practical suspension of the "Infectious Diseases Act," effected by Mr. Stansfeld's motion last year, the number of syphilitic cases in the military hospital at Colchester have increased 300 per cent.

EXAMINATIONS of candidates for commissions in the Medical Department of Her Majesty's Army, Naval, and Indian Services will be held at the London University on the 11th August next, and following days, at 10 o'clock a.m. The vacancies are—Home Army 19, Indian 5, Naval 24.

THE first of Sir Henry Thompson's lectures on Some Important Points in connection with the Surgery of the Urinary Organs, will be delivered at the Royal College of Surgeons on this (Wednesday) evening, June 11th, at 4 p.m.

WE understand that Dr. Hare Philipson, Newcastle-upon-Tyne, Professor of Medicine in the University of Durham, has been appointed to deliver the annual Bradshawe lecture at the Royal College of Physicians, London, August 18th.

The Coming Election at the Royal College of Surgeons of England.

THE annual election of Fellows of this College to fill the five vacancies at the Council board will be held next month, and already several candidates are in the field. These include Messrs. Barwell, Gant, Durham, Lawson, Cowell, Berkeley Hill, and Pemberton. In addition to these, Mr. T. Smith, one of the retiring candidates, will seek re-election. At this stage of the contest we can do little more than name the candidates, but it will be proper to express the hope that electors will not fail to remember the duty that rests with them of returning those gentlemen at the head of the poll who are supporters of the contemplated necessary reforms. This platform is assumed by more than one of the candidates named, who sympathise with the movement to give all Fellows of the College a proper share of its government, and we trust that these liberal views will rule the coming election.

The Appointments held by the late Dr. J. Stannus Hughes.

THE lamented death of the late Dr. J. S. Hughes, has set free several appointments of some value in Dublin. The Professorship of Surgery in the Royal College of Surgeons is already the subject of competition. Mr. Hamilton, formerly Lecturer on Surgery in the School of Stevens's Hospital, has declared himself a candidate, and being long associated with the College and well-known as an experienced teacher and a distinguished practitioner, his claim is fully recognised. Mr. Corley, the Vice-President of the College, Lecturer on Surgery in the Carmichael College, and Surgeon to the Richmond Hospital, will also probably offer himself, and other candidates, as yet undeclared, will no doubt submit their claims.

THE office of Surgeon to the Vice-Regal Household also held by Dr. Hughes for so many years is worth nominally £100 a year, but actually much more. It is in the hands of the Lord-Lieutenant, free of all political influence. Dr. Mapother, Surgeon-in-Ordinary to His Excellency, and Dr. Lentaigne, Surgeon to Jervis Street Hospital, are both named as likely to be selected for the office. The Secretaryship of the Council of the Irish College of Surgeons, held by Dr. Hughes for no less than twenty-six years, has already been filled, it being, as will be understood, impossible for the Council to proceed with the College business until it was provided with a recorder of its proceedings. The election took place on Thursday last, when five candidates offered themselves,

viz, Drs. Minchin, Tweedy, C. H. Robinson, Pratt, and Jacob. Dr. Jacob was selected, and has entered on his duties.

By his acceptance of office he vacates his seat on the Council, and an election thereto has been fixed for Monday, 23rd, at 1 p.m. We understand that Mr. MacNamara, representative of the College in the General Medical Council, will offer himself to the Fellows for the vacant office.

The death of Dr. Hughes also vacates the Surgeoncy of Jervis Street Hospital, and an Examinership in Lunacy under the Court of Chancery.

AT a meeting held in Chester on Friday last in connection with the election of candidates for the Royal Albert Asylum, the Duke of Westminster said that in the seven northern counties which the asylum covered there were 8,000 idiots, of whom about 2,400 are between six years and 25 years of age.

WE congratulate that most able and indefatigable officer, Dr. Rees Phillips, upon his appointment as Medical Superintendent of St. Ann's Health Asylum, which has just been erected with funds given by the late Mr. Holloway for that purpose. Dr. Phillips has for some time occupied a similar position at Woulford House Asylum, and we have no doubt the same enlightened system of treatment will be carried out at St. Ann's.

PROFESSOR PASTEUR, even in vivisectioning France, is not allowed to carry on his researches altogether in peace, and his establishment at Meudon, a suburb of Paris, has been interdicted by the Mayor on account of the noise of innumerable dogs kept by him. The distinguished *savant*, however, has human sympathisers, and already two—a medical student and a railway porter—have offered themselves for inoculation with the virus of rabies. The question whether Pasteur has elected to run the chances of being eventually tried for homicide, or to perform the experiments on conies, is as yet unsettled.

Scotland.

[FROM OUR NORTHERN CORRESPONDENTS.]

POOR-LAW CONFERENCE IN GLASGOW.—At a Poor-law Conference arranged by the City Parochial Board, held in Glasgow on the 3rd inst., Dr. Russell, the medical officer of health for the city, read a valuable paper on "Public Health and Pauperism." He pointed out that in one aspect public health became a question of profit and loss—a mere matter of book-keeping. The community must pay in one way or another, and the question came to be whether they would support the pauper and neglect public health, or expend money in general measures for the preservation of health, and so cut at the roots of pauperism, in so far as they were nourished and sustained by disease. The question of poor-rates *versus* sanitary assessment was merely a portion of the wider question of cure *versus* prevention. If the public did not prevent disease because the means of prevention could not usually be had for nothing, then they might presume that there was in the public mind a belief that disease, if it did not actually cost the community nothing, at any rate cost less than the means of its prevention. If it were, as he asserted, that not only as to pauperism, but in all its relations, health

was cheaper than disease, how was it that the public were so slow to see this? It seemed to him that it was because, while the items on the debit side of the public health ledger were direct and personal, those on the credit side were indirect and impersonal. Dr. Russell compared, in some respects, England and Scotland. In the six years, 1855-60, the death-rate per 10,000 of the population was in England 219, and in Scotland 207. In the ten years, 1861-70, it was 225 in England and 220 in Scotland. In the ten years, 1871-80, it was 214 in England and 216 in Scotland. Those figures showed that while England started in the race with a higher death-rate than Scotland, the relative position was now reversed. In all respects, therefore, England was outstripping Scotland in the business of health-seeking, for while Scotland had taken only 2 per cent. off her death-rate in the last ten years, England had reduced hers 5 per cent.

A SANATORIUM FOR EDINBURGH STUDENTS.—Professor Chiene is at present erecting a sanatorium in the Marketgate, Craik, to which over-exerted students are to be brought for rest. The house is situated next the Professor's summer residence, and consists of a double storey building, with accommodation for two or three students at a time. For the sake of the University we hope that the number of applicants will be numerous; for the sake of the students that they may be few. At any rate, this effort of Professor Chiene to place rest and health before the really hard-working student cannot be too highly commended, if commendation were possible for an act that must bring its own reward, and which at once betokens the thoughtfulness and kind-heartedness of Mr. Chiene.

EDINBURGH.—FIRE IN THE ROYAL INFIRMARY.—About half-past nine o'clock on Saturday, the 31st ult., a fire, which occasioned a good deal of alarm, broke out in one of the servants' dormitories of the Edinburgh Royal Infirmary. A detachment of the fire brigade was promptly on the spot. The firemen soon extinguished the flames, but the water found its way into the ward below, and besides causing considerable alarm among the patients, rendered the removal of them to some of the other wards necessary.

GLASGOW ROYAL INFIRMARY.—At a meeting of the directors of this institution, held on the 5th inst., the subject of filling up the vacancy caused by the promotion of Dr. Lothian was discussed, when it was resolved to make no appointment in the meantime. It is understood that some changes in the management of the dispensaries are in contemplation.

A VOLUNTEER MEDICAL CORPS FOR SCOTLAND.—Surgeon-Major Evatt, of the Army Medical Department, Woolwich, whose indefatigable exertions in the same direction throughout the United Kingdom are well known and have met with considerable success, addressed a largely-attended meeting of students and members of the profession in the New University Buildings, Edinburgh, on the 6th inst., on "Volunteer Medical Organisation, with special reference to the Objects and Aims of a proposed Hospital Corps." Professor Douglas MacLagan presided. Surgeon-Major Evatt explained, by means of a diagram, the constituent parts of an English Army Corps. It was divided into three divisions, with a cavalry brigade and a body called the corps troops; and each division was again subdivided into two brigades. He proceeded to describe the present arrangements in the army for the care of the wounded. Behind each division there was a bearer company, to which the wounded men were carried, and, if their wounds were so serious that they could not again proceed to the front, they were carried back to the field hospitals, which formed

the next line of medical relief, and thence, if necessary, to the hospitals at the base of operations, from which they were conveyed to England. We required, said Dr. Evatt, for the volunteer force medical men, who could teach the people what ambulance work meant, and they would get a hearty response from the public. The work would in no way handicap the student, for it would teach him how to attend to the injured, and in the industrial warfare going on every day—with people injured on railways and in factories—it was something to their advantage to be able to attend skillfully to such cases. Professor Chiene expressed the hope that in a large school like that at Edinburgh there would be no difficulty in forming a medical corps. With two thousand students, he thought they should have not only an efficient combatant company, but also an efficient hospital corps. He moved that a Volunteer Hospital Corps be formed in connection with the Edinburgh Medical Schools, and that a committee be appointed to make the necessary preliminary arrangements. Dr. Cathcart seconded the motion, which was carried by acclamation. Professor Turner, in moving a vote of thanks to Dr. Evatt, said that in that great school of medicine they should do something to help on the important work that had been brought before them that day.

Correspondence.

THE FELLOWSHIP OF THE LONDON COLLEGE OF PHYSICIANS.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—In your issue of Feb. 20th, I drew attention to the subject of the election, or selection, of Fellows from among the members. I there pointed out (1) that, of the last thirty-nine selected, only nine had any claims to be regarded as men well known to the profession; or men who may be said to have "won their spurs"; and (2) I gave a list of men fairly well known, who have been passed over. After that, followed some speculations as to what constituted a claim to be elected, or a cause of objection. Then followed these words:—"Something was said a little time ago about a new regulation, by which the claims of Fellows to be elected, would be enumerated when chosen; the next list will perhaps indicate some outline of the principle by which the election is guided."

Alas! The list has not come out. Why? What says the published report of an extraordinary meeting of the College on May the 29th (remembering that the outside world knows nothing except what the College allows to be published!)

"The next business was the election of new Fellows. Considerable dissatisfaction, however, was evinced by the majority of those present with the list of names submitted by the Council. Dr. Andrew moved, and Dr. Sieveking seconded a motion, referring the list back to the Council for reconsideration, with full power either to omit names, or to insert fresh ones, with the proviso, that the total number should not exceed twelve. An animated discussion followed, but finally this motion was carried by a large majority."

Having flaunted their indifference to outside opinion, the Council have at last taken action so flagrant in the matter of their selection, that the Fellows "by a large majority" have rejected their list. Instead of mending their ways, they have outraged the bulk of the Fellows, until the latter have practically turned round upon, and censured, their rulers. What motives these said rulers can have in degrading the College and its Fellowship in public opinion, it is not easy to see. It is some time ago since a leading medical journal announced that it had abandoned all hope of amendment on the part of the Council of the College; a pretty stiff expression of opinion! Instead of "amendment" they have gone on their evil path until the body of Fellows have pulled them up by rejecting their list of men presented as suitable for the Fellowship. No wonder our profession holds that position, sketched out so vividly by the author of the pamphlet, "The Political Powerlessness of the Medical Profession"! What

respect can the world have for a profession, whose ruling powers—both at the College of Physicians, and the College of Surgeons—are acting with a self-willed caprice, that could only call up a smile of derision, or the sneer of the scoffer; if it were not for the harm they are doing by the natural affection one feeble man manifests for another, until the proportion of mediocrity becomes (or would become) overwhelming! What intellectual, or moral blight is it which falls upon medical men; so soon as they enter the ruling bodies of the tainted corporations? Men of integrity in their private life, of good professional reputation, seem to become utterly transformed when they get upon the Council of the College: they seem, indeed, "to put on corruption." However, at last the good sense of a long suffering profession has shown itself, and there seems a prospect of its casting off a yoke which has galled it—a thralldom which has been no credit to it. Such a positive step by "a large majority" of the Fellows ought to lead to some results at of the College of Physicians. If outside opinion is impotent to influence the rulers of the College, surely this evidence of internal dissatisfaction can not be sterile of result. It ought to convince the erring oligarchy of the folly of which they have been guilty—of the blunder which they have perpetrated—of the injury which they are inflicting on a venerable, if not positively infirm corporation; whose natural guardians they assume to be. *Quis custodiet custodes?* Yes, indeed! A college which prides itself on the fact that it guarantees the conduct of its Members and Fellows, cannot do better than set to work to construct some means of guaranteeing the conduct of its Council.

Yours, &c.,

M.D.

THE INCREASE OF INSANITY.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—I should be sorry to deprive Dr. Wallace of the satisfaction he evidently feels in having, as he says in yesterday's *Medical Press*, so sharply criticised my paper on "The Increase of Insanity, &c.," and so vigorously tested my mental capacity as well as the data from which I deduced my conclusions. Personalities are proverbially the resource of those who have a weak cause. Therefore, I leave them to Dr. Wallace; but, with regard to the data on which I based my statements, I may observe that, beyond the expression of his own incredulity, Dr. Wallace has not even attempted to disprove in any way the evidence I collected from official and other statistical documents to prove the progressive and rapid increase of insanity of late years in these countries. And hence, as Dr. Wallace's individual opinions, valuable as they may be, cannot altogether outweigh established facts and figures I must still adhere to my published statements, however "startling" he may find them.

Secondly, the causes which I assigned for this increase of mental disorders makes Dr. Wallace fear that I do not come out well as an accurate thinker or reasoner. Now, may I venture to ask in which of the following causes referred to in my paper does Dr. Wallace find such evidence of my mental incapacity? These causes, according to my views, are moral as well as physical, and both largely arise from the changed conditions of society with the past couple of decades, the race of life being now too generally run at a pace destructive alike of mental and bodily health. Amongst the many circumstances which thus conduce to the increase of insanity are the prevailing tendency to alcoholism in all classes. Secondly, the crime of luxury and sensuality too generally characteristic of the youth of the present day. Thirdly, the forced system of education, by which the mental powers are over-strained and prematurely exhausted in the effort to acquire that superficial smattering of universal knowledge now generally deemed necessary. Fourthly, the misdirected tendencies of modern female education, and the neglect of suitable occupation for women in after-life. And fifthly, the growing frequency of those utero-ovarian complaints which have come into such prominence of late years, and which are productive of reflex cerebro-nervous disorders—must all be recognised as powerful factors in the increase of insanity so observable amongst women at the present time. Dr. Wallace, however, maintains that, "except the first of these evils, it is manifest that a very fractional proportion of the population are affected by such influences." I cannot

agree with him in this; competition for life is now almost equally great in every class, and the efforts to attain a superior station, or to ensure success in life, have led to forced education in every rank. My experience has not been confined to Ireland, as Dr. Wallace seems to think. But even in Ireland I have for some years had daily occasion, in hospitals and private practice, to trace cerebral disease to premature stimulation of the mental powers and brain over-work in the national schools, where the poor are now absurdly over-educated, as well as in collegiate institutions of a higher class. Nor am I aware that the utero-ovarian disorders to which I have assigned a prominent place in the modern etiology of insanity in women are confined to any special class or rank in society.

On Dr. Wallace's theory, "that the source of any real increase in insanity is to be sought for mainly in the condition of the lapsed masses in cities," I am unable to express any opinion, as my "mental capacity" is too limited to enable me to understand its meaning. I am glad, however, that Dr. Wallace at least endorses the practical conclusions which I endeavoured to establish, namely, that the treatment of the insane should be confined to those who have some actual knowledge of the physical diseases which may produce reflex cerebro-nervous disorders; and secondly, that some change is required in the system and laws under which patients are now admitted into lunatic asylums.

I am, &c.,

THOMAS MORE MADDEN.

55 Merrion Square, Dublin.
June 5th, 1884.

WHAT IS MEDICAL ADVERTISING?

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—A custom obtains among members of the theatrical profession which possesses so many obvious advantages as a means of engaging public attention to those who adopt it, that it is not surprising to find medical men also resorting to it for advertising purposes. I refer to the exhibition of cartes-de-visite and other portraits of physicians and surgeons in the shop-windows of booksellers and publishers, not only in London, but in the principal provincial towns also. As I walk along Oxford Street, Regent Street, the Strand, and elsewhere, I am able to enjoy unlimited opportunities of studying the faces and expressions of innumerable professors of the healing art; and in many cases, too, along with this privilege, I may, by an odd coincidence, distinguish the "special practice" of the photographer's original by reason of the close proximity of the picture to the last work written by him it depicts. Can you tell me for whose benefit these photographs are thus exposed to popular admiration? Surely not for the profession, for its members, if desirous of gazing on the revered features of leading practitioners, can take other means of doing so than the uncomfortable method of standing open-mouthed before a window in a crowded thoroughfare. If the system is not a form of advertisement, why is it that special requests are sometimes made to exhibitors of such things to include in their collection the photographs of particular practitioners—and made, too, by the practitioners themselves? Educationally, the plan has, no doubt, many advantages; it teaches the public to recognise particular individuals, and to associate them with the cure of particular diseases; and when the daily papers herald forth that Dr. So-and-so is in constant attendance on an illustrious patient, a personal interest attaches to the announcement in the mind of every chance inspector of the counterfeit presentment of the attendant in question. To the latter the philanthropic wish to inform the public mind as to his own appearance thus brings its due reward; and this it must be that stimulates the profitable benevolence of so many of our "leading stars." There is much encouragement in this reflection, and for younger and struggling men it opens up a field of usefulness and profit of which they may be trusted, as is occasionally proved from the presence of unknown faces, duly subscribed, among the collections referred to, to avail themselves as far as possible.

Yours faithfully,

AES,

Notices to Correspondents.

PRACTICAL PHARMACY IN THE EXAMINATIONS OF THE ROYAL COLLEGE OF SURGEONS.

To the Editor of the MEDICAL PRESS AND CIRCULAR.

SIR,—In the next issue of your valuable paper would you be kind enough to answer the following questions: 1. What book on elementary pharmacy would you recommend me to study? 2. Could you give me an idea of the kind of questions likely to be asked on elementary pharmacy at the first examination in medicine in the College of Surgeons, Ireland?

Yours, &c.,

CORKONIAN.

[The desiderata of this examination may be briefly given as follows: No. 1. Weights and Measures.—The student should endeavour to learn the metric system, but an acquaintance with the British system of medical weights and measures, and their popular equivalents of teaspoonful, &c., is indispensable. This is no needless request; for example: One gentleman on being shown some brass weights positively declared he "did not know what that medicine was or its dose," and an utter ignorance of simple weights and measures is very common, even in advanced pupils. No. 2. To be able to read the pages of the "British Pharmacopoeia," and understand the meaning of "infusum," "tinctura," "decoctum;" and when we state that candidates were unable to explain the words "aede," "mel," radix, folia, &c., it will be seen the amount of knowledge required is not unreasonable from young lads who are supposed to have recently passed an examination in Latin. No. 3. To translate simple Latin prescriptions into English, and explain the ordinary words, symbols, &c., and to understand the usual contractions, such as misce, cras, mane, pr., stet., s.l., ft. haust., &c. No. 4. To know something about the more usual operations of pharmacy and pharmaceutical chemistry. For illustration: One ingenious gentleman who had somehow learned how to fold a filter paper, when requested to place it in the funnel, ingeniously tried to balance it on the orifice of its spout; another could not form the slightest idea what a funnel might be used for. It is far from uncommon to find a thermometer in either its simple or self-registering form above comprehension. Ordinary matters of evaporation, or the use of a spirit lamp, unknown; an evaporating capsule grossly termed a mortar, and all idea of specific gravity considered unworthy of study. In the examination itself, as there is neither time nor opportunity for practical work, the candidate's knowledge is tested by questions, and the use of prescriptions and instruments, and an appeal made to the pages of the "Pharmacopoeia" itself. No text-book is recommended for obvious reasons, there are several that may be consulted, but any individual with sufficient intelligence to pursue our profession hereafter would acquire all the requisite knowledge in a dispensary or pharmacy far easier than by reading, just as bandaging is best learned by practicing it on the human body, so will practical pharmacy be best acquired by spending a few hours behind a pharmacist's compounding department, or in the dispensary of an hospital, and the knowledge thus acquired will go a considerable way to smooth the difficulties in future surgical and medical studies. The object of the examination is to secure such an amount of elementary information before entering on his strictly practical professional studies that it may be turned to the best account, not only for his future examinations, but for the practice of his profession in civil, naval, or military life hereafter. —ED.]

DR. CULLMORE.—We hope to find space for your paper in our next, or at latest the following number.

MEDICAL "ATTENDANT" OR MEDICAL "ADVISER."

To the Editor of the MEDICAL PRESS AND CIRCULAR.

SIR,—I think the profession as a rule do not like the word attendant when following coffins of public funerals. Webster's Dictionary defines "attendant" as one that attends or "waits on," meaning a servant really. Members of our profession are advisers, in the same light as spiritual advisers, legal advisers; therefore, why not use the more dignified and more appropriate term of "medical adviser?" At the funeral obsequies of Sir Bartle Frere, Sir So-and-so are named medical attendants. The term ought to be altered. Sir Bartle Frere was a very able man, of Indian experience. Who gave India to England? Why, a member of the medical profession. A noble-minded surgeon in the pristine days of the East India Trading Company was requested by the Great Mogul at Calcutta to prescribe for his daughter. He did, and cured her. The Eastern potentate bowed to the talent of a profession that carries more influence than any other in the East, and asked the Company's surgeon his fee. This noble-minded man requested that his Company should be allowed a possession of a piece of ground at Calcutta to trade from. It was granted, and from that request India became our possession! Are we servants? No.

Yours, &c.,

ANGLO-INDIAN PHYSICIAN.

AUSTRALIA.—A correspondent asks whether Australia "is a good field for practice." The colony is a trifle larger than the continent of Europe, and presents every conceivable field for practice. We know of no sort of practitioner, if not blind, or stone deaf, or a drunkard, who could not find a place to suit him in the colony. Not knowing anything about our correspondent's qualities, physical, mental, or professional, we can give him no better answer.

NITRO-GLYCERINE.

IN our last issue space was accorded to correspondence on this subject, in which a small but important typographical error appeared, which we desire to correct, namely, the substitution of r for s in glonorin; this word should read "glonoin" (nitro-glycerine). It may be as well to mention, for the information of our readers, that this substance, even when prepared for medicinal purposes, if not perfectly pure, is liable to explode spontaneously, but in fatty or oily solution it is absolutely safe. Two minutes after taking a dose, the pulse becomes accelerated, arteries relaxed, and a throbbing headache is produced, which lasts according to the strength of the dose. Its use is principally indicated in angina pectoris, persistent neuralgia, and sea-sickness, its action being like nitrite of amyl, than which its effects are more lasting.

MR. J. LLOYD (Bethesda).—We shall be glad of notes of the case of "Sporadic Cretinism" under your care; they would doubtless be interesting to many readers.

The Societies, College Lectures, &c.

WEDNESDAY, JUNE 11TH.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—At 4 p.m., Sir Henry Thompson. On Some Important Changes in connexion with the Surgery of the Urinary Organs.

EPIDEMIOLOGICAL SOCIETY OF LONDON.—At 8 p.m., Dr. H. Franklin Parsons. Some Observations on the Etiology of Diphtheria.—Dr. John Wortabet. Epidemiological Notes during the Autumn of 1883 in Beyrout, Syria. Office-bearers for the ensuing year will be nominated.

ROYAL MICROSCOPICAL SOCIETY.—At 8 p.m., Dr. J. Anthony, On the Camera Lucida.—Mr. G. Dowdswell, (1) On Some Phenomena of the Red Blood-Corpuscles of Vertebrates, with reference to the occurrence of Bacteria normally in Living Animals; (2) On the Constancy of Specific Morphological Characters in the Bacteria.—Mr. C. D. Ahrens, On a New Polarising Prism.

ON SOME

IMPORTANT POINTS IN CONNEXION WITH THE SURGERY OF THE URINARY ORGANS.

Delivered at the Royal College of Surgeons,

By SIR HENRY THOMPSON, F.R.C.S.,

Surgeon Extraordinary to his Majesty the King of the Belgians, Professor of Surgery and Pathology to the Royal College of Surgeons of England, Consulting Surgeon to University College Hospital, Emeritus Professor of Clinical Surgery, &c.

LECTURE I.

Introductory.—The Treatment of Stricture of the Urethra by Internal Urethrotomy.

MR. PRESIDENT AND GENTLEMEN,—It will be my object in this course of lectures to consider certain grave forms of disease which affect the urinary passages, for the purpose of examining the nature of these affections, and to discuss the best method of treating them. I cannot enter on this important task without expressing my deep sense of the very high honour which the Council of the Royal College of Surgeons confers in assigning to me the position which I occupy to-day. Equally also am I conscious of a profound feeling of responsibility in accepting the invitation to present in this place an exposition of opinion relating to some of the most important themes of thought and activity which have occupied the intellects and the energies of surgeons from the earliest time to the present day. There are two considerations which I am bound to submit to you, since they are those which have influenced my own mind as in some degree a justification for my presence here, and which sustain me in view of the task imposed. The first is that a period of at least twenty-five years of very active engagement in the practical observation and treatment of the diseases in question has furnished an experience which, I believe, is almost without a parallel at the present day. The second consideration is, that it has been my habit from the very first carefully to record at the time in writing every case I have met with, and to see that such

notes are systematically arranged and preserved, so that they can be produced and referred to whenever required. It is my sincere desire now to offer to my professional brethren a faithful epitome of these facts so far as they relate to the subjects to be treated. A few words more I venture to utter regarding myself, and I do so only for the purpose of explaining how it is that the experience referred to has been so ample in respect of these particular diseases. I do so with the less difficulty because the explanation is found almost solely in connection with our Royal College. I just now spoke of twenty-five years of active surgical practice, but thirty-three years have elapsed since the Council of the College offered for competition, in 1851, as the subject of a Jacksonian prize, the "Pathology and Treatment of Stricture of the Urethra," many questions concerning which were at that time warmly discussed by the profession both at home and abroad. The time happened to coincide with my entry on professional life, after an active house-surgery at my hospital and elsewhere; and such a proposal offered the very occupation wanted by one whose time was then unoccupied, and who desired nothing so much as a defined object at which to work seriously and laboriously. It was the accident of obtaining that award, and not long after of another Jacksonian prize for an essay on the Prostate, in 1859, which determined the nature of a career which I had never dreamed of thus shaping for myself. I claim therefore the honour of being in an especial sense—and it is a legitimate source of pride, I trust, within these walls to do so—a son of our noble College; and after the third of a century continuously devoted to studies thus initiated, I am here to report myself at the paternal hearth to-day, happily finding one of my earliest teachers and College friends worthily occupying the presidential chair. The seeds were sown, Sir, by your predecessors here, and they selected the variety which was distinct; the gathered harvest could only correspond thereto, and, such as it is, I desire, with your permission, to garner it here.

[The lecturer then gave a brief but carefully considered historical sketch of the treatment of stricture of the urethra in England and abroad, during the present century, with a view of "tracing the formation of opinion respecting it,

and of pointing out a growing concurrence in opinion among practised surgeons, that in dealing with stricture by operation, free incision of all the opposing structures must be adopted, or the result will be temporary only, and disappointing.]

I have just alluded to Professor Syme's early enunciation of this principle, which he decided for himself could only be effectively realised in practice by an operation performed in the perineum; a proceeding which met with great opposition here, and was the occasion of a very acrimonious discussion. A cardinal defect in his method is now at this distance of time apparent. Recognising the truth I have been insisting upon, that the division of the stricture must be complete, he limited himself to the division of one stricture only; rarely being able to reach or deal with two from the perineal wound, if, indeed, he cared to recognise the existence of multiple stricture; or at all events doing so, he believed in the disappearance of other or minor contractions, after the principal stricture had been freely divided. There is no warrant, however, for any such belief; it will not suffice for the purpose of affording substantial relief to a patient, whose urethra is narrowed by stricture in two or three distinct situations, to divide, however freely, only the chief of these and leave the rest untouched. So far from a secondary narrowing disappearing after what has been termed "the master stricture" has been cut, it often happens at no distant period that the points formerly slightly affected seem to assert themselves more obstinately than before. I cannot, therefore, insist too strongly on the value of an axiom, which I will venture thus tersely to formulate: "If you cut at all, cut all;"—that is, all the points in the urethra at which the presence of obstructing deposit is to be demonstrated, and all the obstructing tissue at each point. Such is the unhesitating conviction which a long and large experience of internal urethrotomy has forced upon me. In the year 1854 I published the Jacksonian essay referred to, and after much personal intercourse and study with Professor Syme, I adopted his view in relation to the permeability of stricture, a circumstance which I now regard as one of the most valuable of the many important lessons I learned from that most able, fearless, and honest man. I have in the course of my life met with three instances in which after much careful manipulation I have been unable to pass an instrument fairly into the bladder, and in these three instances only have I performed perineal section for the relief of stricture, without a guide previously passed. Between 1852 and 1855 I operated by Syme's method of external urethrotomy upon a grooved staff, nine times only, thenceforth exchanging it for internal urethrotomy which I have practised systematically ever since; at first on the very worst forms of the disease only, and gradually as the result of increased confidence in it, and satisfaction with the results, much more frequently than at first. And now and then, but very rarely, for example, when large abscess and perineal fistula affect the perineum, the division on a grooved staff has still been resorted to. These remarks on this important subject lead me now to present briefly an epitome of what my experience has led me to regard as the safest and most efficient mode of treating a confirmed example of organic stricture of the urethra.

I think it will be agreed by most experienced surgeons, that on first verifying the presence of a urethral narrowing, the history of which is recent, as a rule nothing need be done beyond gradually restoring the calibre of the canal to its normal state or thereabouts by means of flexible bougies. The well-known form styled "olive" can scarcely be improved, and if it is desired to carry the process of dilatation as far as possible, the well-polished tapering silver or silver-plated steel dilators are very efficient, and at the same time unobnoxious to the passage. Modifications of the flexible bougie are, however, now so numerous, in regard to form, material, and even also to their internal contents, that each surgeon will doubtless employ most advantageously that which best accords

with his own views and with his own manner of manipulating. There are of course congenital organic as well as acquired narrowings of the external meatus, and near to it, which will not dilate, and which a simple incision suffices to divide. Strictures also affecting the canal within three or four inches of the orifice do not benefit much or for any prolonged period by dilatation. But when in the ordinary case of recent stricture the canal has been restored to a full calibre by dilatation, it may be often maintained so by an occasional regular use of the bougie by the patient himself for several, sometimes for many years. In after-life, however, as all the tissues become more rigid, those which form the stricture also dilate less readily, and a smaller instrument than formerly can now only be passed. But sometimes even this sign scarcely shows itself, for which reason I think it unwise as a rule to propose an operation in the early stage of stricture, but prefer to afford a patient the chance of its being amenable for many years, if not altogether, to the very simple treatment indicated; but whenever a decided tendency to contract manifests itself, be it sooner or later, I think it is wise to resort to internal urethrotomy without delay. Were this plan always pursued we should have no perineal abscesses or fistulae, no consecutive chronic cystitis, with organic changes in the bladder, ureters, and kidneys as a result. To advise the delay of an operation until symptoms indicate that such complications are appearing involves complicity in a course which irretrievably damages the patient's life. Hence I have no hesitation now in advising internal urethrotomy whenever organic stricture, single or multiple, near or distant from the meatus, shows signs of not yielding readily to dilatation. No delay is in these circumstances of any value as regards the stricture itself.

When cases are first met with in a more advanced stage, when the use of dilating instruments is liable to be followed by temporary retention of urine or by rigors, then very little question can arise as to the propriety of operating. It is very rarely too late to incur any risk there may be in doing so; and the persistence of the phenomena must, if not checked, undermine the constitution of those who are the subjects of them. In relation to those cases in which rigors almost always occur after the passing of a bougie, I know nothing so admirable as the results of urethrotomy, since, if completely performed, the operation itself is in these very cases rarely followed by such an occurrence. I am convinced, therefore, of the necessity of ensuring complete division of all the obstructing tissue, not only in relation to future results, but to the present well-doing of the patient, and thus have an additional support for the value of my maxim, "If you cut at all, cut all."

This brings me to a very important subject, How are we best to ascertain before undertaking to divide the morbid tissues constituting stricture, what are their extent and situation? In other words, What is necessary, for our purpose, to be done in order to diagnose the physical condition of the urethra? It may first of all be remarked that in a simple and recent case of strictured urethra, and therefore for a large proportion of all the cases of stricture, a very simple proceeding suffices to ascertain where and to what extent the canal has been morbidly narrowed; and as all instrumental interference with the urethra, however delicately effected, is apt to provoke irritation, which in a few persons is serious; we are not warranted in introducing large or complicated mechanical contrivances for the purposes of diagnosis—at all events in recent cases. It suffices for the purpose to introduce a full-sized bougie, by which I mean one which will pass in a healthy urethra without stretching it, merely separating its walls to about the same extent as the flow of a full quantity of urine will do when it passes naturally. Such a stream in most persons equals a volume, perhaps, of 10, 11, or 12 of the English scale. If such an instrument fails to pass, we diminish the size until one is found which does pass, after which dilatations may mostly be speedily and efficiently made, and nothing more may be necessary. If more specific information is

desired in an exceptional case, a series of solid bulbous ended instruments, of which the stem is slender, and each bulb follows the sizes of the catheter scale employed, will supply accurately the data required, and on the easiest terms possible to be obtained. Such a series I have used for thirty years, and no other, except for trial; and I have never seen any plan equal to this for simplicity, efficiency, and for effecting the object without inducing irritation; they are better also than flexible instruments of the same form, which are less easily used and far less accurate in the indications they afford.

Suppose, then, the case of a patient for whom it is decided to perform internal urethrotomy. The external meatus is first examined, and it is often found to be contracted; a bulb, say No. 11 or No. 12 in size, passes tightly through it, and stops perhaps at an inch or more from the orifice; after the use of three or four smaller sizes, a No. 9 passes, and meets a check at five inches; and here, after other trials, a No. 2 or No. 3 goes on into the bladder. On withdrawing the bulbous instrument, the situation of the contracted parts is again verified by the check which the bulb receives in passing them in its progress outwards. It is clear, therefore, in such a case that there are at least two chief points requiring incision, besides the orifice. This is all that need be ascertained before the patient is insensible for operation, when the examination may be repeated if the surgeon desires to do so with more minuteness before incising.

Now, at this point it is necessary to consider some preliminary questions of importance—namely, What is the principle on which an intra-urethral incision which is out of sight ought to be made, and what is the best instrument to accomplish the purpose? Is the division of tissue to be complete, and to be made solely according to the judgment of the operator; or is it to be made by a machine, the action of which is not necessarily to divide all opposing tissue, but simple to do so sufficiently to permit the introduction of a fair-sized catheter through the urethra, when the cutting instrument is withdrawn? For example, we may introduce a small-grooved staff along the urethra into the bladder, and then slide along the directing groove a blade more or less protected, so as to divide such tissues as lie within range of its point or edge and no more. But this I contend, is not an efficient mode of dealing with urethral obstruction, if its complete division is the object to be attained. Complete division, indeed, is rarely thus accomplished; much of the diseased tissue usually escapes the blade; the result is uncertain and is far less perfect than that which follows a section made by a knife directed by the will of the surgeon against the resistance encountered at the time and previously ascertained by exploration. I suppose that a keen blade of appropriate form and completely under the control of his hand would be always employed by a surgeon, for use in any other part of the body than the urethra, when he desires to make an incision, the limits of which are to be carefully defined. For my own part, I can see no reason why that spot alone should be exempted from the action of this principle. Take the fibres which confine a hernia, for example; here the finger and the blade act in perfect harmony, the section depending entirely on the delicate perceptions of the former, which determine the surgeon's judgment during every moment of the cutting act. The section in tenotomy is, perhaps, a still more apposite illustration of the necessity that exists for an intelligently made division of every fibre which opposes the return of the limb to its natural position. A like control should govern the act of dividing those bonds which encompass the urethra, and form the stricture. No mode of section is half so certain, so safe, and so satisfactory as that of drawing through them from within outwards a little blade attached firmly to a long slender handle, a proceeding completely under the control of the surgeon's hand. I know that this is not the generally accepted mode of operating either here or elsewhere. It is precisely for that reason, cherishing as I do strong convictions as to the superiority of the method, that I have

determined to make its advocacy the main theme for our consideration to-day. I am told, both here and abroad, that the cutting blade sliding in a groove of which Maisonneuve's instrument is the type, is so simple and safe a proceeding that any man, however unpractised, may perform it. Is that a reason in its favour? The same doctrine was very lately taught in relation to the method of splitting strictures by means of two diverging rods, at one time so much in vogue; now so completely and so properly neglected, but always so easy of performance. Are we to accept an unsatisfactory proceeding because of its universal applicability, and thus be content to establish an imperfect standard for the sake of bringing it within the reach of incompetent operators? Between the two systems now under consideration there is this difference—one is the product of a machine, and the other is the handicraft of an artist. And the same distinction which is so obvious in regard to innumerable forms of human activity, between the uniform and common-place results of machinery and the finished achievements of the intelligent painstaking artist, marks the character of the two modes of operating now in question. And let me remark that the practice of operative surgery becomes a sorry occupation, if it be not indeed an art, and a very fine art, too. So far as it becomes a mere matter of mechanical contrivance, it ceases to be worthy of the devotion of a man of parts. A cultivated hand is the most cunning and effective source of power; and the simpler the instrument employed the greater is the influence of that hand and of the intelligence which guides and permeates it.

In operating for stricture I have, during the last twenty-five years, used only a little blade with a long handle, and have always commenced by placing that blade on the further side of the stricture, and made the incision in a direction towards me—that is, from behind forwards, cutting just so much in length and in depth as the obstruction perceived at the moment appears to demand. Now, in order to place a small blade beyond or on the bladder side of a stricture, a certain amount of space in the urethra is required. In the case above supposed, in which the deeper stricture of the two admits only a bougie No. 2 in size, there is not room for a sufficiently strong instrument containing the blade to be so placed. But a little dilatation will enable it to pass; the calibre of No. 5, English, suffices for our purpose. Hence in such a case I simply tie in a gum catheter (No. 1 is ample for the purpose), and retain it there two or at most four days. By that time, without changing the catheter for a larger one, or only once, the necessary enlargement of calibre is accomplished. The urethrotome which I employ is made on the principle of one used many years ago by Civiale, but in a manner differing widely from his, already described, and modified in one or two points by myself. The bulbous end has a mean diameter of No. 5, the stem is about two and a half or three inches. The patient being under the influence of an anæsthetic, the little catheter which has been tied in is withdrawn, and the urethrotome is first introduced as far as to the deep-seated stricture, through which the terminal bulb is then insinuated. It must now be passed fully half or three-quarters of an inch further in—that is, beyond the stricture, and the blade being exposed in a direction towards the floor, is pressed firmly thereon and drawn forward, until all resistance, sometimes considerable, is completely overcome. A touch on the button near the handle sheathes the blade, and the outward movement proceeds until the site of the second stricture is reached, when another incision is made in the same manner as before. The urethrotome is then withdrawn, and the meatus freely divided by a scalpel or a short urethrotome. I next take a blunt metal bougie or dilator No. 15 or No. 16, English size, and ascertain if it will pass without obstruction into the bladder. It generally does so at once; if, however, its progress is arrested at any point, the situation of this is carefully noted, when I withdraw the dilator, reintroduce the

original urethrotome, and divide the opposing tissue. But this, as I before said, is seldom necessary. I may add that I am very rarely satisfied with anything less than the free and easy passage after the operation of a metallic sound, No. 16 in size, and in some cases No. 17 or even No. 18 will pass. A gum elastic catheter, No. 12 or No. 13, is then tied in, and should remain always forty-eight hours, with an extra twenty-four or forty-eight hours if the incisions have been deeper than usual or if hæmorrhage is free or continuous, the latter being a very exceptional occurrence. It is sometimes objected that if a small instrument can be easily passed through the stricture, and if this may be easily dilated so as to admit a urethrotome as large as No. 5, why should any cutting operation be performed? The reply need only be brief; the object of division is to remedy the tendency to recontract, which certain strictures exhibit, and which almost all do when they have continued several years. In other words, it is marked contractility in a stricture, and not mere narrowness, which renders operation by incision desirable.

An important inquiry remains, What are the results of internal urethrotomy in relation to the reappearance of stricture? Does the operation free the subject of it from that liability to return which constitutes the very serious character of the disease when treated only by dilatation? The reply to this question cannot be a simple and categorical one; it must be made with limitations. I may remark, first, that it may be taken for granted that no mode of urethrotomy which fails to ensure complete division of the obstructing tissues has a chance of affording permanent immunity from the complaint. Whatever the mode of operating, if incomplete division only is effected, the patient will find his urethra narrowing after a more or less prolonged interval of time. What happens, then, in those cases in which, as far as the operator can judge, he has effected a complete division? Well, I am free to confess that it is not possible to promise immunity from return. We may render the period of return remote, we may produce a good calibre easily maintained by occasional regular dilatation, a procedure which before the operation was not only ineffective, but painful and irritating; we may place a patient in a condition of health and comfort for several years, meantime saving his bladder, ureters, and kidney from the slowly but surely occurring grave changes which threaten his existence. Now and then, but rarely, I have met with a case in which the patient's troubles have never reappeared. I am certain we cannot reckon on this result as a rule, and I mistrust claims to the contrary, as due to error of judgment, or want of information; or as prematurely made—i.e., without waiting sufficiently long to observe remote results. In enunciating this opinion, I have no hesitation whatever. But herein I have stated the worst in regard of the patient's prospects; and have shown you the reverse of the medal. Thus, supposing after a few years the patient finds himself unable through appearance of contraction to pass a bougie of adequate size, division can again be resorted to. It is not a dangerous proceeding, necessarily occasioning hesitation on the part of the patient, when his condition demands relief. Just as in calculous cases, a second, a third, or even a fourth stone, can be, and often is, safely removed by lithotomy when, after the lapse of time, fresh products are formed; thus also may a stricture be dealt with by this operation, a second or a third time if necessary. By the prompt resort to the remedy, should it be again required, the disease may be confined to the canal, and the real gravamen of the malady, the implication of vital organs, certain to result after long-continued ineffective dilatation, is altogether avoided.

I have performed this operation now for between 300 and 400 patients. Some of my earliest cases were, from want of sufficient confidence and experience, less completely and freely cut than those on whom I have operated of late years; and a few of the early patients have been recut. I have not regretted such advice in a single

instance; for the advantage to them has been undoubted. The risk of the operation is very small. Estimating the number of patients on whom I have performed it as 340, which is within five more or less, the deaths have been six, or not two per cent. These were due to pyæmia in three; to embolism in one; to extravasation and exhaustion in two; one of the latter was a case in hospital almost thirty years ago, among my earliest, and he was unfit for any operation.

The sum of my experience is the expression of a strong conviction that internal urethrotomy completely performed should be resorted to as the best and safest treatment of stricture, as soon as the easy use of the bougie fails to maintain the urethra patent, or to allay signs of irritation in the bladder arising from obstructed urethra. It is the best means not only for relieving urethral obstruction and its painful symptoms, but for ensuring the future sound condition of the organs which lie behind it.

CONSUMPTION VIEWED IN RELATION TO EVOLUTION AND MOLECULAR ENERGY.

By WILLIAM H. PEARSE, M.D.,

Senior Physician to the Plymouth Public Dispensary.

(Concluded from page 536.)

Teeth.—A marked correlation exists between the upper incisor teeth and phthisis. In Nature, no one can predicate which simple fact or phenomena, shall furnish the "instance of alliance" (a) which shall open to our view the connection between phenomena, seemingly remote from each other: hence it is just, that we study the whole breadth of associated correlations.

Two hundred and thirty-two of the pre-phthical and phthical showed preceding and associated decay of the upper incisors: of these, seventy-four had actual phthisis. The decay of the teeth usually precedes that of the lung. About forty cases had phthisis, but with no affection of the upper incisors; about sixteen had early phthisis and sound upper incisors; about forty-one delicately-typed patients had sound upper incisors. Of course, there are vast numbers, whose upper incisors are decayed, but who do not pass into phthisis; but from constant observation, far more than from any approximative statistics, I am sure that a very marked correlation exists between the upper incisors and phthisis. I feel sure also, that a correlation exists between the upper lateral incisors and phthisis; very small upper lateral incisors indicate a future tendency to phthisis; but it may not always be in that individual, but in a brother or sister, &c. Seventy-six cases of the "delicate" and phthical, had small lateral upper incisors; in about ten they were congenitally absent; one had exchange of place (like) between the middle and lateral incisors.

It is rare for the under incisors to show decay; one delicate girl had perfect upper incisors, and decayed canine. I often see both the upper and lower canine decayed, but in nothing like the numbers which have disease of the upper incisors.

It is not meant that any "specific" relation exists between the upper incisors and phthisis, but that the natural declination, at certain ages, into phthisis, is much related to and is part of the same "form," as is the early declination of the teeth. The popular and partial theories on the decay of the teeth, e.g., that it is due to the development of micro-germs, to undue acidity, &c., of the salivary secretions, to "derangements of the digestion" (whatever that may mean), do not give any

(a) Bacon says, "Novum Organum," Part 2, Aphorism xxxv: "Instances of alliance show that operations and effects attributed to some one heterogeneous nature as peculiar to it, may belong also to other heterogeneous natures; so that this supposed heterogeneity is proved to be not real or essential, but only a modification of a common nature. They are, therefore, of most excellent use in raising and elevating the understanding from specific difference to *genera*, and in dispelling phantoms and false images of things, which in concrete substances come before us in disguise."

real explanation of the phenomena. We have seen that the decay is mainly associated with certain nerve distribution, that its being seen so much in the upper incisors, points to alliances in the phenomena, shown in the deeper involvements of the upper maxillary and nasal bones. We have to seek at the origin of the nerve supply, in the cerebro-spinal axis, for an approximative explanation and generalisation. But in this study, the question of diet cannot be excluded. Species and types of animals (including man) are not fixed, but absolutely correlate with environment, including diet. One cannot but be struck with the fact that natives of India, who eat a whole-grain diet, both of rice and approximatively of wheat, do not lose their teeth so much, or so often pass into phthisis as we do; but they live an out-of-door life, and the climate differs so vastly. When staying in Demerara, I was often told that field negroes do not die of phthisis, but that the civilised negro does, that is to say, the clerks, schoolmasters, &c. It has always appeared to me that a most valuable contribution toward the etiology of phthisis could be made by a careful and full comparison of these two classes of negroes. Nor is it unreasonable in this country, to look at faults of our food, as paramount even, in determining the nerve "energy" of those spinal centres, which render possible the unhealthy growth of upper incisors and lung tissues. I have notes of twenty-three cases of phthisis, in which the right lung was diseased in eleven, the left in eight, and both lungs in four cases, in all of which the upper incisors were sound.

Nails.—Club nails are often seen in other disease within the thorax than phthisis, but far less often than in the latter. That what I desire to remark on is, that in many of those who eventually pass into phthisis, there exist long preceding types and structural sympathies in the nails, thus pointing out to us the deep involvements of the disease. I have noted sixty of the pre-phthisical and phthisical as having fine almond-shaped nails; besides these, some have nails of great length and extreme thinness; a smaller proportion have the largish rounded nails. I often notice that the index nails alone, are unsymmetrical and slightly clubbed. In a very considerable proportion, the nails are unduly large. It is, I believe, a sign of probable future phthisis, where the nails have transverse ridges, or where they are unusually thin and brittle. A very striking phenomena is, that of the nails being hollowed or concave; the thumb, index, middle, and ring finger nails show this most. I have a number of cases recorded, in which this variation of the nails showed in families in which phthisis had much prevailed; it is frequently atavistic to phthisis of the lungs. In going around cancer wards, one is struck by the masculine physique of the sufferers, their disease seeming like a natural exuberance of cell evolution at certain ages, just as warts are in the young; but in phthisical patients, such phenomena as we are considering in the nails, besides the long series of other associated phenomena, seem to show a deficient amount of the evolutionary "energy" of growth. The different members of a family, in successive and the same generations, are units of one series; all the varied pre-phthisical and phthisical symptoms and signs are "contained varieties;" they are all related to a common "form," and correlated. We may deeply seek to know how, e.g., Mrs. C., æt. 35, who is suffering from insidious pleurisy, and probably early phthisis, as its cause, and whose children and cousins are phthisical, how it is, in the profounder anatomical correlations and vital energy, that her thumb, index, middle, and ring finger nails are deeply concaved.

It cannot be in vain that we should keep constantly in view the broad biological and physiological involvements, and the great time, which belong to phthisis. We have to consider the facts of heredity and atavism; the long and varying periods, in different individuals, in which, prior to tubercular degeneration, healthy lung structure is evolved; to seek to differentiate the groups of cases which pass earlier or later into phthisis, in correlation with

deviations of anatomical structure, and with deviations of function. We have to study the order of the evolution of the changes, whether of function or structure; to observe the exceptions to the prevailing law or order, e.g., as when we find patients able to eat fats, or whose lateral incisors are large, exceptions which mark the oscillations, within their limits, of the rates of vital development.

The wide correlation of phthisis to animal type is seen, in that, whilst the convicts at Prince Town, Dartmoor, die as 2·6 per 1,000 of phthisis, the lunatics in Exminster Asylum die as 20·96 per 1,000, both, as compared with 2·47 for the general population of England and Wales. This great exemption from phthisis, of the convict-type of man, is the more remarkable, in that the prisoners in Dartmoor are at those ages during which phthisis predominates: the Registrar-General states, in reference to England and Wales, that between 20 and 25, "nearly half of all deaths are by phthisis"; between 25 and 35 phthisis "is the most fatal disease of this age"; between 35 and 45 "phthisis still predominates." (a)

We reach a point to see that phthisis has a very wide "form," that the lung phenomena are secondary or later parts of an orderly and long antecedent series. We are led to seek central nerve involvement, not only in the individual, but in part also, in heredity. We must not so much view phthisis as a disease, but as an absolutely natural phenomena, having a regular and necessitous order of evolution. Taking a group of cases of phthisis, we have to seek to differentiate the slow from the rapid cases, the aged who pass into phthisis, from the young. It is a very striking phenomena to see cases of advanced phthisis remaining, for years even, in *statu quo*, even amongst the very poor and badly fed; whilst other cases advance so rapidly; there is a graduated series between these extremes, it can only be, that the differentiation of vital "energy" must be infinitely small in degree, though all potential.

Any hypothesis, implying the "specific" nature of phthisis, can have no expansion, equal to cover the great variety and far-back-reaching correlations of phthisis. If we view phthisis as a "disease" of the lungs, cellular or bacterial, we shall utterly fail to grasp the true "form" of the phenomena.

Have we not hitherto looked too much on diseases as actual entities; have not the necessities of nosological (b) systems tended to confine our view of diseased phenomena; has not the method of the "specific," now happily discarded in other domains of Nature, in languages, philosophies, modes of matter, animal and vegetable forms, &c., &c., hindered us from seeing the true place and wide correlations of phthisis, and many other so-called diseased phenomena; have we not viewed man and his deviations, in a manner too isolated. May we not fairly extend the great hypotheses of "correlation" and "continuity" to the organic series; and thus view man and his deviations in far wider correlations with Nature, and involving a far greater time, than we have been accustomed to do. May we not fairly use the hypothesis of evolution deductively, and using the hypothesis of "continuity" deductively, seek our remedies in correlated modes of matter, aiding our path of method by the laws of Isomers.

I believe that we shall never compass the "form" of phthisis, until we go far deeper into "being," than pathological structure can show, or even than deep nerve changes can show, pathologically; we cannot rest short of a molecular vito-chemistry; function is the galvanometer, and thermo-electric-pile, of these first, immeasurably delicate changes of "mode."

I have seen a case of phthisis get well, after, and with, an

(a) *Journal of the Plymouth Institution*, 1876-77, pp. 87, 101, 102.

(b) Bacon says, "*Novum Organum*," Book 1, Aphorism lix: "For men believe that their reason governs words; but it is also true that words re-act on the understanding; and this it is that has rendered philosophy and the sciences sophistical and inactive. Yet even definitions cannot cure this evil in dealing with natural and material things; since the definitions themselves consist of words, and those words beget others: so that it is necessary to recur to individual instances, and those induce series and order."

out-door life of some months on Dartmoor; great numbers of patients in early phthisis, and indeed in advanced phthisis, came back after taking quinine, and arsenic, and muriatic acid, and say that they "feel much better," "feel quite well." I am often astonished at such statements: How do they feel better? We are compelled to go back beyond pathological structure, and to recognise that an actual "correlation" of "vital energy" has happened.

No fact is better known than that of the immense good which results to health, from what we call "change of air." Infinitely small as are the actual differences of environment involved in the change, yet the potential influence on health is immense; and it is by the extension of this method, and by the extension, through isomeric analogies, of the established good influences of such substances, as quinine, arsenic, muriatic acid, &c., when added to the body, that we shall be likely to reach the knowledge of potential co-ordinators of healthy function and growth; but our remedies must be used slowly, and in harmony with the natural rates and processes and changes, of healthy development.

On the other side, the almost hermetically-sealed plastered rooms, in which the poor are crowded year after year, and in which the wealthier classes pamper their bodies, and induce phthisis in their children, point to the absence of the full exposure to external physical existences, as the occasion of the decrease of vital energy, and for the evolution of phthisis.

These instances of the prevention of phthisis, and of its production, are actual entrances made into the domain of the correlation of the inorganic and the organic, and disease; and the history of all the sides of human knowledge in the past teaches us, that the largest general truths may at any moment open, and place before our minds, the most seemingly infinite and complex phenomena, as an orderly and easily recognised and controllable series.

Bacon says: (a) "... but be assured that the prolongation of life is a work of labour and difficulty, and consisting of a great number of remedies, and those aptly connected one with another. For let no man be so dull as to believe that a thing which has never yet been done can be done now, except by means yet unattempted."

Clinical Records.

CASE OF SUPRA-PUBIC LITHOTOMY IN A WOMAN—AN EXCEPTIONAL CASE.

By LAWSON TAIT, F.R.C.S.,

Surgeon to the Birmingham and Midland Hospital for Women; Consulting Surgeon to the West Bromwich Hospital.

J. M., *æt.* 24, was confined in September, 1881, being attended by an irregular practitioner, after a labour of about ninety hours. She came under my care in January, 1882, at the Hospital for Women, as an out-patient, and I found that the whole of the posterior wall of the bladder had been destroyed, leaving only a fragment of the trigone and the urethra. A large amount of the posterior wall of the vagina had also been destroyed. I admitted her, and by a series of plastic operations, seven in number, and consisting chiefly of bringing flaps from the posterior and lateral parts of the vagina, I managed to build up a new posterior wall for her bladder, and to fasten it to the stump of the trigone. I had to turn the remains of the cervix uteri into the bladder, and when the recovery was complete there was very little vagina, and menstruation occurred into the bladder. That viscous, however, in the course of a few months became large enough to contain nearly eight ounces of urine, and it was completely under her control as long as its contents did not exceed that amount. Her existence, therefore, became one of comparative comfort, and remained so until she had to accompany her husband, a soldier, to Ireland. She came back to me in March of this year with symptoms of stone in the bladder, and I easily found and

crushed a large stone with great, but not with complete, relief. After several soundings I found another stone (possibly a fragment of the first) in the posterior and upper part of the bladder. I could only touch it occasionally in certain positions, and I could not lay hold of it with the lithotrite, though I tried many times. I became certain, therefore, that it was lodged in a pocket made, in all probability, by the puckering of my artificial work in closing her bladder. The question came, how was I to get at it? Vaginal lithotomy was out of the question, as I must of necessity undo all my old success. Dilating the urethra I do not like, and if I did it in this case there was the possibility that even then I might fail to get at the stone in its pocket. I therefore determined to open the bladder from above. I had never performed supra-pubic lithotomy, and I had never heard of its being done in a woman. I have opened the bladder several times unwittingly in removing uterine tumours, fortunately never with any ill result. I have seen supra-pubic lithotomy performed only twice; in both cases the peritoneum was opened, and both patients died. I am not afraid of opening the peritoneum; still I was anxious to avoid doing so, and therefore I kept very close to the pubis, and an assistant pressed the fundus of the bladder up with a sound passed through the urethra. With all my precautions, I did open the peritoneum, and can easily understand how this method of removing stones from the bladder has never become a popular one. I found the stone in a pocket on the left side of the cervix, in such a position that I could not have removed it, at least, not easily, if I had passed my finger from the urethra. I closed the wound in the peritoneum very carefully, and passed a drainage tube through the urethra and out at the wound in the base of the bladder. The patient has made an excellent recovery, the supra-pubic wound is now nearly healed, and she passes water without discomfort. The stone was, as usual, a very soft phosphatic concretion, and was adherent to the wall of the sac in which it was situated.

In such a case as this the tendency to the formation of stone is very great, and in many of my bad cases of vesico-vaginal fistula I have had to do lithotripsy at intervals after I had closed the aperture. Lithotripsy in women is such a perfectly easy operation that until now no difficulty has arisen; but in this exceptional case I think I adopted the only possible course.

Birmingham.

Transactions of Societies.

ACADEMY OF MEDICINE IN IRELAND.

SURGICAL SECTION.

At a meeting of the Surgical Section, in the Royal College of Surgeons, Mr. WHEELER, President, occupied the chair.

Mr. STOKES read the minutes which were signed.

ABDOMINAL TUMOUR.

Mr. BARTON read a paper on a remarkable case of abdominal tumour. T. A., *æt.* 25, an engine fitter, was admitted into the Adelaide Hospital on 27th November last suffering from a constant pain in the abdomen and painful and constant micturition. On examination, a tumour was found in the left inguinal region, it was hard, nodulated, defined closely to the left side, but somewhat undefined towards the right mesial line. The sigmoid flexure could be traced to the tumour, which seemed to be attached to it. A history of three years' suffering was given during which the rigors of intestinal irritation and obstruction and bladder irritation gradually, but steadily, increased in severity. On December 17th, Mr. Barton operated for the removal of the tumour. An incision about three inches long was made in the linea alba just above the pubis. Through this he quickly obtained room to explore the pelvis, and ascertained that the tumour had no anterior attachment to the bone. The peritoneum was then opened and the tumour was found to surround and grow from the sigmoid flexure of the colon. The tumour was partly excised and the remaining portion firmly ligatured, the ligature being brought out of the wound. The patient recovered, the artificial anus being fully established on the fifth day. The tumour sloughed out. One month after the operation the patient was able to be up in an arm-chair, and expressed himself much better than before the operation, on account of the relief from the irritation of

(a) "De Augmentia." Fourth book, Chap. 11., p. 391. Spedding's edition. London, 1868.

the bladder, and his simple restoration to appetite and sound sleep. Now, three months after the operation, there was no sign of a return of the disease which was carcinoma or alveolar sarcoma.

Dr. SCOTT, who made sections of the tumour, said it was composed of epithelial-like cells, had a carcinomatous appearance, and in that view would be a secondary growth, but no primary growth was discovered, so that in the alternative he regarded it as an alveolar sarcoma in which the cells were of an epithelial character.

Dr. HENRY KENNEDY observed that statistics showed the sigmoid flexure of the colon to be the most common part affected. The relief of the urinary symptoms by the treatment was remarkable.

Mr. W. THORNLEY STOKER would make the incision not in the linea alba, as Mr. Barton did, but in the left semilunar line, not only from the vicinity of the line to the tumour, but also because of less close attachment in that situation than in any other.

Mr. BARTON, in reply, confessed to a strong prejudice in favour of making the incision in the linea alba as giving least trouble and as the lower part when he got down to the pubis led him into the areolar tissue for which he aimed.

EXCISION OF THE TONGUE FOR EPITHELIOMA.

Mr. KENDAL FRANKS read a paper on a case of excision of the entire tongue, the left tonsil and part of the velum palata for epithelioma. In the operation which he performed in January last he divided the cheek from the left angle of the mouth to the anterior border of the masseter muscle to obtain room. The attachments of the tongue to the floor of the mouth and to the lower jaw were divided by means of a galvanic cautery loop without hæmorrhage. A supra-hyoid puncture was then made into the floor of the mouth, and a galvanic cautery loop introduced through it was made to encircle the organ as far back as possible so as to divide the tongue at its base. No hæmorrhage followed this division. The left tonsil, anterior pillar of the fauces, and the greater portion of the left half of the palate were removed with Paquelin's thermo-cautery. A little bleeding from a palatal twig had to be arrested. On 19th February a hard and diseased gland was removed from behind the angle of the jaw and had to be dissected off the internal jugular vein for about an inch and a half. This wound was quite healed in a few days. The mouth healed rapidly, except for a small piece far back on the left side of the epiglottis extending forward to the level of the tonsil which progressed slowly and is not yet cicatrised. The pain which before operation was intense has disappeared, and the patient though weak and disinclined to leave his bed is quite comfortable. The electrical apparatus employed consists of three storage batteries devised by Mr. Prescott, of Dublin.

Dr. ASHE's experience led him to approve of the thermo-cautery scissors as the most satisfactory instrument for removing the tongue in the easiest manner and without hæmorrhage.

Dr. WARREN approved of Mr. Frank's mode of operation as superior to all others. It was perfectly bloodless, and the tissues were cut through instantaneously. To him the *écraseur* seemed a method of slow torture. On account of the extent of the disease in the present case a free incision in the cheek became necessary.

The PRESIDENT held that where the disease was extensive, and even where it was certain to return, the best course was operation, as the return of the disease, though fatal, would make death less painful. All the patients he operated on were placed in the recumbent position and under the influence of an anæsthetic. The adoption of McEwen's tracheal tubes obviated the danger of hæmorrhage, and allowed the administration of an anæsthetic. He always used the thermo-cautery scissors, as the cold or unheated blade passing beneath the part to be severed helped to lift and support it towards the heated blade. In some of his operations he had secondary hæmorrhage, which was prevented since adopting the plan of not having the scissors quite so hot as before during the transverse cutting. He never passed a ligature through the tongue, but seized it with a forceps invented for the purpose by Charriera. He usually slit the cheek, a procedure which he accredited to Mr. Colles. To the galvanic wire *écraseur* he objected as it was impossible to tell whether the diseased situations were not merely cut into instead of being eradicated, and also because the

battery for heating the wire could not be depended on. He agreed in condemning the *écraseur*.

Mr. THOMSON speaking from his experience of the thermo-cautery preferred the hot knife or the wire to either the ligature or the ordinary *écraseur*. With the hot knife should any portion of tissue remain infiltrated with disease there was the ability to go further with the operation at once, which was not so with the *écraseur*.

Mr. STOKES having read a communication before one of the London societies on the subject of excision of the tongue by the *écraseur*, was glad to find many English *confères* endorsed his views. In a record of twelve cases there was not a single one of secondary hæmorrhage, and deaths were much rarer after the *écraseur* than any of the cutting operations by the cautery. The absence of moaning and groaning during the operation was remarkable. Sir James Paget had drawn particular attention to the operation as practical and painless, sensibility being destroyed by pressure on the tongue. Therefore, though the operation was prolonged, the term "slow torture" was inapplicable. Statistics had proved it to be safer than any other and that after it secondary hæmorrhage was extremely rare. Celerity in dividing the tissues he did not consider an advantage as where they were slowly divided there was less chance of secondary hæmorrhage, a disastrous sequela. Dividing the cheek was recommended long before Mr. Colles was known as a distinguished surgeon. An important aid was a traction ligature of strong silk through the base of the tongue to draw it forward and ligature the bleeding vessel if secondary hæmorrhage ensued.

Mr. W. THORNLEY STOKER condemned the use of either the ligature or the *écraseur* as methods worthy only of the middle age of surgery. The small proportion of fatal results after the *écraseur* was due to the fact that of late years its use was confined to cases which would have had a favourable termination whatever means were adopted.

Mr. ORMSBY could not understand the sense of such language as base, bloody, and brutal applied to the operation. He had never used anything else but the wire *écraseur* for the removal of the tongue in his operations, and in none did it appear to deserve such sweeping condemnation, and his experience was that of the entire surgical staff of the Meath Hospital. He concurred with Mr. Stokes that removal by the *écraseur* was not so painful as was supposed by those who had not performed the operation, and was less likely to be followed by secondary hæmorrhage than that advocated by Mr. Frank. The propriety of removing the tongue affected with cancer was doubtful as giving the patient false hopes, the disease being certain to return.

Mr. FRANKS, in reply, contended that the instrument which would work most quickly was the great desideratum.

CARBOLIC TREATMENT.

Mr. CAHILL in a paper on carbolic treatment contended that the question of fermentation in wounds was not really important. The vitalised fluids, blood serum, lymph, and pus, never, he maintained, fermented until they died, and when dead the only proper treatment was to remove them. The cause of death was in most cases dead contact or foreign body. Foreign bodies of different kinds exercised this action in different degrees. Bodies capable of absorption, water and saline solutions, seemed to have little influence. Air, in quantities incapable of absorption, was a violent lethal agent, as testified by the phenomena of canalisation. Smooth polished bodies seem to be less fatal than rough, as seen from the different effects of different sutures. Poisons, organic bodies, blood clot, sponge, have so little of the energy that the forces of life and vascularisation are able to triumph over those of death, and the body becomes organised. Pus is a moribund stage of existence of the vital fluids—a state of injured vitality. A foreign body collects around itself a layer of this moribund material, and if the lethal influence is prolonged this layer will die, as shown by the putrefaction in necrosis. From studying the successes and failures of carbolic treatment, he thought that its antiseptic properties were unimportant. It really acts as a local devitaliser, and, by suspending vital action, prevents suppuration and intense inflammation. It would therefore be much less successful in cases of a low type—indolent ulcer, cold abscess, and particularly threatened gangrene. But it also possesses the very notable property of increasing the absorption power of granulating tissue, as

demonstrated by the researches of Haack, of Leipsic. In the light of this discovery, we can account for the apparent innocuousness of carbolic foreign bodies, dead pus, sphacelus, catgut drainage-tube, protective cotton-wool. It is quite evident that if the absorption influence prevails the layer of dead or dying material will not collect around a foreign body but will be carried off in the circulation. The statistics of treatment show encouraging results only in cases of high vitality or intense inflammation. In cases of low vitality, success is generally brought about by the vitalising influence of irritants, pressure, rest, or position. He put forward Billroth's iodiform-with-scraping treatment of chronic abscess as a pertinent instance. As evidence of the devitalising influence of carbolic acid, might be adduced its effect on the hands of the operator, its action on the skin of the subject; its action in skin diseases, at once astringent and anti-pruritic; finally, its obnoxiousness to amœboid life.

Mr. THOMSON pointed out that Lister was by no means confined to the use of carbolic acid in his treatment, but used perchloride of mercury, eucalyptus, thymol, &c. He dissented from Dr. Cahill's conclusions, and said that Lister's system had the effect of reducing the death-rate and practically wiping out in surgical treatment pyæmia and septicæmia.

Mr. W. THORNLEY STOKER thought Dr. Cahill's point was to give a new explanation of the way in which the effects ascribed to Listerism were produced.

Dr. CAHILL said he did not attack carbolic acid, but Listerism, carbolic acid being in proper cases a very valuable drug. He quarrelled with Lister for using it indiscriminately in all cases, and thought Lister had done a great deal of harm by introducing antiseptic surgery. No doubt Lister used thymol, eucalyptus, &c., but he had gone back to carbolic acid, as mentioned in Cheyne's "Surgery," which, according to Lister himself, was the best source of information as to his system.

The Section adjourned.

OBSTETRICAL SOCIETY OF EDINBURGH.

JUNE 11TH, 1884.

Dr. PETER YOUNG in the Chair.

SPECIMENS.

IN the absence of Dr. Angus Macdonald, Dr. MILNE CHAPMAN exhibited ovaries and tubes from a case of salpingo-oophorectomy; microscopic sections of mucous membrane from a menstruating uterus, thirty-six hours after the commencement of the flow, and from a healthy uterus; microscopic sections of vulvar lupus.

Dr. S. KEITH exhibited three malignant ovarian tumours, two small ovarian tumours showing broad ligament cysts; also a tumour from a patient who had been in bed for ten years, but is now up and able to be about. Dr. Keith also exhibited a fibroid tumour weighing fifteen pounds, the removal being followed by recovery. There were scarcely any adhesions, and the tumour had only been growing for, at most, eighteen months.

Dr. M. MURRAY read a paper by Dr. CURRIE, of Lydney, on

ANTE-PARTUM HÆMORRHAGE.

After stating the great practical interest connected with hæmorrhage during labour, Dr. Currie then described the following case, which, however, did not occur in his own practice, but as it was the object of an inquest, gives it considerable interest:—In March Mr. R. was summoned to Mrs. H. on account of flooding. He arrived at the house at 6.30 p.m., and found that all bleeding had ceased. The woman's clothing was very slightly stained, and her pulse was of fair strength, and normal as regards rate, being about 70. There was a total absence of labour pains, and the os was not at all dilated. The patient had flooded in the early part of January, but the bleeding soon ceased under the usual treatment. On this occasion she was apparently considerably alarmed, and her feeling of dread was not lessened by the women about her, who prognosticated that the baby would be like a monkey, owing to the fact that some months before a monkey had jumped suddenly upon her. Owing to the parents' anxiety, Mr. R. remained in the house and watched her till 9.30, and as by that time there was no evidence of commencing pains, as the os was undilated, and as there was not any occurrence of hæmorrhage, he decided to leave her. Before going home, he gave instructions that the patient was to be kept strictly

quiet in the recumbent position, and he told the midwife to apply cold clothes to the abdomen and vulva if there was any return of the bleeding. He told the woman to send at once in the event of hæmorrhage recurring or labour pains beginning, and he administered an opiate. About 5 in the morning of the succeeding day, Mr. R. was again sent for, but on his arrival at the house the patient was dead. She had, contrary to orders, got out of her bed at half-past three; up to that time there had been no recurrence of hæmorrhage, and immediately on her assuming the erect position, there had been a sudden gush of blood, she got very faint, said she was dying, and expired before help could be procured. The friends asserted that the doctor should not have left his patient on the previous evening, and that her death was due to neglect. Under these circumstances, an inquest was ordered to be held, and I was requested by Mr. R. to attend the post-mortem which was made by Mr. C. The uterine walls were unnaturally thin, and the placenta was attached to the anterior wall, fundal and meridional overlapping to a very slight extent the lower polar circle. At the lower and right margin there was separation to the extent of half or three quarters of an inch, and there was a recent dark clot. The placenta was extremely friable and broke down in the attempts to detach it, and there were some old fibrinous adhesions between it and the uterine walls. On laying the amniotic side open a full grown male fœtus was found in Nægile's first position. The os was dilated to the size of half-a-crown or rather less. The heart was loaded with fat, and especially so on the auricles. There was nothing remarkable about the valves or cavities, but the ventricle was very greasy on section, and under the microscope, advanced fatty degeneration was found. At the inquest Mr. R. stated the history of the case, and treatment he had adopted, which the coroner remarked did not appear to have been very successful. Mr. C. stated the results of the post-mortem, but said that the heart disease was not sufficient to account for death, and that Mr. R. should have plugged the vagina. The Coroner in his summing up said that there could be no doubt that the woman's death was due to her not having been plugged, and that had this measure been adopted Mr. R. would have left his patient in perfect security. Acting on his advice the jury censured Mr. R. for error of judgment and neglect.

Dr. PETER YOUNG, after referring to accidental hæmorrhage, remarked that the separation of the placenta may take place without uterine contraction, as in those cases where the central portions may separate without detachment of the margins. He held that accidental hæmorrhage is more serious than placenta prævia. He animadverted on the statement made by the coroner as to the treatment by plugging the os, and advocated the principle of emptying the uterus at once by dilating the os and turning. Plugging is dangerous, as hæmorrhage may continue even when the head is far down in the vagina. Dr. Young further gave the details of several cases, showing the futility of plugging, and enforced the line of treatment just mentioned.

Dr. NAPIER thought that Dr. Young had exhausted the methods of treatment, but held the opinion that it would be impossible to lay down hard and fast lines of treatment applicable to all cases.

Dr. PLAYFAIR objected to some of the treatment proposed by Dr. Young, but in the main supported the treatment of the cases under discussion.

Dr. P. A. YOUNG made some remarks on the action taken by the coroner, and expressed his delight that there were no such officers in enlightened Scotland.

Dr. UNDERHILL in remarking on the case, held that the treatment adopted was perfectly justified under the conditions related in the paper, and expressed his entire sympathy with the medical man engaged in the case. He also thought that each fellow was perfectly justified in expressing his disapproval of the position taken by the coroner and his remarks on the case, and also his sympathy for the medical man in the case.

Dr. L. NAPIER then read his paper on

PUERPERAL ALBUMINURIA, REFLEX PARALYSIS, AND ECLAMPSIA.

After discussing the causes of puerperal albuminuria, Dr. Napier went on to detail several cases which had come under his notice.

On the motion of Dr. Peter Young the discussion of the paper was deferred to the next meeting.

Special Articles.

A UNIVERSITY FOR BRITISH BURMAH.

THE rapid growth of British Burmah, and the rising importance of Rangoon in particular (now numbering some 130,000 inhabitants), has suggested the necessity for the extension of the educational movement, which commenced in earnest only a few years ago. There has however lately been an earnest movement on the part of the European population, clergy missionaries, the higher officials, &c., to obtain Government sanction and assistance for the founding of a University and College on the basis of the Elphinstone and Grant Medical College of Bombay, or that of University College, London. About five years ago the Chief Commissioner of British Burmah yielded to a generally expressed wish for the introduction of the English School Board system, and the establishment of an Educational Syndicate was the result. This body, acting under the presidency of the Judicial Commissioner, Mr. Jardine, has been doing a good deal of excellent and very useful work. Indeed, it has so successfully performed its task that both Europeans and natives interested in the cause of education have come forward with an offer to found a university, and endow scholarships, but owing to a belief that a Syndicate body could not hold money for these purposes, the flow of benevolence has been checked. To meet the difficulty, one of two things has been proposed—either that of the incorporation of the Syndicate, or the creation of a body armed with the necessary powers for the promotion of the higher education of the people and the foundation of professorships and scholarships. The Government has been approached and strongly urged to sanction the work in hand. The Burmans are in favour of an appeal to the Government, for centralisation has everywhere taken deep root amongst them, since it was adopted from the time of the conquest of the country, and remains a fixed idea. A step of this kind is certainly only a question of time, as the natives are eager for education and fully sensible of its advantages. They know that if they could proceed to obtain a college education, they could easily qualify for those public appointments thrown open to them, but which, owing to certain impediments—as that of having to go to Calcutta to obtain a B.A. degree—they are handicapped in the race. The Educational Syndicate is greatly in favour of an extension of education, and it has been doing what it could to promote education by appointing only certificated teachers. It has undertaken the work and labour of examining and granting qualifications to teach; indeed, it was constituted for the purpose of directing and controlling the public examinations to be held under the grants-in-aid rules, and for the purpose of promoting the study of medicine, engineering, law, and the technical arts. With enlarged powers, it could do a great deal more, for it has expressed an anxious wish to assist Burmese students to proceed from the lower to the higher schools and colleges, and thereby qualify in science, art, law, and medicine.

Owing to the efforts of the present and former Chief Commissioner, much has been effected in the way of abolishing the old superstitions of the Brahmin astrologers, who professed by charms and incantations to cure disease, remove deafness, dumbness, distortion of the limbs, &c. But the medicine men who have sprung up in their places are lamentably ignorant of anything approaching to a scientific knowledge of medicine or the healing art. In short, they are expected to possess only a few primitive notions of either one or the other, as will be gathered from the following "Medical Thesis," the pass examination paper of Marichetty Pundit, a native attached to the palace of His Highness the Maharajah of Mysore, and a former pupil of a surgeon practising in Burmah. It appears in the shape of questions and answers as follows:—

1. What is *Rasayana* or *Electuary*? It is a medicine made of several drugs that have the properties of increasing the healthy secretions or fluids in the animal economy.

2. What is meant by "natural term of man's life"? It is defined to be the co-existence of life received in fetal stage from parents, with that of the body, and the healthy duration of both till its extinction.

3. What is a body? It is a condition wherein all the

organs, internal and external, together with the extremities, are complete and normal.

4. What is life? It is the blood that originates from the heart and nourishes every part of the body by its circulation.

5. To what length of time will the body be healthy and in good condition? As long as the blood is kept healthy and good.

6. To how many kinds of danger is life exposed? (a) Natural diseases; (b) poisons; (c) air surcharged with poisonous impurities; (d) loss of blood by injury, &c.; (e) famine and starvation; (f) thunder and lightning, and fear.

7. How is the so-called life (blood) maintained? By (a) food, water, (b) medicines, and (c) pure air.

8. How is death brought about? By (a) loss of age, (b) diseased condition of blood, (c) anæmia, (d) loss of blood, (e) disordered condition or the total stoppage of action of secretory and excretory organs, (f) and by accidents.

9. What means are to be adopted to avert the immediate death, and to prolong life for the natural term allotted to it? (a) Charitable deeds, as food distributing, &c.; (b) good moral conduct; (c) being always in the thought of doing good to others, as in the proverb, "Do unto others as you would do to yourself;" (d) sincere piety; (e) charity; (f) gratitude; (g) drugs to ward off diseases; (h) good society. If unable to follow the precepts above given, one should live and prolong his life by the grace of God alone.

10. What are the important things necessary to prolong the natural term of life? Numerous may be the ingredients that conduce to the increment of life, of which milk is the essential thing. Examples for this: A small finger-sized rat with its own milk nourishes its young ones, so also does the elephant of enormous size nourish its young.

11. How many kinds of strength are to be found in the body? Three kinds, viz., (a) nervous strength or power; (b) muscular strength or power; (c) vital strength or power. (From blood).

12. What are organs? Organs are divisible into those of *sensation* and *motion*. Organs of sensation are divided into: hearing, touch, sight, taste, and smell. Organs of motion are divided into: speech, motion, locomotion, expulsive action of rectum, &c.

13. How improve the organs of sensation? By the use of ghee or other oily substance one can improve his brains (hypothesis). By the use of milk body is well developed, and also life is prolonged.

14. What are the agents which void sensory organs of health? Narcotics chiefly. Diseased state of blood as well.

15. What must be observed to keep the organs of sensation in perfect order? Use of butter milk and honey, as these maintain nervous system, and they do not possess any narcotic properties.

Medicines to prolong Life.

Amurthavally (Gulancha), Kallangadalay Baroo thokkoos, Misakshe Guggula (Balsamodendron Myrrha), Alalay kayee (Chebulic Myrobalans). Pound each of these separately into a fine powder and mix equal quantities of the powders. To the whole bulk thus formed add its weight of sugar, mix well and preserve it in a wide mouth bottle. Dose $\frac{1}{4}$ a drachm twice a day. Medical uses—In general debility removes old standing diseases from the system and restores it to a healthy condition.

Medical properties of the drugs—

1. Gulancha, removes fever and strengthens muscular fibres.
2. Kallangadalay baroo Thokkoo, demulcent.
3. Mysakshe Guggula, mild stimulant, carminative expectorant, alteratives, and general tonic.
4. Chebulic Myrobalans (Alalay koy), alterative eliminative of mild nature—tonic expectorant and ultimately acts as astringent.—Diseases—fever, womb diseases, hemorrhage, cough, constipation, asthma, consumption, tympanitis, dropsy, &c.

Infusion of Gulancha (Murry Chetty's Formula.)

Take of—Gulancha 1 drachm, coriander seeds 1 drachm, liquorice root 1 drachm, rose petals (dried) 1 drachm, lime peel $\frac{1}{2}$ a drachm, cardamom seeds $\frac{1}{2}$ drachm, boiling water 8 ounces. Infuse for half an hour and strain.—Dose, 1 ounce 3 or 4 times a day, therapeutic uses. In puerperal fever,

continued fever, remittent fever, inflammatory fever, and intermittent fever, &c.

It will be gathered from these extracts, that Burmahs at the present moment are very ignorant of medicine, they neither possess the means of educating men for fulfilling the commonest duties of our profession, nor is Burmah in a position to bestow a legal qualification upon any one to practise medicine, or surgery in England.

INTERNATIONAL HEALTH EXHIBITION.—I.

INTRODUCTORY.

In the following series of articles it is intended to call attention to those features of the great Exhibition at South Kensington which are of especial interest from the point of view of medical practitioners, and to describe such of the exhibits as it may be useful to our readers to possess a knowledge of. We do not propose, nor, indeed, would it be possible, in the limited space at our command to enter on a general description of the Exhibition; for, worthy as it is of being thus treated, it is far too vast in its proportions for anything further than brief accounts of selected articles to be within our power. Those who have already paid a visit to the collection will at once appreciate the difficulty of writing a report upon it; on every hand are to be seen objects of the greatest interest, appliances of the most useful kind, and foods having the most valuable properties. Indeed, the profusion of food stuffs exhibited becomes at length bewildering; and nothing less than an orderly classification of the innumerable varieties of different articles brought together in the building will enable one to gather anything but a confused idea respecting them. In the same way, sanitary appliances, domestic stoves, and the like are shown to an extent that has not been witnessed in even special exhibitions of these classes of fittings, unless exception be made in the case of the Smoke Prevention Exhibition of a year or two ago. The array of sanitary house arrangements is of an unusually complete and comprehensive character, and when studied together with the model houses, now almost completed, will afford a considerable amount of instruction to even casual observers.

It is still too early to speak in definite terms of those sections of the Exhibition devoted to furniture and furnishing, and personal hygiene; for a good deal yet remains to be done ere these parts of the display can be said to be finished. More than enough, however, is already in place to engage the attention of an ordinary sight-seer for a considerable time; but for the purposes of description we shall commence our account with the sanitary appliances, drainage apparatus, &c. In connection with this; also, it will arise to speak of the bread manufacturing exhibits, the importance of which in regard to the public health can hardly be understood by those who have no knowledge of the reforms made within even very recent times in the construction and working of general bakehouses. In the same way, too, great interest attaches to the show of dairies in working order, these institutions being, also, in their present improved form, of very recent growth; and so on, throughout the Exhibition, there is very much to interest and excite the earnest attention of every

individual visitor; and in future articles it will be our object to point out the special features demanding notice.

SANITARY SECTION.

In the exhibits relating to sanitation proper, the first things we noticed were some admirable architectural plans of model dwellings for the poorer classes, which deserve a more prominent position than that in which they are placed. The water companies make a very complete exhibition, with maps and plans of their pumping stations, service reservoir, and area of supply, besides specimens of filter-beds, and, what is more practical, the water itself. The mechanical accessories of water supply are also shown, and the whole is pleasantly situated in an octagon building furnished most appropriately with a fountain. The Native Guano Company have a building all to themselves, exhibiting models of their works at Aylesbury, and specimens of the effluent of sewage treated by the A.B.C. process; the precipitated sludge, deprived of moisture and heated, is said to constitute a valuable manure, which fetches £3 10s. a ton. Specimens of cabbages, radishes, asparagus, &c., grown on land fed by this manure, are also on view, and seem to be quite equal in point of fineness to the agricultural products of land treated by irrigation.

Of exhibits relating to ventilation, Thomson's exhaust ridge tile is an ingenious contrivance to utilise the roof or ridge of a house for purposes of ventilation, the only structural addition necessary besides the tile itself being the adoption of air-flues from the rooms in connection with it; to prevent too rapid change of air, valves, connected with a column of mercury, are placed at the outlets. Ellison's conical brick ventilators are shown. Lamb's cowl system, which consists of flues from each room leading to a large cowl situated at the top of the house, which acts partly as an inlet and partly as an outlet, is subject to the criticism common to all cowls, viz., uncertainty and variability. Several specimens, more or less efficient, of glass louvres and circular ventilators are shown.

Coming now to drainage, we notice an admirable model of house drainage by King, showing the emptying of rain and bath-water, cistern waste, scullery and housemaid's sink over a gully outside the house, a full-bored ventilating soil-pipe taken above the eaves, an intercepting-trap and inspection man-hole between the house-drain and the main-drain, and an air-inlet to the access-chamber. Broad's air-inlets to drains are also exhibited. What is called the "Edinburgh air-chamber sewer-trap" is apparently a variety of the "midfeather," and seems too large, unwieldy, and apt to favour deposit and require constant cleaning. A disconnecting man-hole of Houghton shows no superiority to the well-known one of Roger Field. Buchan's traps are exhibited at a special stand in another part of the building, and appear to maintain their high place. Dean's gully-traps, with their moveable buckets, are shown, and also Stanford's linseed oil method of jointing drain-pipes.

In the East Annexe, a very interesting collection of sanitary appliances is shown, water closets, chiefly of the valve variety, are exhibited in great number, and, though no new principle of construction is exemplified, yet several minor points of improvement in the matter, chiefly of flushing and of disconnection, are brought into notice. Thus, Boetel's Brighton closet has two inlets to the pan for flushing purposes; Jenning's a triple flushing arrangement, by which the water is directed along the rim on both sides and directly downwards; Stidder shows a plan of a siphon flusher, by which the closet cistern is emptied automatically, but we could not judge of its efficiency, owing to our not having seen it at work. A tipping tank cistern is also exhibited, which is emptied by the pressure of the feet on the board below the closet seat; its action, however, did not seem very perfect, and it labours under the disadvantage of not acting unless the cistern is full, so that it is necessary for this to fill between each separate use of the closet. Again, Stidder and Bolding show valve closets in which the overflow from the pan is trapped, in the latter's the overflow is also connected with the supply pipe, and thus its trap is flushed independently of the pan. We cannot commend too highly these improvements in the trapping and flushing of overflows. Stidder also shows various trapped urinals, and an ingenious urinal fitted to the inside of a lavatory. Austin's "Porous Disinfectant," which consists of a block of porous clay enclosing crystals of permanganate of potash, the whole

being suspended in a cistern or water-waste preventor, simply impregnates the water used for flushing with the disinfectant used, and can hardly be said to present any superiority over a powerful flushing apparatus of ordinary water (except in the matter of deodorisation, which is not needed in the case of efficient flushing). The well known Moule's earth-closets are exhibited in their usual efficiency and variety. The Manchester Corporation also display very interesting models and specimens relating to their method of refuse utilisation at Holt Town. The pails, or sanitary receptacles, in which human excrement, house refuse, street sweepings, &c., are collected, are shown full size, and neat models of the "Agitator," "Concentrator," and "Condenser" (the latter intended for the condensation of the noxious vapours set free in the other processes). The final manurial product is sold for £3 a ton, this sufficing to pay the working expenses of the scheme, which are much diminished by the use of other economical bye-products, e.g., soap, candles, and oil.

In our next notice we shall touch upon filters, disinfectants, and the ambulance section.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, JUNE 18, 1884.

THE COMING ELECTION AT THE ROYAL COLLEGE OF SURGEONS OF ENGLAND.

WHATEVER may have been the spirit in which individual members of the Council of the College of Surgeons have hitherto regarded the cry for reform within their corporation, they cannot any longer soothe themselves with the reflection that the demand emanates from an insignificant body of malcontents. That this has been the opinion of the Council hitherto, is clearly shown by the contemptuous disregard paid by it as a whole to the unanimously-approved resolutions passed at the meeting of Fellows and Members held in March last. Now, however, another meeting has affirmed the

conclusions arrived at, and has taken such means for enforcing its requirements as even the power of resistance of the College will find it impossible to withstand. This gathering was held on Thursday last in the rooms of the Medical Society of London, and the chair was occupied by Mr. Paul Swain, who was able to inform the meeting that already more than two hundred Fellows had joined the new Association, the formal inauguration of which they were met to confirm. As yet, however, a very insufficient time has elapsed for obtaining the adhesion of a majority of Fellows of the College, so that before the date of election to the Council next month the numbers who have already joined will undoubtedly be largely augmented. It may be at once taken for granted that every member of the new Association will record his vote in favour of those candidates alone whose opinions on the subject of College government are clearly in accordance with the demands the Council have already refused to consider. Nor need there now be any concealment of the design that is in process of being carried out, to replace the present Council, or at any rate the non-yielding part of it, with gentlemen who are better able to appreciate the necessity of changing with the times. We cannot at once succeed in remodelling the cabinet, but even this year a very important alteration of it can be effected by reinforcing the five members who have, by a recent vote, declared themselves in favour of the views expressed at the March meeting. And here it may perhaps be fair to the majority to suggest that it is in appearance more than reality that they present the front of determined resistance already shown by them; and it is not improbable that the infusion of new blood, the introduction of new Councillors charged with the commission of informing the board concerning the necessities that they do not seem able to perceive, will effect improvement even at once. But this implies that the approaching election will result in the votes of a majority of Fellows being given to candidates whose platform is reform; and it is therefore essential that the views of each candidate shall be thoroughly understood prior to the day of election. In times gone past, anything of this kind has never been called for, no importance of any kind whatever attaching to the opinions of candidates; the interest of election being, as a rule, entirely confined to the then existing Councillors, who were naturally anxious to secure a pleasant companion in each new comer. As a political event the elections were absolutely uninteresting, since no change in the personnel of the Council ever resulted in any alteration of the despotic character of its proceedings.

Now, however, the case is very different; the occasion is altogether unique in the history of corporate societies, and being so, it might be held to justify the employment of unusual measures. It has not been customary for candidates for seats at the Council board to address the electors in any fashion save through the medium of a nomination paper; but, notwithstanding, we may safely assume that some means, compatible with dignity and law, will be found for acquainting the body of Fellows with the nature of the opinions of different candidates now soliciting their suffrages.

Whatever else may happen, the newly-formed Association has clearly a duty before it, to ascertain, for the information of its own members, the views severally held by gentlemen nominated for the vacant seats. Though not made a specific resolution at the meeting on Thursday last, this principle of action was tacitly assumed throughout, and the presence of three candidates for election in July—Messrs. Barwell, Allingham, and Pemberton—at the meeting affords clear evidence of the extent to which they accord with the objects of the Association. Of the remaining candidates, Mr. Gant and Mr. Berkeley Hill are declared reformers; the opinions of Messrs. T. Smith, Lawson, Durham, and Cowell, in this connection, we have not had an opportunity of ascertaining.

The constitution of the new Association of Fellows is quite strong enough to carry out all that it has in contemplation. Its president is Mr. George Pollock, and its council includes the foremost representatives of the reform movement. Its immediate work is in connection with the approaching elections, and it may at once be concluded that the influence it will be able to exert will abundantly suffice to secure the return of five councillors pledged to assist the endeavours of reformers already on the board.

THE CRITICS OF THE BRITISH MEDICAL ASSOCIATION REFORM COMMITTEE.

THE meeting of those who protest against the medical reform policy of the British Medical Association, which, as we recently reported, was summoned to meet at Birmingham, in order to checkmate the assailants who almost all reside in London, was held in the mid-land city, on the 28th ult. If it be any satisfaction to the executive of the Association to know that, by this manoeuvre, they extinguished their critics, they are entitled to the gratification of success, for not a single man is reported to have attended from the metropolis, save the Editor of the Journal, and one other member. In fact, the fifty-six requisitionists who had called the meeting refused to recognise, in any way, the meeting in Birmingham, and left those concerned to defend themselves against an imaginary attack.

This is to be regretted, because a formidable defence had been organised, which was delivered, in order to fill up the time of the meeting, against an absent foe. The Editor endeavoured to show that the Journal of the Association had devoted as much space to the Medical Bill as its importance demanded, but, by so doing, seems to us to have proved the case of those who accuse the Journal of "burking" discussion. We should have supposed that, considering the all-engrossing gravity of the Bill to the profession and to its own constituents, the Journal would have teemed with criticism of its provisions for the last two years, and it would then have been quite unnecessary to produce, as justification, a meagre list of communications thereon, to which insertion had, apparently as a compliment, been accorded.

The chairman of the Medical Reform Committee lent his aid to this defence, by a speech designed to show

that the Bill was as nearly as possible perfect, and needed no amending by the Association, in the course of which he succeeded admirably in elucidating the fact that, with the countenance of the Medical Reform Committee, the Direct Representative is to be reduced to the status of a cipher and, while he is amused with a nice little summer trip to London and a daily luncheon with the great people who are sent forward to the General Council by the Local Boards, he is to be dismissed for the remaining eleven and three-quarter months to the helpless obscurity from which he has been rescued, for a brief period, by the voice of the profession.

As we have said we do not desire to identify ourselves with the way in which some of the spokesmen of the protesting associations have expressed themselves, but, there is no question that their outcry against the Association executive is fully justified. Without doubt the profession has been, either through design or from ignorance of the Bill, kept in the dark as to its details, and when members have expressed their doubts and apprehensions for the benefit of their co-members, their letters, written for publication, have been quietly passed on to the Medical Reform Committee and answered by a polite personal note, meanwhile, the Association has had no policy whatever, except indiscriminate and wholesale laudation of the Bill, its principles, its details, and its framers, and it does not seem to have done anything substantial in the direction of medical legislation save to act as town-crier for Mr. Mundella.

The policy of the Association, in this matter, is, to say the least of it, wanting in energy and in candour, and this trick of summoning a meeting 150 miles from the centre of medical thought to discuss the Bill, is something worse; it is discreditable, unworthy of any great organisation and certain to recoil upon those who now congratulate themselves on their clever strategem.

PROPOSED AMALGAMATION OF DUBLIN SCHOOLS.

THE vacancy in the Professorship of Surgery in the Irish College of Surgeons created by the death of Dr. J. S. Hughes has brought into prominence a proposal for the fusion of the Carmichael College with the School of the Royal College of Surgeons, which suggestion had been the subject of *pourparlers* two years ago. At that time it was generally admitted that by the simultaneous working of two schools within a few doors of each other catering for a class of students who are limited in number much valuable teaching power was running to waste, and that the emoluments of the lecturers were greatly reduced by an unnecessary reduplication of the outlay on working expenses. A fusion of the two schools was, however, found to be impracticable at that time, because it was found impossible to find employment in a single establishment for all the lecturers engaged in the working of the two separate schools, and equally impossible to offer them such compensation as would induce them to retire. The current of events, however, since the question arose has been all in favour of a fusion of the Carmichael

College with the College of Surgeons School. By the lamented deaths of Dr. Reuben Harvey and Dr. Loftie Stoney the Carmichael has since lost two of the chief members of its staff, and it is understood that if an amalgamation be found possible, Dr. Barton will be disposed to retire from the Lectureship on Surgery in the Carmichael. In the College School, on the other hand, a Professorship of Surgery is now vacant, and it is understood that others of the professorial staff would be willing to retire if the arrangements enabled them to do so. The financial condition of the two schools also presented, at the time of the original negotiation, a serious obstacle to their incorporation, for while the lecturers of the Carmichael College were under a debt of several thousand pounds expended on the building of their handsome and commodious new school, the College School professors were entirely free from such incubus; but since that period they have made themselves liable to the College for interest on the money which the reconstruction of their school necessitated. Thus it happens that the two schools are now in a position to treat on approximately even terms as regards financial considerations, and the difficulties personal to the lecturers having been simplified as we have explained, the present opportunity seems very favourable for bringing the negotiation for amalgamation to a successful issue.

Regarding the proposal from a public and educational point of view, and putting out of consideration the candidature of any individual for the vacant Professorship of Surgery in the College of Surgeons, respecting which we are not called upon to express an opinion, we venture to urge the Council and Professors of the College, and the proprietors and trustees of the Carmichael College to take the proposition for amalgamation into their earnest and favourable consideration as a means of improving medical education in Dublin.

It must be manifest to all who have experience of Irish medical teaching, that the plurality of Dublin schools has not worked for the advantage of the student, the public, or the teachers, because the number of those studying in the Irish metropolis has not been sufficient to maintain so many centres of education in a condition of robustness or prosperity, and by making supervision impossible, the plurality of schools has fostered abuses and greatly aided the development of the sham certificate system.

The Schools of the University of Dublin and of the College of Surgeons will, of course, always exist in a condition of greater or less efficiency, because they are, in some degree, independent of the patronage of the student. The Catholic University School will also continue to enjoy the patronage of a large class of pupils who resort thither because of its religious associations, as well as its capacity for affording instruction. The Ledwich School has also, for reasons to which it is not at present necessary to refer, had a large class and an abundant income. But other establishments have succumbed to competition, the School of Stevens's Hospital having been closed altogether, and the old Carmichael School having been obliged to break new ground at the more frequented side of the city in order to save itself from similar extinction. This shrinkage of medical school teaching in Dublin was an inevitable outcome of recent educational reforms, and it

ought to be remembered that the tendency of coming changes of system is all in the same direction. Even now the income derivable by a teacher of average ability and industry in the Dublin School is by no means sufficient to repay men of special quality for the labour and time which the duties require, and many, we might say most, lecturers in Dublin retain their offices much more for the sake of the dignity, and for the introduction to public notice which it affords them, than for the scanty emoluments they receive for their teaching. But when the reductions in the lecture curriculum which have already taken place in other educational centres extend to Dublin, when the decree of the General Medical Council that no more than one course of lectures in any subject shall be required from the student comes to be acted upon under the Medical Bill, it is obvious that a further shrinkage of schools will be precipitated.

We hold that no man could be a good, zealous, well-read, persevering instructor unless he is handsomely paid for devoting his mind to his work, and that, therefore, the existing system of making professorships subsidiary to practice is wrong in principle and unsatisfactory in practice, and, for this reason, we earnestly trust that it may be found possible to utilise the opportunity which now presents itself to reduce the number of teaching centres by one, to strengthen those which remain, and to make the business of instructing the Irish practitioner of the future better worthy the devotion of the best men than, under the present system, it can be.

Notes on Current Topics.

Condensed Milk.

An important decision was given on Friday at Worship Street Police Court, by Mr. Hannay, with reference to the liability of retailers of condensed milk for the purity of the article sold. A firm of grocers in Bethnal Green Road were summoned under the 6th Section of the Adulteration Act for having sold condensed milk which contained only one quarter of the usual proportion of butter fat. The parochial analyst declared that the condensed milk in question contained "only one quarter of the usual proportion of butter fat. The original milk was reduced in bulk from 4.96 parts to one, and had 26.07 per cent. of cane sugar added; originally it contained only 0.52 per cent. of butter fat." It was mentioned that, although proceedings in connection with condensed milk had been taken by authorities in country towns, this was the first action of the kind in London. The defence was that the defendants were relieved from liability under the Act by the 25th section, which said that such exception should take place if the article in question was of the same nature, substance, and quality as purchased by the seller; that they had no reason to believe it was otherwise; and that they sold it in the same state as when supplied, and with a written warranty. A label pasted on the tin had the following words:—"The Company guarantees this to be simply pure milk, obtained from cows fed in the valleys of Switzerland." Mr. Hannay said he was inclined to believe the label was not a warranty within the meaning of the Act, and the

only protection for retailers would be to procure a written warranty from the firm from whom they obtained their supplies. In the present case no one could say who "the Company" guaranteeing was. Although he did not think the defendants were morally guilty, they would have to bear the responsibility, and he imposed a nominal penalty of 1s., with 23s. costs. We trust this decision may become generally known, and that the result of it will be to put a stop to the sale of such condensed milks as are not in every respect equal to the standard of pure milk in their constituents.

Dust and Disease.

VERY serious and justifiable complaints are uttered by the inhabitants of Hackney at the incomprehensible proceedings of their local sanitary authority, in respect to the permission which appears to have been given for spreading dust-bin refuse in their neighbourhood. The public roads between Hackney Wick and Temple Mills are, according to a correspondent of the *Echo*, made the receptacle for ashes and garbage deposited thither from Shoreditch, Bow, and Hackney; and assuming the description to be true of what is occurring, it is difficult to conceive anything more unscientific or more fraught with danger to the public health. It seems incredible that the medical officer of health for the district should permit such a nuisance to exist without raising his voice against it; and at this time of year it is especially important that no facilities for encouraging the spread of disease should be permitted anywhere, and least of all in crowded districts of large towns.

The British and American Associations.

THE American Association for the Advancement of Science will meet on September 4th, and on the 5th a general reception will be accorded by the inhabitants of Philadelphia to members of both the Associations of England and America. A warm invitation to Englishmen to join their American brethren in their discussions has been uttered, and every attempt will be made to contribute to make the visit of those members of the British Association who attend both pleasant and instructive. The Canadian and United States Trunk Lines have combined to give travelling facilities to the visitors from this country, a very material reduction of railway rates having been already announced, while other concessions are expected to be made before the actual time of the meeting in September.

The Rogers Testimonial Fund.

OUR readers will be conversant with the particulars of the inception and progress of this fund, which was started with the view of raising some substantial acknowledgment to Dr. Rogers for his life-long labours to improve the position of Poor-law medical officers. The fund raised for this purpose was closed some few weeks since, and we have now to announce that the presentation will take place on Tuesday next, June 24th, at 3 p.m., in the rooms of the Medical Society of London. John A. Shaw Stewart, Esq., has kindly consented to preside on the occasion.

The Professorship of Surgery in the Irish College of Surgeons.

WE understand that Mr. William Thomson, Surgeon to the Richmond Hospital, and one of the Court of Surgical Examiners in the College, will offer himself as a candidate for the vacant chair of Surgery.

Vivisection.

DURING the year 1883, according to the annual report just issued to Parliament, five hundred and sixty-nine experiments were performed on living animals in the United Kingdom, thirty-four of these being carried out in Ireland. Fifty-five experiments were performed without anæsthetics, and one hundred and twenty-two under certificates giving permission to preserve the life of the animal after recovery from anæsthesia. Concerning this last class of experiments, the report states that in one hundred and fourteen cases the operation consisted of inoculation with various septic matters or morbid organisms, for the greater part connected with an important inquiry into the nature of tubercular affections. No pain was inflicted in these cases except in about fourteen or fifteen instances, in which disease was produced, but which was very trifling. In the remaining eight cases, in which more serious operations were required, as these were effected under anæsthesia, the only suffering in the animals that survived would be that which attends the ordinary repair of a "surgical injury."

Royal College of Surgeons of England Council.

THE full list of candidates for election into the Council of the Royal College of Surgeons of England next month now includes the names of nine gentlemen, viz., Mr. R. Barwell, Fellow in 1853, Mr. W. Allingham, 1857, Mr. G. Lawson, 1857, Mr. T. Smith, 1858, Mr. Berkeley Hill, 1859, Mr. A. E. Durham, 1860, Mr. F. J. Gant, 1861, Mr. G. Cowell, 1867, and Mr. O. Pemberton, 1878. There is thus but one provincial candidate nominated this year, and it is satisfactory to know that this gentleman is fully desirous of seeing those reforms introduced into the College which are rendered imperative by the changed conditions associated with modern progress. In this respect the greater number of the candidates named above are at one with Mr. Pemberton, so that in any case, the Council is certain to be reinforced by at least some who will refuse to follow the illiberal policy which has marked its proceedings for so long a time. It is for the electors themselves to say how many Fellows shall be sent into the Council bearing the message of improvement; and judging from the general interest excited in College matters of late, there can be little doubt but that a very material change in the structure of the College Council is imminent.

THERE are now ten candidates in the field for the Conservatorship of the Royal College of Surgeons of London, the emoluments attached to which are considerable. The election takes place on the 19th inst.

The Medical Bill

APPEARS on the notice paper of the House of Commons as third order for Thursday next, the 19th, the first and second orders being the Railway Regulation Bill and Mr. Trevelyan's Land Purchase (Ireland) Bill. As the Medical Bill is blocked by both Mr. Warton and Mr. Biggar, and, therefore, cannot be taken after 12.30, it is quite likely that the Land Purchase Bill will occupy sufficient time to prevent the second reading of the Medical Bill being taken before this hour, but, in any case, it is open to the Government to alter the notice paper, and put in front of the Bill other orders which would make its postponement to another day inevitable.

The *Lancet* opens a leading article on the subject in its current issue with the assertion that "The Government are determined to press" the Bill, and we believe the statement to be true; but we foresee that it will be useless for them, at this period of the session, to attempt to pass it unless they are willing to meet hostility by such concessions of detail as are not inconsistent with the broad principles of the measure. The second reading, we assume, will not be seriously opposed, but the contest will take place at the committee stage.

We earnestly trust that Mr. Mundella will show himself more suave and amenable to reason than he did last year, for otherwise, we are quite certain that neither this session nor in any near future will a Medical Reform Bill become law.

Bradford Medico-Chirurgical Society.

THE twenty-first annual meeting of this Society, whose proceedings, reported in these columns, often contain valuable papers, was held in the Board Room of the Bradford Infirmary on Tuesday evening, June 10th, for the purpose of electing officers for the ensuing year. The Register of Membership contained the names of 73 gentlemen. The funds in hand were £160, and the books in the infirmary library numbered about 2,100 volumes. Dr. David Goyder, who has given the Society zealous and indefatigable services as honorary secretary for the last twenty years, and to whom much of its success is undoubtedly due, was elected president for the year 1884-5; Mr. T. C. Denby, treasurer; Dr. Rabagliati and Mr. Wilmot, secretaries; Messrs. Miall, Dunlop, Mossop, and Hime, members of council; Messrs. Spence and Phillip, M.B., pathologists; and Drs. Foster and Whalley, auditors.

County Infirmaries in Ireland.

At a recent meeting of the Statistical and Social Enquiry Society of Ireland, Dr. Hercules McDonnell, Surgeon to the Dundalk Infirmary, read an interesting paper on the subject of the "County Infirmaries of Ireland." Each county infirmary exists as a separate unit, controlled by its own board of governors, and answerable only to the grand jury of its own county. They were originally established by Act of the Irish Parliament in 1765, to afford medical and surgical relief to the poor. The cases admitted are in all essentials of the same class as those treated in our metropolitan hospitals. Their means of support are mainly derived

from presentments levied as county cess. The 27 county hospitals had in 1881 1,580 beds available and in use, giving an average to each of 58½; 12,953 patients were treated as interns, giving an average to each institution of 479. The gross expenditure amounted to £29,264 18s. 9d., or an average cost per patient of £2 5s. 4d., and per bed £19 10s. 5½d. The actual cost of the infirmaries to the cess-payer amounts to one halfpenny per £1 of his valuation. For this amount he obtains the advantages of having an hospital replete with every surgical and medical appliance, and maintained in a state of efficiency, which compares most favourably with our metropolitan hospitals. The rooted repugnance which exists to entering a workhouse hospital does not obtain here. No pauperising element enters into the question, nor is anyone disfranchised for accepting such relief.

The Coming Meeting of the British Medical Association at Belfast.

A FOOLISH anonymous writer in a Belfast weekly paper, who appears to have facilities for getting his unwisdom put into print, has, not without malice, been attempting to injure the forthcoming meeting in Belfast, and throw discredit on its managers, by sending duplicate copies of an article that appeared in the paper indicated on the 14th inst., to members of the said Association and others. When the writer makes use of such a sentence as the following—"Sir Andrew (Clark) was to be trotted out as an English medical Baronet; but it so happens that the title was never with so little claim conferred on a member of his profession"—and attempts to ridicule distinguished men by remarks on their Christian and surnames, he furnishes conclusive proof thereby that the managers of the meeting have at least acted wisely in one point, viz., in declining to place in any position of prominence or trust a "gentleman" who manifests so little claim to either. Possibly our Belfast friends knew the manner of man the writer was, and is. We have ourselves previously felt compelled to take exception to the course pursued by the Council of the British Medical Association in conjunction with the Belfast Committee, but we cannot countenance this anonymous effort to injure the annual meeting by petty personal spite.

An Unique Case.

In the amphitheatre of Bellevue Hospital, on May 22nd, Dr. William F. Fluhrer, one of the visiting surgeons, described, says the *Boston Medical and Surgical Journal*, before a number of the profession, a successful operation for the removal of a pistol-ball from the brain through a counter-opening in the skull, and exhibited the patient upon whom the operation was performed. The patient shot himself in the forehead with suicidal intent, and hemiplegia with a semi-comatose condition was caused by the injury. Dr. Fluhrer ascertained the direction of the ball by probing, and then extricated it by means of a counter-opening made at the back of the head, after which drainage was secured by passing a rubber tube through the entire wound. The paralysis

gradually cleared up, and the patient is now, three months after the shooting, in apparently excellent health. An unpleasant feature of the demonstration was the publicity given to it, as an account of it appeared in all the daily papers.

Coffee Colouring.

POISONOUS adulteration of coffee was charged against two firms of manufacturers of New York recently, when the official analyst to the State reported that at one of the works implicated the following colouring agents were employed, viz., French chalk, gum arabic, wood charcoal, a mixture of yellow ochre, clay and hydrated iron oxide, orange chrome, celestial blue, and turmeric. At the other factory there were used Venetian red, yellow ochre, quinia, indigo, and a mixture of Persian berries and ochre. The object of using these various agents was to make damaged coffee look equal to good, and to "cook" unripe berries for market purposes. Prussian blue and lead were also detected in other samples analysed, and even in poisonous proportions in some instances. These experiences in America suggest the possibility that England may not be entirely free from similar practices, and the information may serve to arouse the vigilance of sanitary inspectors in various places.

Sudden Death of a Medical Man.

AN inquest was held on Saturday last, by Dr. Danford Thomas, respecting the death of Dr. W. Fleetwood Dixie, fourth son of the late Sir Alexander Dixie, of Bosworth Park, Leicestershire, and brother of the present baronet. Deceased had suffered for some time from angina pectoris, and was in the habit of using various poisonous drugs, including nitrite of amyl and nitro-glycerine, in order to gain relief. That he was of the danger arising from the too-frequent use of these remedies was evident on a perusal of the memorandum found on his person. A verdict of death from syncope following angina pectoris and from natural causes was returned.

Treatment of Acute Abscess.

IN a recent number of the *Æsculapian* to hand, Professor Smith, of the University of New York, gives particulars of his method of treating these cases, the chief points of which are as follows:—1st. Wash well with soap and water and a flesh brush the skin at the seat of the operation, then douche with a solution of corrosive sublimate, 1 to 500. 2nd. Open the abscess with a knife treated with a solution of carbolic acid 1 to 30, the opening to be of a size to admit the nozzle of a Davidson syringe. 3rd. Force out the contained pus by pressure, when it ceases to flow, introduce the nozzle of the syringe, well disinfected, the edges of the wound being held firmly around it, and distend the cavity to its fullest capacity with corrosive sublimate solution, 1 to 5,000. 4th. Force out the injected fluid by pressure. 5th. Repeat this injection as often as may be necessary until the water flows away quite undischarged. 6th. Lay the cavity open to its full extent, keeping up irrigation with a corrosive sublimate

solution 1 to 2,000. 7th. Cut away all shreds of tissue, and scrape off gently any granulations that may be upon the living surface of the abscess by means of a curette, until a perfectly clean surface is everywhere apparent. 8th. Ligature any small vessels that may be bleeding with carbolised ligatures, thorough irrigation being kept up with the corrosive sublimate solution throughout. 9th. Close the wound with an uninterrupted suture, except at the most dependent point, where a small opening must be left for drainage. 10th. Over the drainage opening place a disinfected sponge to absorb discharge. 11th. Sprinkle the external wound and adjacent skin with iodoform; cover the wound well with folds of gauze between which iodoform is well sprinkled; over the layers of gauze apply a dressing of borated cotton, and if in a limb, secure all by a light plaster-of-paris bandage. In the case reported, that of a man with abscess in the thigh, the result of injury, and large enough to contain a pint, and to get at which, an incision two inches deep had to be made, the suffering and fever before the operation was considerable. Temperature 103°. The day after the operation the temperature fell to normal, and did not again rise to 100°; the pain ceased entirely, the appetite returned, and he enjoyed sound and undisturbed sleep. The patient stated that from his recovery from the anæsthetic he had felt entirely well. The dressing was removed on the eighth day. The wound was entirely closed, and though there was some thickening of the tissues involved in the injury, there was no tenderness. He could walk without pain or inconvenience, and there was a rapid subsidence of the swelling of the part.

Professor Smith estimates that the man was at least saved a month in time by the operation. His experience of this method of treatment is most favourable, and he believes the time is at hand when "the very presence of pus in the practice of surgery will be evidence of the inefficient use of remedial measures." He believes that this method of treatment is also applicable to furuncles and carbuncles, and indeed, to wherever there is evidence of the presence of necrosed tissue.

DR. THOMAS NEDLEY, Physician in Ordinary to the Lord Lieutenant of Ireland, has been appointed to be Surgeon to His Excellency's household, *vice* Dr. James Stannus Hughes, deceased.

AT the recent meeting of the Council of the Medico-Psychological Association of Great Britain, Dr. Eames, Medical Superintendent to the Cork District Lunatic Asylum, was elected President for the ensuing year.

MR. STOKES, Professor of Surgery in the Royal College of Surgeons in Ireland, and Surgeon to the Richmond Hospital, has intimated to the Fellows of the College that he will seek suffrages for the Vice-Presidency in June, 1885.

A COMPLIMENTARY dinner was given on Wednesday last by the medical staff of University College and Hospital to

their colleague Professor Marshall, F.R.S., in honour of his election to the Presidency of the Royal College of Surgeons of England.

CONSIDERABLE interest attaches to the announcement that a comedy founded on incidents in hospital life, by a member of the profession, will be given on the 26th inst., in aid of the East London Hospital for Children. The comedy will be in four acts, entitled "Sister Grace."

THE case of the quack Silverton, referred to in our last, was decided by the Manchester magistrate on Thursday by the discharge of the *soidi-sant* reverend and his medical coadjutor Mitchinson, on the ground that the charge of fraud had not been proved. They will be thus let loose again on the public to pursue their quest of ill-gotten gains.

In the principal foreign cities the rates of mortality per 1,000 of the various populations were, according to the latest official returns, as follow—Bombay 29, Madras 79, Paris 23, Geneva 26, Brussels 23, Amsterdam 25, Rotterdam 40, The Hague 30, Copenhagen 22, Stockholm 23, Christiania 17, St. Petersburg 37, Berlin 25, Hamburg 26, Dresden 28, Breslau 26, Munich 34, Vienna 33, Prague 40, Buda-Pesth 34, Trieste 23, Turin 28, Venice 23, Lisbon 26, New York 23, Brooklyn 16, Philadelphia 20, and Baltimore 17.

THE deaths registered last week in the principal large towns of the United Kingdom corresponded to an annual rate of 19.6 per 1,000 of their aggregate population. The death-rates in the several towns were:—Leicester, Brighton, Newcastle-on-Tyne 14; Norwich 15; Birkenhead, Cardiff, Salford, Bristol, Derby 16; Blackburn, Nottingham, Bolton, 17; Hull, London, Bradford 18; Birmingham, Huddersfield 19; Sunderland, Plymouth, Dublin, 20; Sheffield, Portsmouth 21; Liverpool 22; Manchester, Edinburgh, Preston 23; Glasgow, Leeds 25; Halifax 26; Wolverhampton, Oldham 28.

NOTICES have been posted outside the various Metropolitan hospitals warning the public against the excessive use of mackerel and mild ale at this season of the year, as the larger fish are liable to contain a small worm which would be injurious and likely to create cholera and other diseases. The caution with regard to the drinking of large quantities of mild ale is given specially to the working classes, as the habit causes profuse perspiration and renders the body liable to a chill, which would be likely to lead to serious consequences.

THE highest annual death-rates last week in the large towns from diseases of the zymotic class were—From measles, 4.0 in Wolverhampton, 3.0 in Oldham, 2.4 in Portsmouth, and 2.3 in Norwich; from whooping-cough, 1.4 in Liverpool, 1.3 in Sunderland, and 1.1 both in London and in Cardiff; and from scarlet fever, 2.1 in Oldham, 1.9 in Sheffield, and 1.3 in Leeds. The 35 deaths from diphtheria included 16 in London, 7 in Glasgow, and 3 in Edinburgh. Small-pox caused 40 deaths in

London (exclusive of 20 registered in the Hospital Ship *Atlas*, and in the Convalescent Camp, outside Registration London); also 3 in Liverpool, 2 in Hull, 1 in Birmingham, 1 in Sunderland, and 1 in Cardiff.

Scotland.

[FROM OUR NORTHERN CORRESPONDENTS.]

PREVALENCE OF MEASLES IN DUNDEE.—At a meeting of the Police Commissioners of Dundee, held on the 12th inst., the monthly report of the medical officer to the Board of Health was submitted, in which it was stated that measles was rapidly spreading in the town, and that the spread of infection was largely due to the wilful neglect of sanitary regulations by many school teachers. The neglect of the teachers consisted in their having failed to demand medical certificates from convalescent pupils who had been absent through illness. The medical officer suggested that such offending teachers, especially School Board teachers, who were the chief offenders, should be rigorously dealt with in order to check the spread of infection. The Health Department was in possession of evidence against ten teachers.

THE UNIVERSITY OF GLASGOW AND THE UNIVERSITIES (SCOTLAND) BILL, 1884.—Admitting that in times past Scotland owed much to the Universities, it has been long felt, and the feeling intensifies as time goes on, that the country has paid dearly for any obligations arising therefrom. The present position of the Universities in relation to teaching is a shameful anachronism. If the mode of election of professors is indefensible, how much more indefensible is their claim that, once appointed, they must be protected by the Crown against fair and honourable competition for the rich emoluments pertaining to their offices. The following wail emanates from the University of Glasgow against the Universities Bill:—The *Senatus Academicus* state that they welcome the prospect of any legislation calculated to promote the better administration and endowment of the Universities of Scotland, and they readily acknowledge that several of the enactments proposed in the present Bill are such as, in their opinion, would tend to the better administration of the Universities. They regret, however, that the financial proposals contained in the Bill are open to grave objection. The provision shutting out the Universities from the possibility of any additional aid from the public funds in future, into whatever straits circumstances or accident may bring them, is not, the petitioners submit, in accordance with the main design of a measure for the better endowment of these national institutions. In the Bill the foundation of new Professorships is contemplated; and it is obvious that, with the advance of science and improvements in the methods of education, the foundation of new chairs must continue. The charge, therefore, for retiring allowances is one which must ever tend to increase. In particular, the Commissioners are empowered (1) to establish a fee fund and to provide compensation to Professors injuriously affected by its establishment; and (2) to make regulations as to extra-mural teaching in each of the faculties, a proposal which, in the opinion of the Royal Commission of 1876, could not be carried out without providing compensation to professors for consequent loss of fees. The petitioners submit that it would perpetuate an unfair disadvantage under which the University of Glasgow has hitherto been placed, if an allowance for maintenance were included in the minimum share of the £43,000 to be

allocated to each of the other three Universities, while no similar allowance was made to the University of Glasgow. They, therefore, pray that the Bill in its present form may not be passed into law.

THE MEDICAL BILL AND SCOTCH OPPOSITION.—The following paragraph appeared last Wednesday in the letter of the London correspondent of our contemporary the *Scotsman*:—"That the Medical Corporation and University authorities have, at a conference held in Edinburgh on Saturday, agreed not to offer any opposition to the Bill on general grounds, and to limit their demands substantially to those now laid before Mr. Mundella by the Edinburgh deputation." The truth of the above statement has been denied by the Presidents of both Colleges, the President of the College of Physicians declaring that the Government "troubles are yet to come."

DEATH OF A MEDICAL MAN FROM CHLOROFORM ADMINISTRATION.—We deeply regret to announce the death of Dr. Godfrey MacRae, of North Uist, at Edinburgh, from the administration of chloroform. Dr. MacRae, we are informed was suffering from a tumour at the nape of the neck, for the removal of which he went to Edinburgh, and placed himself under the care of Professor Annandale. While the chloroform was being administered prior to the necessary operation, Dr. MacRae, who was in the prime of life, suddenly died.

HEALTH OF EDINBURGH.—The mortality in Edinburgh for the week ending with Saturday, the 7th inst., was 94, and the death-rate 20 per 1,000. Diseases of the chest accounted for at least 40 deaths, and zymotic causes for 16, of which 1 was due to fever, 2 to diphtheria, 2 to scarlatina, and 2 to measles, the intimations of these diseases for the week being 10, 6, 27, and 27.

GLASGOW DEATH-RATE.—For the week ending with Saturday, the 7th inst., the mortality of Glasgow was at the rate of 25 per 1,000 per annum, as compared with 24 in the preceding week, and 34 in the corresponding week of last year.

ACCIDENTAL POISONING NEAR JEDBURGH.—A sad case of accidental poisoning took place on Saturday, the 7th inst., at Upper Nisbet, about four miles from Jedburgh. An old man named McDougall, who resided there, feeling unwell, took what he believed to be a dose of Epsom salts, but what unfortunately turned out to be nitre. Death resulted in about an hour afterwards.

Medico-Legal Intelligence.

A QUESTION OF FEES.

At Crewe, on the 9th June, Mr. Thomas Hughes held a Special Court to try an action, which had been sent down by the Superior Court, in which the plaintiff, Mr. Charles Frederick Sutton, Surgeon of Holmes' Chapel in Cheshire, sued a Mr. Archibald Young, of Manor House, Middlewich, for £74 16s. for medical attendance. Both were represented by counsel, and the case was tried with a jury. The plaintiff, it appeared, had a branch surgery not very far distant from the defendant's house, and where he was represented by an assistant, his own residence being five miles away. He charged £1 1s. for visit for himself, and 10s. 6d. per visit for his assistant. The plaintiff alleged that he was asked to pay particular attention to the defendant's wife during accouchement, and also to look well after the child, which he was also called upon to attend. Five guineas was the fee for accouchement, and two guineas for administering chloroform, but his visiting fee included medicines. In cross-examination, the plaintiff stated that his fee depended upon the position of his patients. He was supported in his statement as to the charges not being excessive by three medical men, and they also agreed in their

opinion that the position in life of the patient, as a rule, regulated the doctor's fees. For the defence, it was denied that special attention had been desired, and three other medical men thought the charges excessive, except in case of special night visits. One of them thought the charge for giving chloroform should not have been an extra.

The jury found for the plaintiff for £62 2s., and the judge gave a verdict for that amount and costs. In summing up, the judge said that, as regarded the general principle upon which charges were made, doctors, like lawyers, had to consider the position of the persons who employed them. For ourselves, we are strongly of opinion that chloroform ought in every case—midwifery or otherwise—to be an extra, and charged for accordingly, and we regret the jury did not see their way to give their verdict for the full amount claimed, especially if the plaintiff was able to show the charges made were such as he was in the habit of charging for similar services. Doctor's fees must be regulated by the value each places on his own services, and the demand upon his time, as well as his skill, will soon enable him to sustain the fees asked.

Correspondence.

THE FELLOWSHIP OF THE ROYAL COLLEGE OF PHYSICIANS OF LONDON.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—About a quarter of a century ago, the Council of the College of Physicians, wishing to introduce "energy and increased vitality" into the management of their establishment, chose about a dozen M.D.'s in the prime of their lives, and conferred the honor of membership upon them without examination. Such gentlemen naturally presumed this would soon lead on to the Fellowship. Since that period, very young men, really commencing their work, and not chosen as the others, have been made Fellows. Kissing goes by favour, and it would seem something of the kind goes on elsewhere; very few of those gentlemen who were honoured by the College with the title of member, have been proposed for the Fellowship. The Council of the College would act wisely and well, if they proffered the Fellowship to those gentlemen living now, as an act of grace, justice, and right, although it is not improbable that some would refuse the distinction after being "forgotten" to say the least of it for 25 years.

Yours, truly,

London, 11th June, 1884.

M.D.

THE INCREASE OF INSANITY.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—I have no wish to prolong a controversy with Dr. Madden. He has had his say, and I have had mine; but I would propose the following question as arising out of the discussion:—How is it that when medical men want to establish a sickness insurance society, they employ a member of the Institute of Actuaries to make the calculations for them, but when the very same science of probabilities has to be applied to such questions as the increase of insanity, or the increased duration of human life in England, every man considers himself competent to make the calculations for himself, although he may never have spent an hour of his life in the study of that branch of mathematics to which the science of probabilities belongs?

Yours, &c.,

A. W. WALLACE.

THE NEW BANKRUPTCY ACT IN RELATION TO ARTISAN PRACTICE.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—Your leader on the above subject in current issue is pertinent, sensible, honest, and explicit. Of the three learned professions, the medical is the most harassing, unrequited, and best abused of all. *Messieurs les cléricaux*, as the French would say, demand and receive ready money for baptisms, marriages, and funerals, whether the doctor has received payment or thanks for his services in the business of the first and last-named of those stages of life. The lawyer, whether senior

or junior, barrister or attorney, demands from his client "money down" before he appears in court to open his mouth before his worship, his honour, or his lordship. And not infrequently an eminent Q.C., after receiving with his brief a heavy retaining fee, fails to appear in court as bargained and paid for; and if the client is foolish enough to expect the return of a single shilling of the extravagant fee, he is simply laughed at for his simplicity.

As the subject is of the highest importance to that man of all work, the general practitioner, I will, Sir, with your permission, give, in a few letters to your journal, particulars of cases picked at random from an experience of County Court practice extending over a dozen years. In the record there will be nothing so startling or amusing as the story of the "Amateur Casual." But, as an example, I now give the following fact, and to any reader who is curious to know the constituents of the fact—namely, time, place, and circumstance, he shall receive those from myself by correspondence privately through the *Press*.

About eight years ago a doctor was requested to visit a patient at a distance of eleven miles from the doctor's residence. The patient had turned middle life, or reached the period called "elderly." He had been ill two or three weeks, from enteric fever, and was being attended by the "colliery doctor," a gentleman *sine* diploma. The time of the year was early winter, and the morning of his visit the doctor had ridden on horseback a journey of eighteen miles in visiting a special case of moderate urgency. On his return about noon he left his horse at the railway station and took first-class return to the station in the neighbourhood of his call. A walk of four miles in a fair frosty air brought him to the residence of his patient. He sent a messenger for the colliery doctor, who came immediately, and to this gentleman the visitor or consultant gave his opinion and advice. The latter included lyttæ to the occiput and nape of neck, and catheterism to relieve urgency in those regions. The catheter was used in the presence of the consultant, and he departed, to return again "in two or three days." The day was Monday. On Thursday he made his second visit, and between Friday and Saturday the patient died. The deceased man died moderately rich for a miner, his widow as executrix retaining at least £100. The doctor, to whom his "customers" were known, sent in in the course of a few weeks his bill for four guineas, and through gossiping friends the information reached him that the widow had been advised "that when a man died his debts died with him, and she would pay nothing." No reply coming direct from the executrix, he in a few weeks more entered a plaint in the County Court. Having reason to know his "customers," he summoned the eldest son as his witness, and in time the day of trial came. The lady who, under advice, had refused to pay the doctor, employed a solicitor to defend her, and brought a younger son to prove that the doctor having heard of the illness of the patient, had visited him from sheer good nature, or for "auld lang syne." This part of the defence being negatived by the evidence of the eldest son, the solicitor "cast about" for a new line. The doctor in his examination in chief had told the story of his visits and the malady of the patient. And when the defence began to denote a collapse the solicitor became wordy, as if he meant his client and the court to believe that he gave full value for his money. *Inter alia*, he asks, "What do you say again was the cause of death in this case, doctor?" "Effusion on the brain," answers the doctor. "Infusion of the brain?" "No, Sir; confusion of the brain, you may call it, if you like," retorts the doctor. Becoming a little confused, Mr. Solicitor inquires, "How many visits did you make to the patient?" "Two." "How much do you charge for each visit?" "Two guineas!" "The people are poor?" "Yes, what is called poor, respectable working class." "Well, now, is two guineas a visit not an extraordinary charge to people in their circumstances?" "That question requires a full answer, and with the permission of the Court I will answer." The "Court" nodded assent, and then the doctor continued: "It is easily reckoned. From my home in Blanktown to the defendant's in Startown is eleven miles at least. I received a special call, and it was arranged I should call again at discretion. Now if I hire a carriage and pair for the whole distance (the railway being far away) you can count the hire, not to speak of my time. But I will give it to you another way. If a working man employs you to come from Squartown to Blanktown Petty Sessions to defend him, you attorneys charge at least two

guineas, generally three, as your fee. Well now, as it takes as much money to make a doctor, that is, if he is properly educated, as it does to make five or six attorneys, the charge of two guineas is a small charge." There was a pause in the cross-examination, the judge ultimately finding for the plaintiff (doctor), whose charge he considered moderate under the circumstances, with costs against the patient.

So ends our first chapter of County Court Law. "To be continued," as the "penny dreadfuls" say.

I am, &c.,

EXPERIENTIA DOCTE.

Blanktown, 13th June, 1884.

Literature.

THE LAW OF SEX. (a)

IN the early part of the present century Roman antiquarians were anxious to discover by whom the Column of Phocas, "with the buried base" was erected; and some of them proceeded to an exhaustive search of all notice of the column in ancient and mediæval literature. Other antiquarians, however, adopted the prosaic but more scientific method of digging down to the foundation of the column, and were rewarded by the discovery of an inscription which gave all the information required. Our author resembles the first section of the antiquarians, he gives us an account almost of every opinion which has been advanced, from Aristotle downwards, upon the question of how sex is determined. The subject is a very old one, and it is the standing joke of the facetious practitioner to ask the young primipara whether she will have a boy or a girl. After thrashing out all his quotations, with a conspicuous absence of medical knowledge, our author arrives at the conclusion that sex is determined by the "superiority" of one parent, but what that superiority is he does not very clearly explain. He expresses the belief, however, that when the father is "superior" daughters are produced; and the converse in the case of maternal "superiority." The old idea that sex depends on the will of the mother he promptly and properly discards, remarking "it may be left to disconsolate parents with large families, all of the opposite sex to that coveted, to testify as to the truth of the supposition" (p. 33).

It is difficult, if not impossible, to investigate this subject, by inquiries as to human beings. In brutes the female animal has her annual or oftener period of "heat;" and while in this condition permits sexual intercourse to all male congeners presenting themselves. At other periods, however, she angrily resents any such attempts upon her. In the human female there is no period of heat, and intercourse between the sexes is resorted to more generally for purposes of pleasure than of procreation, at almost every period except menstruation. Still there are a few facts. John Hunter has noted that in a large family of girls, with one or two boys, the latter have a feminine character, as if that sex had just been miscead, and conversely with families of boys with one sister. Families of girls are often found in the case of struggling men, who with limited incomes have an annual domestic contribution, either singular or plural. It is an unfortunate fact that in civilised and old countries adult females predominate; but it must be left to statisticians to say how far this is due to a preponderance of natural females or to the proportionally greater thinning of the sterner sex by emigration, war, or accident.

It is to animals whose sexual intercourse is natural and susceptible of control that we must look to for facts, for there is little doubt in so animal a function, it will be for both human being and brute, like case like rule. When caterpillars are fed abundantly in the chrysalis state female butterflies are produced in the proportion of ten to one, while those who are badly fed display a like preponderance of males. Again, Mr. Meehan, of Philadelphia, has shown that in plants the highest "scale of nutrition gives the female (flower) sex, and the lowest scale males" (p. 26). Mr. Giron at a meeting of the Agricultural Society of Séverac (France) proposed to divide a flock of 300 ewes into

(a) "The Law of Sex." With fifty illustrative portraits. By George E. Starkweather, F.R.G.S. London: J. & A. Churchill, Medium 8vo.

two parts, and to produce lambs of an indicated sex. Our author gives the result, which appears to us to hit the centre of the target, the half (of the ewes) that was highly fed, and had young rams, produced females in the proportion of three to two males; the other portion was poorly fed, had rams of mature years, and produced males in the proportion of three to two females, substantially as had been predicted (p. 40).

It appears to us that as a rule all impregnation takes place during the period of about sixteen days after menstruation, and from this up to the next catamenial discharge intercourse is ineffectual. If the impregnation takes place during the first seven or eight days of the former period, girls are produced, if subsequently, boys. This conclusion is furthered by animal analysis, and that the process can be regulated there is no doubt. Sir John Sebright, so well known as a skilful breeder of pigeons, says that he will produce any given feathers in three years, but that he needs six years to produce head and beak; (p. 72), and our author adds very wisely that vastly more care and thought are devoted to the production of perfect horses, cattle, sheep, and pigeons, than to men and women. There are some interesting observations upon sterility, in which the observation of M. Paul Broca is quoted, viz., that human cross-breeds (e.g., mulattoes) are sterile with each other; and this also harmonises with animal analogies. Of the 46 portraits and commentaries thereon we will say nothing. A 8 is a portrait of the late John Stuart Mill, A 9 of the late Sir Charles Napier, and B 19 of the Ex-Empress Eugénie.

AIDS TO PHYSIOLOGY. (a)

THIS unpretending little book is much superior to the ordinary run of small cram-books with which students are now-a-days so liberally supplied. It is specially designed for students preparing for examination, but is free from most of the objections often urged against such compilations. Mr. Lowne, as examiner in the subject at the largest qualifying body in the United Kingdom, should know what is required, and he has a happy knack of telling it. He does not pretend to condense into his little volume everything the student ought to look into, but he furnishes industrious men with a reader and more exact compendium of the important points in physiology than they could expect to prepare for themselves. We have tested this manual by a careful examination of some of the most difficult subjects, and have been much pleased with the lucid way in which they are given. We can, therefore, highly recommend it to students, though we hope that even with so good an outline as this no one will attempt to apply it to uses for which the author does not intend it. To read up the subject at the last it is excellent, provided lectures and laboratory work have not been neglected.

DISEASES OF THE EYE. (a)

ANOTHER and yet another manual on the normal or abnormal condition of the eye, issues forth from the press in quick succession, and which, taken in connection with the work of a Society, whose annual Transactions form a goodly volume, is certainly indicative of an unusual state of activity in the department of ophthalmic medicine. Mr. Tosswell, in the preface to his "Guide to Diseases of the Eye," says that he believes general practitioners to be greatly in need of a book of the kind, since their time is so much engrossed by other matters, and therefore they are unable to turn to bulky volumes devoted to eye diseases. Brevity is with him the soul of good writing, and he carries out this virtue throughout his pages. An instance or two will suffice: Cataract is disposed of in little more than a duodecimo page of twenty-four short lines; it is true he intimates that the general practitioner will do well, when in doubt, to consult a specialist. Phlyctenular conjunctivitis is disposed of in about a page and a-half. Glaucoma receives some more consideration at his hands. We nevertheless doubt the value of compressing the diagnosis and treatment

of obscure and important diseases into 140 small pages. Moreover, we are of opinion that Mr. Tosswell's manual will in no way be found to supersede that of Wharton Jones, published some quarter of a century ago. With regard to the employment of remedies the advice given is on the whole judicious, although a too free a use of atropine is recommended, and without due precautions being taken as to its producing a severe conjunctivitis. We do not at all agree with the author as to the value of excision in sympathetic affections of the eye. Opacities from lead are now rarely seen; the drug has, in fact, almost disappeared from amongst the medicaments of the ophthalmic surgeon. A very full index will be found to greatly facilitate reference.

Mr. George Hartridge, in his manual on "The Refraction of the Eye," has had to deal with a somewhat more abstruse department of ophthalmology, and although he has accomplished his task with that clearness and precision acquired by practice, he can scarcely expect his manual to take the place of others already favourably known to the profession—as, for instance, Morton's handy little volume, the second edition of which we noticed only a few months since. With regard to Mr. Hartridge's first chapter, we believe it to be quite unnecessary. The advanced student of the period is expected to have fully mastered the elements of physical science, optics, before he ventures to present himself for his preliminary. Is it, in particular, wise to abandon old measurements entirely, and simply because in the author's opinion "the metrical system is almost universally adopted." We cannot admit the validity of his (the author's) plea, as amongst English-speaking people, widely distributed over the face of the globe, there will always be found very many wedded to, and bound hand and foot by, the good old-fashioned English inch measurement, and which, by the way, is still the law of the land. It is no easy task, as our author has discovered, to write anything new on refraction of the eye, or furnish students with new methods of diagnosing and estimating errors of refraction. We are not at all surprised, then, that Mr. Hartridge should have been compelled to fall back on the well-known treatises of Mackenzie, Donders, De Wecker, and others, to whom he refers as having furnished materials for his handy and useful manual on "Refraction of the Eye."

Royal College of Surgeons of England.—The following is a list of members of the College who were successful at the Final Examination for the Fellowship on May 29th, 30th, and 31st, and who were admitted Fellows on June 12th:—

Briggs Henry, M.B. Edin., Rodney Street Liverpool.
Bull, G. C. Robins, L.R.C.P. Lond., Dover.
Bullar, John Follett, M.B. Cantab., Southampton.
Dunn, Louis Albert, M.B. Lond., Cavendish Place, Brighton.
Evans, William George, L.R.C.P. Lond., Colchester Street.
Fowler, Walter, Old Burlington Street.
Holthouse, Edwin Hermus, M.B. Cantab., Haledon, Northants.
Jennings, Charles Egerton, L.R.C.P. Lond., Malmesbury.
Kaefer, Jean Samuel, M.D. Bale, Queen Ann Street.
Knaggs, Robert Lawford, L.R.C.P. Lond., Disraeli Road, Putney.
Pearce, George, M.D. St. And., Leicester.
Perks, Robert Howell, L.R.C.P. Lond., Gardner Road, Hampstead.
Rogers, James Macdonald, L.S.A., Berners Street, London.
Sanders, John William, L.R.C.P. Lond., Bethnal Green Infirmary.
Stonham, Charles, Gower Street.
Sutton, John Bland, L.R.C.P. Lond., Gordon Street, London.
Thyne, Thomas, M.D. Edin., The Barons, Twickenham.
White, Sinclair, M.D. Dub., Sheffield (not a Member).

Three other candidates passed the examination, but not having attained the legal age (twenty-five), will receive their diplomas at a future meeting of the Council. Seven candidates failed to reach the required standard, and were referred to their professional studies for one year.

The following gentleman, who passed the examination for the Fellowship in November last, having now attained the legal age, received his diploma as Fellow of the College:—

Collins, William J., M.D. Lond., Albert Terrace, Regent's Park.

Royal College of Physicians, Edinburgh.—The following candidates were successful at the recent examinations of this College, and have been admitted Licentiates (L.R.C.P. Ed.):—

Edmund Barry Denny, Dublin; Thos. Brown Cross, Scarborough; George Samuel Pollard, Norfolk; Thos. Benjamin Lumscombe, Deddington; Edward Tongue Yeates, Balbriggan; Wm. Cae. Gladier Collins, London; James Newton, Manchester; Henry John Clarendon Godfrey, London; Roger David Delahaye Williams, Swansea; Gerald Oscar Hawkins, Teignmouth; George Philip Longman, Southampton; Arthur Richard Rackham, Old Oak, Norfolk; Sydney Robert Lidiard Hall.

Analytical Records.

By PROFESSOR FRESSENIUS.

HUMAN MILK AND MELLIN'S FOOD.

THE following comparative analyses of human milk and Mellin's Food for Infants have been sent us by Professor Fresenius for publication:—

I.—Analysis of a mixture of Mellin's Food, Water, and Cows' Milk, prepared in accordance with the directions, viz., Mellin's Food, 1 tablespoonful or $\frac{1}{3}$ oz.; Water, 2 oz.; Cows' Milk, 6 oz. Or, Mellin's Food, 5.88; Water, 23.53; Cows' Milk, 70.59. Total, 100 parts.

			Water.	Sugar.	Nitrogenous Matter.	Butter.	Salts.
Mellin's Food	5.88	Water .. 78 Sugar .. 4.27 Nitrogenous Matter .. 57 Salts .. 26	78	4.27	57		26
Water	23.53	Water .. 23.53 Water .. 61.03 Sugar .. 2.68	23.53 61.03		2.68		
Cows' Milk	70.59	Butter .. 2.54 Casein .. 3.88 Salts .. 46			8.88	2.54	46
Totals	100.00	100.00	85.34	6.95	4.45	2.54	72

II.—Comparative Analyses of Human Milk and Mellin's Food.

HUMAN MILK.							
ANALYSES QUOTED BY TANNER.				WURTE'S ANALYSES.		LEEDS' ANALYSIS OF 43 SAMPLES WOMEN'S MILK.

RHENS MINERAL WATERS.

THIS water has been introduced into this country since the conclusion of our reports on the "Mineral Waters of Europe," and we give the analysis in order to make our reports complete to present date. The analysis is by Messrs. Wigner and Harland, and the water supplied by Messrs. Lotz, Abbott & Co., of Queen Street, London, agents for the springs in the United Kingdom.

One imperial gallon = 6 bottles, contains—

Total solid matters 16.8 grains per gallon, containing—

	Grains.
Chloride of sodium	60.2
Sulphate of soda	41.5
Carbonates of soda, lime, and magnesia	82.7
Oxide of iron	.1
Silicic acid	trace.

The analysts remark that the gas with which the water is aerated is unusually free from atmospheric air, consisting almost entirely of carbonic acid. It will be seen from the above figures that the water is essentially of a class of table waters adapted for everyday use. Half-a-pint will contain about 4 grs. antacids, 8 grs. salines, 2 1-10th grs. purgatives; these bring it within the mildest class of ordinary palatable waters, quite distinct from those which must be classed either as purgative or tonic.

The amount of salt present is sufficient to render it palatable and refreshing without requiring an addition as in the case of so many other waters. It is very free from nitrogenous organic matter, and would be classed as a highly pure natural water. We have tried it for some time as a table water and are sufficiently pleased with the experiment to recommend others to do the same. It retains its gas well and has a refreshing flavour even after having been opened for a considerable time. It is a useful palatable digestive water.

Hospital Work in Naples.—The Naples correspondent of the *Standard*, speaking of hospital work in that city, says:—The International Hospital was established six years ago by the combined efforts of the foreign residents in Naples. The British community joined heartily in promoting its foundation, principally on account of the large number of British seamen that come to this port (some 14,000 or 15,000 a year), who, after the English hospital was closed in the year 1874, had, when ill, to be sent to Italian hospitals, where their ignorance of the language and complete isolation made their position most painful. This institution has been a great success, and its prosperity has been further increased by the generosity of Lady Harriet Bentinck, who, by a donation of £4,500, has enabled the trustees to purchase a villa in a beautiful and healthy situation (the present Villa Bentinck), to which the Hospital has been lately removed. The expenditure during the six years and two months that the hospital has been in existence has been 208,944 francs, of which 65,000 were received from patients, and the rest was made up by donations. The total number of patients admitted was 825, 182 being English, and 119 of them gratuitous. Medical advice was afforded gratis to 1,103 persons, of whom 395 were English, and medicines were supplied to them gratuitously. It is contemplated to admit sailors free as indoor patients if they belong to merchant ships whose captains subscribe from five to ten lire on arrival. It is, therefore, essentially a benevolent institution, combined with superior accommodation in private rooms, on moderate terms (6 to 15 francs a day), for those who can afford it, and its existence depends entirely on the generosity of visitors.

Notices to Correspondents.

65 CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a *distinctive signature or initials*, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

LOCAL REPORTS AND NEWS.—Correspondents desirous of drawing attention to these are requested kindly to mark the newspapers when sending them to the Editor.

READING CASES.—Cloth board cases, gilt-lettered, containing 26 strings for holding each volume of the *Medical Press and Circular*, may now be had at either office of this Journal, price 2s. 6d. These cases will be found very useful to keep each weekly number intact, clean, and flat after it has passed through the post.

MR. BAKER.—There is nothing legally against a public analyst holding dual appointments, in fact, any number of appointments, and we know several instances in which from six to eleven such are held by the same officer. We grant you that the Act does not stand the same chance of energetic administration as when the holder has but one district to superintend; especially is this the case when the districts are widely separated, as the public analyst then waits for cases to be brought him, it being scarcely possible for him to go to each town or village to hunt up adulterations himself. However, unless you can prove a dereliction of duty, your protest would have no effect.

F. E. K.—You have no power to enforce payment for your services rendered; although duly qualified, by omitting to register yourself you are debarred from holding a *locus standi* in the County Court. Your plan will be to register forthwith, and then proceed against the defaulter. The book you name is out of date.

DR. CONSTANCE.—Arrangements have been entered into for the publication of the lectures in full; whether they will be subsequently revised in collected form will be for their author to determine.

"MOTHERS' MARKS."

THAT America is a land of wonders there can be no doubt. Last week a correspondent favoured us with a description of the effects of nitro-glycerine lozenges on a patient who had taken them "in America;" they not only moved the patient, but lifted the roof off the hospital, and stuck sundry portions of the attendant nurse in the chimney. This week another correspondent sends us a cutting from an American contemporary as extraordinary evidence of "maternal impressions." A certain woman, Mrs. Adolph Morath by name, who travelled the States on exhibition as "the tattooed woman," gave birth in March last to a boy. Dr. A. Trego Shertzer, of Baltimore, attended the woman, and was very much surprised when he found the babe's skin marked as if with India ink. Upon it were designs of flowers, leaves, an anchor and chain, an eagle, and other figures. A number of doctors of the city have been called in to see the baby, and all have expressed surprise at the curious reproduction of the marks on the mother's skin. What an oversight of Mr. Adolph Morath not to have written his own name on his wife's skin in India ink: the child might then have been born with it, and the parentage would have been undoubted.

L. T.—Your invention reads like a possible improvement; but no certain opinion can be expressed on its merits until a model instrument has been made and tested. You should take steps to have this done without delay.

MR. G. M. H.—We regret the fund has not extended to a larger amount, but even such as it is, is evidence that the world is not altogether destitute of gratitude.

OPENINGS FOR YOUNG SURGEONS IN AUSTRALIA.

OBSERVING frequent inquiries in our columns relative to the Colonies as fields for our over-stocked profession, a correspondent sends us the following information:—

"Although in Sydney there is no lack of experienced medical men, it is otherwise in the remote country districts, and it is not uncommon to come across advertisements in the Sydney papers, notifying the existence of promising openings for doctors willing to rough it for a few years, until the district becomes sufficiently populated to make their position one of a highly lucrative nature. Medical students desirous of emigrating to New South Wales should keep before them the possibility of having to seek their fortunes under such circumstances, which certainly are not severer, although more full of promise, than those which are often found surrounding the early career of medical men in many parts of England."

DR. W. D.—We can make no promises, and are not partial to medical treatises for the masses.

STUDENT.—You do not mention the "Physiology" in which you cannot find an answer to your query. The fluid contains 5 per cent. of solids, with a specific gravity of 1002. You will find this fully described in the two latest works of Thompson, Lowne, and Gerald Yeo.

MR. FRANCIS CAREY.—The specimen consists of a fragment of cusparia bark, *Gaïpez cusparia*, and differs from canella alba in the incurvation of its edges, the bevelling of these, and in possessing a warm aromatic taste. An ounce or ounce and a-half of the infusion may be given.

DR. TAYLOR.—In a matter of the kind named in your letter our judgment would be of little value. You should consult a professional lawyer, who can best advise the right course.

MR. MANTELL asks whether any reader of the *Medical Press* can afford him information respecting the practical results to be obtained by prescribing kairin as an antipyretic? Those who have had experience with this drug may perhaps be willing to state the success or otherwise attending its use, the doses administered, &c., &c.

KAIRIN AS AN ANTI-PYRETIC—A QUERY.

DR. E. E. G.—We prefer not to express an opinion on the subject, especially since the manner in which publicity has been obtained does not, as we conceive, accord with strict and proper views of professional etiquette.

K. K.—An account of suicides committed by lunatics would prove extremely interesting if properly compiled; and we shall be glad to consider the matter further if you persevere in your present intention.

MR. J. SMITH (Cardiff).—No occasion has yet arisen to call forth the remarks you seem to suggest. When it does we shall not hesitate to say all that is necessary.

DR. TALKINGTON.—In such a case the parish medical officer should be informed of the occurrence, and left to act on it.

DR. J. O. C. (Plymouth) is thanked for his communication.

DR. C. F. TAYLOR (Philadelphia).—We cannot further increase our already too large exchange list.

The Societies, College Lectures, &c.

WEDNESDAY, JUNE 18TH.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—At 4 p.m., Sir Henry Thompson, On Some Important Changes in connexion with the Surgery of the Urinary Organs.

HOSPITALS ASSOCIATION (Rooms of the Medical Society of London).—At 8 p.m., Canon Erskine Clarke, "Is it desirable that Hospitals should be made self-supporting, and if so, to what extent?"

FRIDAY, JUNE 20TH.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—At 4 p.m., Sir Henry Thompson, On Some Important Changes in connexion with the Surgery of the Urinary Organs.

Vacancies.

Clogher Union, Clogher Dispensary.—Medical Officer. Salary, £125. Election, June 21.

Dromore West Union, Skreen Dispensary.—Medical Officer. Salary, £130. Election, June 19.

Dudley Dispensary.—Resident Medical Officer. Salary, £130, with house, &c. Applications to the Hon. Sec. before July 1.

Liverpool Dispensaries.—Assistant House Surgeon. Salary, £108, with apartments, &c. Applications to the Secretary by June 24.

Queen's College, Birmingham.—Professorship of Anatomy. Stipend is £262 10s. Applications to the Secretary by June 30.

The County Asylum, near Dorchester.—Assistant Medical Officer. Salary, £100, with furnished house, board, &c. Applications to the Medical Superintendent by June 28.

York County Hospital.—Assistant House Surgeon. Salary, £50, with board and residence. Applications to the Secretary by June 21.

Yorkshire College, Leeds.—Chair of Physiology. Stipend, about £200. Applications to the Secretary by July 2.

Appointments.

ACLAND, T. D., M.B. Oxon., M.R.C.P. Lond., Assistant Physician to the Hospital for Consumption, Brompton.

BEVERLEY, J. M., M.B. Lond., M.R.C.S., Assistant Lecturer on Medical Jurisprudence and Demonstrator on Toxicology, Owens College, Manchester.

CATHCART, W., M.B., F.R.C.S.E., Assistant Physician to the Edinburgh Royal Infirmary.

EVANS, E. R., L.R.C.P. Lond., M.R.C.S., Honorary Surgeon to the Hertford General Infirmary.

FINLAY, T., L.R.C.P. Ed., L.R.C.S.I., Medical Officer for the Greenwood Dispensary District of the Dunfermly Union.

HART, D. B., M.D., F.R.C.P. Ed., Assistant Physician to the Edinburgh Royal Maternity Hospital.

HEARD, C. DE W., M.D., C.M., L.R.C.P. Ed., Medical Officer for the Keelby District of the Caistor Union.

LOVERIDGE, A. W., M.R.C.S., House Surgeon and Secretary to the West Norfolk and Lynn Hospital.

LYON, T. G., M.R.C.S., L.R.C.P., Clinical Assistant in the Skin Department, St. Thomas's Hospital.

MACCULLOCH, A., M.B., C.M. Glas., Medical Officer for the Tarporley District of the Nantwich Union.

NEALE, A. J., M.B., Medical Officer to the Manchester Hospital for Diseases of the Skin.

ORFORD, J., M.R.C.S., L.R.C.P., Resident Accoucheur to St. Thomas's Hospital.

POWELL, J. A., M.B. Dub., L.R.C.S.I., House Surgeon to the Worcester General Infirmary.

RICHARDS, T., M.B. Ed., Assistant Physician, Honorary Physician to the Birmingham and Midland Hospital for Children.

ROBERTSON, T. M., M.B., C.M. Ed., House Surgeon to the Durham County Hospital.

ROWLANDS, H. P., M.R.C.S., Medical Officer for the Towyn District of the Machynlleth Union.

SHELDON, T. S., M.B. Lond., M.R.C.S., Medical Superintendent to the Chester County Asylum.

STOKER, G., M.K.C.P.T., M.R.C.S., Surgeon to the Hospital for Diseases of the Throat and Chest, London W.

SWIFT, H. R.A., M.B. Cantab., Senior Resident Medical Officer to the Hospital for Sick Children, Great Ormond Street.

THOMSON, J., M.B., C.M. Ed., House Surgeon to the Hospital for Sick Children, Great Ormond Street.

UNDERHILL, C. E., M.B., F.R.C.P. Ed., Assistant Physician to the Edinburgh Royal Maternity Hospital.

Births.

ABBOTT.—June 11, at Noel House, Braintree, Essex, the wife of Charles E. Abbott, M.R.C.S., of a son.

Marriages.

DARTNELL—JONES.—June 12, at St. Paul's Church, Liverpool, William A. Dartnell, F.R.C.S., of Rochester, to Isabella Steele, youngest daughter of the late J. J. Jones, of Fontenoy, Liverpool.

FRASER—CHITTY.—June 12, at Christ Church, Clifton, James Alex. Fraser, M.R.C.S., L.R.C.P. Lond., to Helen Alves, eldest daughter of Colonel W. T. Chitty, H.M. Bombay Staff Corps.

Deaths.

BUSH.—June 11, at Glenbourne, near Southampton, Thomas G. Bush, M.R.C.S. and L.S.A., late of Bradford, Wilts, aged 60.

DICKSON.—June 11, at The Albany, Piccadilly, J. Burnie Dickson, Inspector-General of Hospitals, Bengal Medical Service, aged 78.

HAMILTON.—May 31, at Tarbet, William Hamilton, M.D.

STRANGE.—June 2, at Lyonsdown, New Barnet, George Harrison Strange, F.R.C.S. Eng., aged 64.

WODSWORTH.—May 23, at the Royal Naval Hospital, Haslar, Charles Gregory Wodsworth, Staff-Surgeon, R.N.

IRISH POOR-LAW INTELLIGENCE.

THE CIVIL SERVICE SCALE OF IRISH POOR-LAW PENSIONS.

We learn with much satisfaction that the Local Government Board for Ireland has given its sanction to the grant to Dr. Wilson, of Edgeworthstown, co. Longford, of the full pension of two-thirds of his emoluments as Dispensary Medical Officer. Under the Civil Service scale of superannuation which the Board laid down some years since as limiting the amount of pension which they would sanction, Dr. Wilson would have received a much smaller superannuation allowance than that voted to him by the guardians of his Union, but the Local Government Board has, in this particular instance, and, we believe, for the first time since the promulgation of the scale, gone outside its terms, and sanctioned a higher rate of pension.

The circumstances of Dr. Wilson's case were special, inasmuch as he had been permanently disabled from Poor-law work by a compound fracture of his ankle-joint, received when performing his official duty, and he had received the injury some months before the Civil Service scale was adopted by the Local Government Board. If, therefore, Dr. Wilson had applied for superannuation immediately on receiving injury he would have been granted the full pension, inasmuch as his guardians were almost unanimously in his favour, and it would, therefore, have been obviously unjust to limit the amount by a circular issued subsequently.

We think the Local Government Board acted wisely and justly in the matter, and that the Council of the Irish Medical Association was fully justified in departing from usage and using its official influence with the Local Government Board in Dr. Wilson's favour, and we are glad that the principle has been established that the Civil Service scale may be departed from under special circumstances.

Appropriately to the case of Dr. Wilson, we take occasion to say that the limitation of the pensions of Irish Poor-law Medical Officers by the Civil Service scale is, in our opinion, a pure matter of voluntary compliance by boards of guardians and Poor-law medical officers with the order of the Local Government Board, there being no power whatever in that Board or in any

one else to impose any limitation of the amount of superannuation allowance, except the limitation imposed by the Act of Parliament. In other words, the *general* application of the Civil Service scale to all medical officers, irrespective of the individual circumstances of the case, is, in our opinion, totally illegal, and the issue of the circular fixing the Civil Service scale of pension was altogether outside the power of the Local Government Board. The Act which declares this is the 28th Vict., cap. 26, section 1, and it says that "the guardians may, at their discretion, with the consent of the Poor-law Commissioners, grant to any officer . . . who shall become incapable of discharging the duties of his office with efficiency, by reason of permanent infirmity of mind or body, or of old age, upon his resigning or otherwise ceasing to hold his office, an annual allowance not exceeding in any case two-thirds of his then salary." From this it appears that the guardians are empowered to grant a pension up to two-thirds of the salary, but that the Local Government Board may, in the case of any individual officer, and having regard to the circumstances of that particular case, refuse to sanction the grant. They could not, as we believe, either reduce or increase the guardians' vote by a single shilling, and, if they saw fit to refuse their sanction, they would do so subject to the liability to give sufficient reasons in a court of law. For example, if a board of guardians pleased, for personal or political reasons, to grant a pension to an undeserving officer, or one who was liable to dismissal for some offence, or to one who was not really incapacitated from duty, the Local Government Board would have a right to veto the grant absolutely, but they would be liable, in so doing, to be brought into court to show that they did not, in so doing, act arbitrarily or for any other than public reasons.

Their power of veto is, in fact, to be exercised subject to a reasonable interpretation of the Act, and it could not be for a moment maintained that when Parliament gave a general commission to the Board of Guardians to grant a pension amounting to *two-thirds* of the officer's salary, it, at the same time, gave a contrary authority to the Local Government Board to deprive the Guardians of that power, and to decree that, in all cases, the pension should not be more than *one-third*.

The sanctioning power of the Local Government Board is, therefore, in our opinion, applicable to particular cases and for particular reasons, and any general

order limiting pensions without regard to the special circumstances of each case is *ultra vires* and illegal.

While we express this view of the law, we take no exception to the application of the Civil Service scale to the case of Poor-law medical officers, and we have always advised our readers to accept the scale without questioning it at law. We have done so, however, in anticipation of its being given to the officer, not at the discretion of his guardians, but as a matter of right. This is a matter of simple fairness. If the guardians are to have discretion as to grant of pension, let them have it uncontrolled; if the pensions are to be fixed by the Local Government Board, let them be limited and compulsory, for there can be no equity in giving the guardians a discretion downwards and limiting that discretion upwards. It should, therefore, be distinctly understood that, if anything should prevent the Irish Poor-law Superannuation Bill becoming law, the Poor-law medical officers will repudiate the Civil Service scale, and will insist upon the Boards of Guardians being permitted to exercise their right of granting pensions in excess of that scale if they so see fit.

LIST OF ENTRIES IN THE REGISTER OF THE BRANCH MEDICAL COUNCIL (IRELAND) FOR OCTOBER, NOVEMBER, AND DECEMBER (UP TO 22ND INST.) 1883.

OCTOBER 2nd.—Fitzgerald, J. R., 3 Goldsmith Street, Dublin, Lic. R. Coll. Surg. Irel. 1883.
3rd.—Bolster, J., Bahrhay, co. Cork, M.D. and Mast. Surg. R. Univ. Irel. 1883.
4th.—Tobin, T. J., 20 Lombard Street, Waterford, Lic. R. Coll. Surg. Irel. 1878, Lic. R. Coll. Phys. Edin. 1881.
13th.—Freeman, D. W., 6 Drumcondra Road, Dublin, M.B. Univ. Dub. 1882.
16th.—Russell, R. U., Rock Abbey, Cashel, Lic. R. Coll. Surg. Irel. 1883.
16th.—Martin, J. T., Kilroe, Clogheen, Lic. R. Coll. Surg. Irel. 1883, Lic. K. Q. Coll. Phys. Irel. 1883.
17th.—Myles, H. G., Hospital for Incurables, Dublin, L.A.H. Dub. 1880, Lic. R. Coll. Phys. and Surg. Edin. 1883.
18th.—Donnellan, P. S., Mount Kennett, Limerick, Lic. R. Coll. Surg. Irel. 1883.
20th.—Nealon, J. A., Killadysert, co. Clare, M.D. R. Univ. Irel. 1883.
22nd.—Digby, C. A., 42 Wellington Place, Dublin, M.B. and Bach. Surg. Univ. Dub. 1883.
23rd.—Allen, J. P., 180 Great Brunswick Street, Dublin, L.A.H. Dub. 1883.
26th.—Stack, E. C., Monaghan, Lic. R. Coll. Surg. Irel. 1883.
26th.—Swanton, J. H., St. Luke's, Cork, M.D. and Mast. Surg. R. Univ. Irel. 1883.
26th.—Calwell, W., 4 College Square, N., Belfast, M.D. and Mast. Surg. R. Univ. Irel. 1883.
26th.—Brownlee, J. J., Portadown, M.D. R. Univ. Irel. 1883.
26th.—Taylor, H. J., Omagh, M.D. R. Univ. Irel. 1883.
26th.—Taylor, J., Omagh, M.D. R. Univ. Irel. 1883.
26th.—Henderson, R. W., Garvagh, M.D. and Mast. Surg. R. Univ. Irel. 1883.
26th.—Gausson, P. P., Holly wood, co. Down, M.D. R. Univ. Irel. 1883.
27th.—McMahon, J., Wellington Road, Cork, M.D. and Mast. Surg. R. Univ. Irel. 1883, Lic. Mid. K. Q. Coll. Phys. Irel. 1883.
27th.—McAlister, W. R. A., Lurgan, M.D. and Mast. Surg. R. Univ. Irel. 1883.

29th.—Somers, J. L. E., Roscrea, Lic. R. Coll. Surg. Irel. 1883, L.A.H. Dub. 1883.

NOVEMBER 1st.—Lindsay, A., Ramilton, M.D. R. Univ. Irel. 1883.

1st.—Brown, G., Newport, Tipperary, Lic. R. Coll. Phys. and Surg. Edin. 1883.

1st.—Massey, H., Portrush, M.D. R. Univ. Irel. 1883.

2nd.—Henderson, J., Glenties, Armagh, M.B. and Mast. Surg. Univ. Edin. 1883.

2nd.—Byrne, J. V., Drogheda, Lic. R. Coll. Surg. Irel. 1883, L.A.H. Dub. 1883.

2nd.—Franklin, T. E., Upper Garville Avenue, Rathgar, Lic. R. Coll. Phys. and Surg. Edin. 1883.

3rd.—Russell, B. T., Borris-o-Rane, Lic. R. Coll. Surg. Irel. 1883, Lic. K. Q. Coll. Phys. Irel. 1883.

3rd.—Dwyer, T. C., 4 Great Denmark Street, Dublin, M.B. and Bach. Surg. Univ. Dub. 1883.

6th.—Woods, C. G., Glen Distillery, Cork, M.D. and Mast. Surg. R. Univ. Irel. 1883.

6th.—Ryan, J. F., Loughrea, Lic. R. Coll. Phys. and Surg. Edin. 1883.

6th.—McHugh, M., 56 Northumberland Road, Dublin, M.B. Univ. Dub. 1882, Lic. R. Coll. Surg. Irel. 1882.

7th.—Ellison, J., Lisburn, M.D. R. Univ. Irel. 1883.

7th.—Hartigan, T. J. P., Templemore, Lic. R. Coll. Phys. and Surg. Edin. 1883.

8th.—Kelly, R. E., St. Luke's, Cork, M.D. and Mast. Surg. R. Univ. Irel. 1883.

9th.—Simpson, J., Cullyhaskey, co. Antrim, M.D. Q. Univ. Irel. 1881.

13th.—Hall, T. G. H., Belturbet, Lic. R. Coll. Surg. Irel. 1883, Lic. and Lic. Mid. K. Q. Coll. Phys. Irel. 1883.

14th.—Hood, J. C., Lifford, M.D. R. Univ. Irel. 1883.

16th.—D'Arcy, R. J., 2 Adelaide Road, Kingstown, Lic. R. Coll. Surg. Irel. 1883, Lic. and Lic. Mid. K. Q. Coll. Phys. Irel. 1883.

16th.—Meek, J., 52 Agnes Street, Belfast, M.D. and Mast. Surg. R. Univ. Irel. 1883.

20th.—Nepean, E. St. M., Lic. R. Coll. Phys. Edin. 1883, Lic. Fac. Phys. Surg. Glas. 1883.

20th.—Robinson, W. H. B., 20 Waterloo Road, Dublin, Lic. R. Coll. Surg. Irel. 1883.

20th.—Fagan, C. J., 43 Booterstown Avenue, Blackrock, M.B. and Bach. Surg. Univ. Dub. 1883.

21st.—Fallon, J., Athlone, Lic. R. Coll. Phys. and Surg. Edin. 1883, L.A.H. Dub. 1883.

22nd.—O'Connell, J., Rathkea, Tipperary, M.D. R. Univ. Irel. 1883.

MOUNTMELICK UNION.

MEDICAL OFFICERS AND THE GUARDIANS.

A LETTER was read from Dr. Hanlon requesting payment of £6 6s. due to him for acting as *locum tenens* for two weeks during the illness of Dr. Tabuteau, medical officer of the Cloneygowan dispensary district.

Mr. Cobbe objected to paying Dr. Hanlon, on the grounds that the dispensary committee had failed to comply with the regulations. They were bound when the medical officer reported that he was incapacitated from discharging his duties to appoint a substitute, and the board of guardians then fixed the rate of remuneration. But the committee failed to appoint any substitute until Dr. Hanlon had acted for some time. An excessive salary was paid to the medical officer for Cloneygowan. He could well understand the case if the committee were able to report that the medical officer had contracted illness in the discharge of his duties.

In reply to Colonel Carden, the Chairman said a meeting of the dispensary committee had been convened for the purpose of appointing a substitute.

Mr. Atkinson reminded the board that they were the guardians of the poor as well as the guardians of the ratepayers' money, and if they refused to pay Dr. Tabuteau's substitute, what would be the probable effect? If a medical officer became ill he could not discharge his duties, and if there was no medical gentleman willing to discharge them for him on the faith that the board would remunerate him, the poor would be neglected.

In reply to Colonel Carden, the Chairman said that Dr. Hanlon's appointment appeared to have been made on the 14th inst., but Dr. Hanlon commenced his duty on the 3rd instant.

Colonel Carden—It strikes me it is very hard if through the negligence of a dispensary committee either the poor are to suffer or the medical officer's substitute is not to be paid. Supposing there was not time to summon a committee what would happen? Surely there ought to be some honourable feeling that if a doctor discharges duties he should be paid for them.

Mr. Cullen said that of late the ratepayers had been passing through great trials, and the landlords had to submit to a reduction of 25 per cent. off their rents, and every man in business had to reduce his charges, and the income of the farmers was more than 25 per cent. less than it was. But in the good times medical men had been granted 25 per cent. of an increase to their salaries, and if it was necessary for the board to pay substitutes for the medical officers, he thought the board ought to lower the medical officers' salaries 25 per cent. He would move that they should pay the substitutes at present, and then that they should reduce the medical officers' salaries.

Mr. Cobbe—You cannot do that; the Local Government Board will not sanction it.

Mr. Cullen—Then we will petition Parliament to abolish the Local Government Board (laughter).

Mr. Pattison concurred in the view that if the guardians did not now pay Dr. Hanlon the poor would be likely to suffer in the future, through the unwillingness of any doctor to discharge the duties of any medical officer who might be incapacitated from discharging his duties.

Mr. Cobbe, after some further discussion proposed a resolution to the effect that the guardians declined to pay Dr. Hanlon.

Mr. Atkinson proposed an amendment to the effect that it would be injurious to the interests of the poor to refuse to pay Dr. Hanlon, and that the Local Government Board should therefore be requested to sanction the payment. He said the question was ought the board to act in such a manner that they would not be trusted in future to pay a substitute, in case of the illness of a medical officer? He was astonished to hear Mr. Keating opposing the payment. Last week, Mr. Keating dwelt at considerable length on the hardship the poor would suffer if the guardians did not pay a medical officer's substitute.

Mr. Bailey having seconded Mr. Atkinson's resolution, a division was taken with the following result:—For the resolution, 18. For the amendment, 5.

The resolution was therefore declared carried.

Colonel Carden—After that resolution medical gentlemen should get notice that on the next occasion in which a medical officer in this union gets ill, they will not be paid for acting as substitute.

Mr. Cobbe—I think that would be most improper notice, because the medical officers are all well able to pay their substitutes themselves.

Colonel Carden—There is nothing like putting the matter before them in a fair way.

Dr. Jacob—There has been a vast amount of gratuitous medical service rendered to the public in the Queen's county that the guardians know nothing about. It is only in long serious matters that it comes before the board at all.

The subject was not discussed further.

The Clerk read a letter from the Local Government Board stating that they would not raise any objection to the remuneration at the rate of 10s. 6d. a day proposed to be paid to Dr. Hanrahan as *locum tenens* for Dr. Fisher while the latter was attending the Kilkenny Assizes as a Crown witness. The Clerk also read an application from Dr. Hanrahan for £3 13s. 6d. for discharging Dr. Fisher's duty. The application was duly certified by the chairman of the dispensary committee, and no objection was made to the application.

A letter was read from the Local Government Board sanctioning the payment of £8 8s. to Dr. Rice for two weeks' service as temporary medical officer to the workhouse and Mountmellick dispensary, while Dr. Neale was incapacitated from performing his duties by an accident.

The clerk was directed to draw a cheque in Dr. Rice's favour for the amount.

The Clerk said that the guardian had passed a resolution to deduct £2 from Dr. Neale's salary as a contribution towards the payment of Dr. Rice. He had mentioned the fact to Dr. Neale who declined to agree to any deduction from his salary.

Mr. W. H. Cobbe—Well let him produce for the amount of his salary, and I will produce witnesses.

The Chairman—The question is, will the clerk fill a cheque for the full amount of Dr. Neale's salary?

Mr. Cobb—I say certainly not. Dr. Neale got notice that the £2 would be deducted from his salary, if he was not able to resume his duties at the end of a certain time.

Colonel Carden—The payment of Dr. Rice out of the rates has been sanctioned by the Local Government Board, and if Dr. Neale insists upon his rights, which of course he will, it is only throwing away money to resist.

Mr. Cobbe—The payment of Dr. Rice is sanctioned on conditions.

Colonel Carden—What conditions?

Mr. Cobbe—That Dr. Neale would pay his substitute

for one week, and it is time to bring these gentlemen to bay.

At the request of the chairman, the clerk read the resolution respecting the deduction of the £2 from Dr. Neale's salary. It was as follows ;—

"That Dr. Neale's application be granted for one week's further extension on the following terms :—£2 to be paid to his substitute for the workhouse, and the same to be deducted from his salary ; and that the payment for the dispensary be allowed."

Colonel Carden—Did Dr. Neale agree to those terms ?

The Clerk—He did not.

Mr. Cobbe—He did not dissent, and he got a week's notice.

Colonel Carden—It is only throwing money away to resist paying him his full salary.

Mr. Gallagher—Can the doctor ignore us ?

Colonel Carden—He can ignore you in this case.

Mr. Cobbe—Then we will call on him to resign, and I will show the country what is going on. Mr. Cobbe then moved that the £2 be stopped from Dr. Neale's salary.

Mr. Keating seconded the proposal.

Colonel Carden moved a direct negative, and said that Mr. Cobbe's proposal was quite illegal. It came to this : could the board stop any amount they liked from the medical officer's salary ?

A division was taken with the following result :—For Mr. Cobbe's motion, 17. Against, 5.

Mr. Cobbe's motion was accordingly declared carried.

BALLINA UNION.

DR. SCOTT'S REPORT

Dr. Scott reported that on the requisition of the sub-sanitary officer he had inspected Mr Malone's store in Shambles Street, which he found in a sanitary state save so far as the presence of rags in a place might render it insanitary. The board should consider whether it was proper to allow a rag store in a populous portion of the town.

Mr. Mooney.—It was reported that herrings and bacon were kept there.

Dr. Scott.—I visited the store on several occasions, and I consider it is kept very well. It is a question whether the sanitary authority will allow a rag store at all there.

Mr. M'Nulty.—You would advise its removal ?

Dr. Scott.—I don't consider it a fit place for a rag store.

Mr. M'Nulty.—Then you condemn it ?

Dr. Scott.—Only so far as it is a rag store.

Chairman.—Then the rags must be removed.

Mr. M'Nulty.—And if from there then from every other public place.

Dr. Scott.—The question is, have you the power.

Mr. M'Nulty thought the doctor might act on his own authority.

Dr. Scott said that it was for the board to direct.

Mr. M'Nulty.—What do you advise ?

Dr. Scott.—I have given you my opinion. Consult Dr. Macaulay, your consulting sanitary officer.

Mr. M'Nulty.—You can have his opinion.

Dr. Scott.—No. He is to give you his opinion. It is his duty.

Mr. Colman.—The board have a right to ask Dr. Macaulay.

Dr. Scott.—He is to be consulted where there is a difficult question.

Dr. Macaulay.—I have not seen the place at all. I would first clean the street.

Dr. Scott.—I would say so, too.

The subject then dropped.

THE FEVER HOSPITAL.

Dr. Macaulay reported that four fresh cases of typhoid

fever had been admitted to hospital during the week ; two were discharged cured ; there were no deaths, and 23 remained under treatment. He urged the necessity of appointing two extra paid nurses without further delay. The patients with the present staff of nurses were more or less neglected. He also requested that steps be taken to have the fever wards lime washed.

Master.—It is impossible to get it done by pauper labour.

Chairman.—The paupers should be got to do it.

Master.—You have to give them such a lot of extras that the other would be cheaper.

Mr. Daly.—You have a number of abled bodied young men in the house. I saw them the other day driving a cart, and if they don't do what you tell them you can compel them, or else turn them out the gate.

Master.—I don't think you have power to compel them.

Mr. M'Nulty.—Well, induce them.

Dr. Macaulay.—We have offered them frequently any amount of extras.

Chairman.—If it cannot be done from within the house, employ a lime-washer.

This was approved of.

Dr. Macaulay.—You must now appoint nurses, as the fever patients are being neglected. I have at present a woman whom I would not keep if I had any choice. It is a false economy to try and induce paupers to act by giving them extras which come to some £13 or £14 a year.

Clerk.—The persons you appoint and pay will get officers' rations.

Chairman.—We leave the matter in the doctor's hands for the present.

Mr. M'Nulty.—Whatever we pay we must get proper nurses.

Dr. Macaulay.—If you leave it with me I will get a nurse in town, but will have to pay her £1 per week, as you will not get a competent nurse for less.

Chairman.—If you must have the nurses, and that you will have to pay £1 a week, it seems there is no alternative.

Dr. Macaulay.—I have been told that the present nurses won't get up at night to wet the patients' lips. There is night as well as day work.

Chairman.—We will allow you to use your own discretion until this day week.

THE HEALTH OF DUBLIN.

ACCORDING to the report on the state of public health in Dublin during the four weeks ended 1st December, 1883, just issued by Dr. Cameron, Superintendent Medical Officer of Health, the deaths within the metropolitan registration area were in the ratio of 27.32 per 1,000 persons living. Within the municipal area they were in the annual ratio of 29.42. The deaths from the seven principal zymotics were 3.42 per 1,000 persons. As compared with the preceding month, there was a slight decrease in the mortality caused by scarlet fever, and a large decrease in the number of deaths due to diarrhoea and dysentery. There were very few deaths from the other zymotic diseases in either month. As compared with October, there were large increases in the admissions of patients into hospitals, affected with scarlet, typhus, and typhoid fever. It is to be feared that these facts presage a high mortality during the ensuing month.

The death-rate in the city, which was 27.44 per 1,000 persons living, in October, rose to 24.92 per 1,000 in November. As compared with the November of 1882, there was an increase of 2.02 per 1,000, and of 1.74 per 1,000 as compared with 1881. There, was however, a decrease of 7.13 per 1,000 as compared with November, 1880.

Only one zymotic disease was rife during the month—that was scarlet fever, which has been epidemic for some months past. In October (five weeks), this disease killed 48 persons ; in November, 33 persons fell victims to it.

IRISH POOR-LAW INTELLIGENCE.

LIST OF ENTRIES IN THE REGISTER OF THE BRANCH MEDICAL COUNCIL (IRELAND) FOR JANUARY, FEBRUARY, AND MARCH, 1884.

JANUARY 4th.—Morris, A. E., Edenderry, M.D. R. Univ. Irel. 1883, Mast. Surg. R. Univ. Irel. 1883.
5th.—Jackson, J. B., Rathvilly, M.D. R. Univ. Irel. 1883, Mast. Surg. R. Univ. Irel. 1883.

Newry Borough—Mr. P. J. Kelly.
Waterford Borough—Messrs. G. J. Mackesy, J. F. Scott.

(W) stands for union medical officer.
 (D) stands for dispensary medical officer.

CORRESPONDENCE.

FRAUDS ON DISPENSARY MEDICAL OFFICERS.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—Will you kindly instruct me in the case I am about to put to you? I am a dispensary medical officer, and a man in my district, who has fee-simple property, and a large farm besides, gets a visiting ticket to attend his son. A medical friend acting for me at the time, without knowing what position this man held, attended the patient. I got this ticket cancelled by the Dispensary Committee. I was on sick leave and came back to my district before my leave was expired. This person again got a visiting ticket for me. I sent back the ticket saying, I am not bound to attend this ticket as another doctor 12 or 14 miles away is paid to discharge my duties. Now this man is determined to get me if possible to attend on a visiting ticket. The plea he puts forward is that he has provided for his son, having sent him into business as an assistant in a shop, and that he has come home to his father's house for the good of his health. I am quite certain the father will get a *third* visiting ticket for me, because he has a brother and two nephews on my Dispensary Committee. In the event of his doing so, will you please inform me if I have a chance of recovering any fees from him legally when I get the third ticket cancelled? If you say I have I will willingly spend more than half of a quarter's salary in endeavouring to get fees from this man who is wealthy, but who has lost all shame in this locality when he does a thing of the kind I have mentioned.

I am, Sir, &c.,

A YOUNG PRACTITIONER.

[If you receive a ticket you must attend on it, but, when it has been cancelled, you can sue either the recipient of the ticket or the person who issued it. If the latter, you must be prepared to show that he had means of knowing that the recipient was able to pay. Whether the father or son are liable to you, will depend on whether the son is of full age or not. The father, though admittedly wealthy, could not be made to pay for an attendance on his son unless the son is under age, or unless he (the father) retained your services. Whatever your own rights may be, belong also to your *locum tenens*. We shall be glad to advise you further if desired.—ED.]

QUEEN'S COUNTY QUARTER SESSIONS.

Before J. CLARKE, Q.C.

IMPORTANT TO POOR-LAW MEDICAL OFFICERS.

DR. HANLON v. THE MOUNTMELICK BOARD OF GUARDIANS.

THIS was an action to recover the sum of £6 6s. remuneration alleged to be due by the defendants to the plaintiff for having acted for a fortnight as temporary medical officer of the Cloneygowan dispensary district.

Mr. Roe (acting for Mr. Clifford Lloyd, solicitor for the Irish Medical Association), appeared for the plaintiff; Messrs. T. and H. Turpin appeared for defendants.

Mr. Roe, in moving the process, said—This is an action brought by Dr. Hanlon, of Portarlinton, against the guardians of the Mountmellick union for the recovery of £6 6s. for fees due for medical attendance in connection with the Cloneygowan dispensary in the union of Mountmellick. Of that dispensary Dr. Tabuteau is the medical officer, and he being struck down suddenly by illness, the dispensary committee, in pursuance of the powers vested in them under act of parliament, and the orders of the Local Government Board, appointed Dr. Hanlon as a *locum tenens* for Dr. Tabuteau, so that the wants of the poor might be attended to. The time of the attendance was one fortnight, and the sum charged was the ordinary thing for temporary services. Dr. Hanlon was a highly respectable medical practitioner, and, fortunately perhaps for himself, he was not dependent on the Mountmellick board of Guardians. But at all events he gave his attendance in pursuance of the powers vested in the committee, and why he is not paid I am puzzled to know, and why it is a certain portion of guardians, who call themselves "Nationalists"—

Mr. H. Turpin—Don't import those things.

Mr. Roe—It is a noisy section of the guardians opposes the payment of these £6 6s. for the services rendered to the sick poor of the district. The month previous, I am instructed, the guardians paid two other gentlemen in the union who filled the same position as Dr. Hanlon, without murmur or complaint. Perhaps these two gentlemen were more in concord with their feelings, but Dr. Hanlon and Dr. Tabuteau not being of the same stuff, and their mode of thought being different, they resisted paying these £6 6s. The dispensary committee passed the resolution that Dr. Hanlon should act as substitute for Dr. Tabuteau, and none of the committee were against it. I have only to say that if every doctor who is brought in this way for a temporary purpose is resisted in this way, it will be very difficult to get any medical gentleman to give his services. I will call Dr. Hanlon and Mr. Phillips, the chairman of the dispensary committee, and there is no more kind-hearted man, and no man more anxious to look after the interests of the poor.

Dr. Hanlon, the plaintiff, swore that in the beginning of December, he was called in by Dr. Tabuteau, who is medical officer of the Cloneygowan dispensary district. Dr. Tabuteau was ill, and unable to attend to his duties as medical officer. Witness discharged the duties of medical officer from the 3rd to the 17th December. Witness had acted as *locum tenens* occasionally during the last thirty years, and was paid by the guardians.

Cross examined by Mr. Turpin—I was called in about the 2nd or 3rd December.

Mr. H. Turpin—Do you know if Dr. Tabuteau gave notice to the dispensary committee?

Witness—He was not capable of doing so. He was suffering from inflammation of the throat, which ended in abscess. He was unable to write a letter.

Could he get no one to write for him? I cannot say that. Dr. Tabuteau did not go to Dublin while I was attending the dispensary.

Don't you know that he went to attend an operation which was being performed on a friend of his? I don't know anything of the sort. He did not leave the house from the time I commenced to attend him. He was confined to bed for about six or seven days. I acted for Dr. Tabuteau while he was suffering from scarlatina. I have been in the habit of performing his duties when he was a day absent.

And he used to pay you himself? No.

Do you swear that? Whenever I was appointed *locum tenens*, I was paid by the board.

When did you receive an official notification that you were appointed *locum tenens*? I think about the 10th or 12th of December.

And you were acting from the 3rd December to the 12th without being appointed by the committee?

Mr. Roe—I don't know any power in the board of guardians to revise the action of the dispensary committee.

Mr. Turpin—Is it not the habit of the dispensary committee to recommend payment of your remuneration to the board of guardians, and is it not on that they act?

Witness—I was never questioned before.

Did you not act on the faith of Dr. Tabuteau paying you himself? No.

But you received no directions from the dispensary committee from the 3rd December to the 12th? No.

Mr. William Phillips, J.P., Chairman of the dispensary committee, produced the minutes of a special meeting of the committee held on the 12th December, appointing Dr. Hanlon as *locum tenens* during Dr. Tabuteau's illness.

In answer to Mr. Turpin, witness said he received a letter from Dr. Tabuteau stating he was ill on the 9th instant, and he at once convened a meeting for the 12th instant.

His Worship—Mr. Turpin, surely this is a matter of common Christian charity. It is a matter of common Christian duty, and there ought not to be any point raised about it. I am sure you are the last man who would do such a thing, because I believe you are a thorough gentleman in every sense of the word.

Mr. Turpin—I am obliged to rely on the legal position of the guardians.

Mr. Phillips—It was insinuated that Dr. Tabuteau was well enough to attend his mother-in-law's funeral; but that is not the case. Dr. Tabuteau was not able to attend.

Dr. Tabuteau—I was not away at all.

Mr. Turpin—My case is shortly this, and though your Worship may think it a case that ought not to be insisted on, I don't think, your Worship, when you hear the article of the Local Government Board's regulation bearing on the case, you will think it such a hardship. Dr. Tabuteau took his appointment under the rules relating to the Poor Law Acts. He was well aware of the restrictions to which he was subject. The 22nd Article provides: "If a medical officer of the dispensary district be temporarily incapacitated by illness, or other cause, from performing his duties, he shall immediately, if practicable, communicate with the chairman or hon. secretary of the dispensary committee, and shall recommend to the committee a medical practitioner qualified, as hereinbefore provided, to perform his duties during his temporary incapacity; and on the fact of the medical officer's incapacity becoming known, a special meeting of the dispensary committee shall be at once called for the purpose of appointing a temporary medical officer, and the committee shall report the circumstances of the case to the board of guardians, who shall, subject to the approval of the commissioners, determine the amount of remuneration, if any, to be paid to the temporary substitute." Dr. Tabuteau, according to the evidence we have heard to-day, was

rendered unable to perform his duties on the 3rd December, and there was no satisfactory evidence that some one on Dr. Tabuteau's behalf could not have sent notice to the committee informing them of his illness, on the 3rd or 4th December. But Mr. Phillips has told your worship he got no notice until the 7th December. I submit that the dispensary committee had no power, under the circumstances, to provide for the appointment during the period that intervened between the 3rd and 12th December. There is really no hardship on Dr. Hanlon, because Dr. Tabuteau is very well able to pay him. Dr. Tabuteau is medical officer of the dispensary district, and draws £160 a year. There is nothing whatever entitles your Worship to grant a decree against the guardians, because the guardians are not bound to grant any remuneration. But I dare say the guardians will pay his £2 2s. as remuneration for the period from the date of the meeting of the committee (the 12th December) and the 17th December.

Mr. Richard Goodbody, clerk of the Mountmellick union, produced the minutes of the guardians' meetings at which the board refused to pay Dr. Hanlon. It appeared that at these meetings amendments were proposed to the effect that Dr. Hanlon should be paid the full amount of his claim, but the resolutions refusing payment were carried by a majority.

Mr. Roe—Do you know whether a substitute for Dr. Higgins was paid a month before?

Witness—He was, but under different circumstances Dr. Higgins had resigned.

Mr. Roe said there was no question that the services for which the claims was made were rendered, and properly rendered. If the medical officer of a district is temporarily incapacitated by illness of performing his duties, it was provided by the regulations that he should give immediate notice to the committee "if practicable," but however that might be, he submitted that the guardians had no power to review the action of the dispensary committee. Dr. Tabuteau was incapacitated by reason of serious illness from discharging his duties, and as soon as he was able to communicate with the committee. If the Article of the Regulations were carried out in a manner that Mr. Turpin contended it should be, when a dispensary medical officer got ill a district would be left without a doctor until a meeting of the committee had been called and its proceedings had been approved of by the board of guardians.

Mr. Turpin—We make a fair offer of £2 2s, and it ought to be adopted. Dr. Tabuteau is drawing a salary of £160 a year.

His Worship made a decree for £6 6s., the full amount claimed by the plaintiff with costs.

INFECTIOUS DISEASES IN NATIONAL SCHOOLS.

TO THE EDITOR.

SIR,—I beg to enclose you herewith copies of letters received by me from the Secretary to the Board of National Education; also a copy of a letter which I have forwarded to Dr. Newell. Should you consider the matter of sufficient interest, will you kindly allow them space?

Yours, &c,

JOHN MOLONY,
Physician and Surgeon, &c.

Collooney, April 7th, 1884.

(COPY.)

Office of National Education, Dublin,
3rd April, 1884.

SIR,—I had the honour to submit your printed letter of the 14th ult., together with an attached memorial, received in this office on the 25th ult., to the Commissioners of National Education, at their meeting on Tuesday last. The memorial is signed by seventeen

medical officers of health, and was adopted at a meeting of the Tubbercurry Poor-law guardians under the presidency of J. W. Armstrong, Esq., D.L. It refers to the consequences arising from the spread of infectious diseases to which children are peculiarly liable, and, after dealing carefully with these evils, closes with the following suggestion :—

“When any disease of an infectious nature is likely to become epidemic and endangers life, and the medical officer of health recommends the closing of the schools in his district to the sanitary authority, that the Commissioners of Education be requested to take into consideration the pecuniary loss which shall be sustained by the school teachers, whose salary is largely dependent on the average daily attendance of pupils at such schools and on the results of the examinations.”

I am directed in reply to state that the Commissioners have, in the case of any National school closed on the certificate of a sanitary officer, always treated the teaching staff with the utmost consideration compatible with their rules. While the school is necessarily inoperative the Commissioners continue salary in full to each teacher, and, when necessary, they sanction the postponement of the results examination to some subsequent period of the year—an arrangement which is found to be satisfactory to both teachers and managers. But under no circumstances can result fees be awarded except on the answering of pupils actually examined.

I am, Sir, &c.,

WM. H. NEWELL, Secretary.

John Molony, Esq., M.D., Collooney.

(COPY.)

Office of National Education, Dublin,

4th April, 1884.

SIR,—I have to acknowledge the receipt of your letter of 31st ult., informing the Commissioners of National Education that the memorial already dealt with by them was approved of by the sanitary authorities of the Boyle, Sligo, and Carrick-on-Shannon Poor-law Unions.

I am, Sir, &c.,

WM. H. NEWELL, Secretary.

John Molony, Esq., M.D., Collooney.

(COPY.)

Collooney, Co. Sligo, April 7th, 1884.

SIR,—I beg to acknowledge the receipt of your letters of the 3rd and 4th of this month.

The object of the memorial which I had the honour of forwarding to you was to prevent, if possible, the attendance at schools of children from infected homes, and also that the Commissioners of National Education might be graciously pleased to take some steps which would interest the teachers in keeping their schools free from infection, that they may by their vigilance co-operate with the medical officers in the protection of public health.

If the State support schools for the education of children, I respectfully submit there should be some guarantee given to parents that the lives of their children while attending as pupils will not be endangered by exposure to infection owing to the neglect of proper precautions either on the part of the teachers or through the “recklessness of parents.” If, under the Contagious Diseases (Animals) Act, railway and shipping companies, market corporations, and private individuals, are obliged to take such stringent precautions to prevent epidemics spreading amongst cattle, is it too much to expect some effort will be made to protect the lives of children who attend schools from healthy homes?

There is, no doubt, a section in the Public Health (Ireland) Act, under which a parent can be punished by fine for sending a child to school within a certain period after an infectious illness without a certificate from a medical practitioner; but I maintain that precaution alone is “lame and impotent,” for, who is sufficiently

interested to see that a parent does not transgress the law? It would be impossible for a medical officer of health and his one subordinate (under the present system) to watch individual cases, and all the schools in a rural district several miles in extent.

The payment of class salaries to teachers while the school is inoperative, and the postponement of result examinations, do not fully meet the case. For the fact still remains patent that deaths are constantly occurring amongst children from diseases contracted at National schools.

If even a similar allowance were granted to the teachers, as is the case during the compulsory closing when Parliamentary and coroners' elections occur, it might possibly assist the object of the memorial.

Until some system of medical inspection of schools is established, and the school teachers are required to report to the medical inspector whenever they become aware of an outbreak of infectious disease dangerous to life either in the vicinity of the school or the homes of their pupils, the public health will suffer and human lives will be lost.

Yours, &c.,

JOHN MOLONY,

Physician and Surgeon, Medical Officer
of Health, &c.

SOUTH DUBLIN UNION.

THE DISPENSARY DRUG LIST.

AT the last meeting of the guardians a letter from the Local Government Board stated that they had before them a minute of the board of the 27th requesting their sanction to a payment of £5 to Mr. Harvey, the apothecary of the house, as remuneration for preparing a revised list of medicines. In reference thereto, the board stated that the list of medicines recommended by them had been prepared with much care, and was sufficient to meet the reasonable requirements of the medical officers. Paragraph 2 of the list stated that in the event of the medical officers requiring to be supplied with any medicine not comprised in the list, a distinct requisition for the same should be made by him to the Committee of Management, stating the circumstances under which he considered it necessary. Any payment made for the preparation of the list of extras would, it was stated, be disallowed by the auditor.

Sir George Owens objected to extra remuneration being allowed to officers who were already well paid. The medical staff now cost nearly double what it did some years ago.

Mr. Crowe mentioned that an article outside the Local Government Board's list which was required by the medical officer of Donnybrook was lately supplied by the contractor at a charge of 18s., whereas it could be bought in the city for 9s.

The Clerk stated that the Local Government Board's list contains 297 items, whereas the list which had been prepared for the guardians contained 488.

Mr. Shackleton moved—

“That, in considering the letter of the Local Government Board in reference to tenders for medicines, the board having ascertained that the list of medicines recommended by the Local Government Board comprises 191 items less than the list of articles which their medical officers required, and have altered in past years, are of opinion that due regard to economy in the expenditure of the rates, and also to the supply of medical requisites, immediately necessitates a tender being prepared for the full list as adopted by the guardians; and they would urge the Local Government Board to sanction the payment of £5 for the preparation of the additions to the list.”

Mr. Byrne seconded the resolution, which was agreed to.

IRISH POOR-LAW INTELLIGENCE.

IRISH MEDICAL ASSOCIATION.

REPORT OF PROCEEDINGS.

From 20th November, 1883, to 15th April, 1884.

(Adopted at Ordinary Meeting of the Council, held 15th April, 1884).

MR. WILLIAM THOMSON, Chairman of Council,
in the Chair.

MR. CHAIRMAN AND COUNCILLORS.—The last ordinary meeting of the Council on 20th November, 1883, was adjourned to 27th November, and further adjourned to the 4th December, 1883, with a view to afford the provincial members of Council full opportunities of discussing the matters referred to in the report, especially the proposition to form branches of the Association. On the 4th December the report was adopted, and it was soon afterwards circulated amongst the members. By direction of the Council a plebiscite was taken on the desirability or otherwise of forming branches, and the Council held a special meeting on the 12th February, 1884, when the *ad interim* report submitted was adopted and ordered to be circulated. Advantage was taken of that opportunity to give the Association further information regarding (1) the prospects of the Union Officers' Superannuation Bill; (2) the action of the Council relative to the claims of Dispensary Medical Officers for their services in connection with the improvement of labourers' dwellings under the new Act; and (3) the steps taken to render the authorities and not a Prison Surgeon liable for remuneration of his substitute when absent on official business; and these matters also were referred to in that report. Since the 20th November, 1883, the Committee of Council have held one special and sixteen ordinary meetings. Twenty-five new members have been enrolled, and one resignation has been accepted.

UNION OFFICERS' SUPERANNUATION BILL.

The Committee regret to report that since date of last report, no satisfactory progress has been made with the Poor-law Officers' Superannuation Bill. When in London on the business of the Association, the President had communications with Mr. H. Gladstone and Mr. Meldon, M.P., as to the prospects of the Bill. He then ascertained, on the authority of Mr. Leahy, M.P., that the Irish party had had the Bill under their consideration and had all agreed—save Mr. Biggar—not to oppose a Bill which would leave the granting of pensions discretionary with the guardians, but subject to an appeal to the Local Government Board. The President ascertained from Mr. H. Gladstone that the Government Bill—in the same form as last year—was being drafted, and that it was intended to introduce it into the House of Lords through Lord Carlingford. Having mentioned to him the proposal made by Mr. Leahy, the President

informed him that the Association would not, on any account, entertain such a proposition as long as they had reasonable hope that the Government Bill would be passed, and an earnest effort made to pass it, that, as regards Mr. Leahy's proposition, the *bona fides* of it might be tested at a future period by causing a private Bill on its lines to be introduced to the Commons. If, on consideration, we thought it inevitable to accept such a proposition which, however, as at present advised, the Association certainly would not do.

The Committee regret that the prospects of domestic legislation of this class seems most discouraging. No Irish bill promoted by Government has, as yet, made any progress whatever, and it does not seem probable that there will be time or opportunity for the discussion of any measure, opposed as this Bill will be, by an influential party. The Committee is anxiously watching for a favourable opportunity to press the Superannuation Bill upon the notice of the Chief Secretary, but is, under existing circumstances, powerless to advance the measure.

THE MEDICAL BILL.

Since the date of last Report your Committee have most anxiously considered the prospects of the Medical Bill, and its most earnest efforts have been devoted to obtain such amendments in the measure as might make it acceptable to the profession and efficient as a measure of reform. In the hope of inducing the Government to introduce these alterations into the Bill before bringing it into the House of Lords, the Committee requested the President, Dr. Jacob, to proceed to London and submit them to the Lord President of the Privy Council. The amendments urged upon the attention of Government were as follows:—

- (a) That the State Examiner should be attached to a Licensing body, during his period of study, and that this affiliation should be necessary to registration.
- (b) That the curriculum and period of study should be uniform throughout the kingdom.
- (c) That the Direct Representative and the Crown Nominee should have seats on the Divisional Board for each division of the kingdom.
- (d) That University Matriculants should only be admitted to the Final Examination at a low fee, if they had fulfilled, at least, three years' study in Arts.
- (e) That the surplus funds in the hands of the Medical Council and Divisional Board should be divided between the licensing bodies in proportion to the educational and examination work done by them.
- (f) That the representation of the Irish College of Physicians on the Divisional Board should be increased.

These propositions were submitted to Lord Carlingford and Mr. Lennox Peel by the President, and were received with attentive consideration. It was, however, explained by the Lord President that the Government did not wish to submit any proposals to the House of Lords other than those which were adopted by them last year, and that the amendments suggested should be urged when the Bill had reached the House of Commons. Accordingly, the Bill was introduced to the Upper House almost exactly in the same form as that in which it left the House last year. It has since then passed the Lords and been read a first time in the Commons, the only changes in the measure being—(1) An increase of the Scotch Corporation representation on the Divisional Board, from 3 to 5; (2) A similar increase of the representation of the Irish College of Physicians, from 2 to 3, and of the Irish University, from 3 to 4 each; (3) A new clause which declares that curricula shall be, as nearly as practicable, uniform throughout the kingdom.

Your Committee being of opinion that the Bill, though excellent in principle is faulty in detail, and that it will not be satisfactory unless it be amended, has not petitioned in its favour, and intends to urge, with all the influence of the Association, the amendments above referred to when the Bill reaches the Committee stage in the Commons. With that object, a communication setting forth the policy of the Association and suggesting co-operation, has been forwarded to the Medical Reform Committee of the British Medical Association and was considered by them last week, but a reply has not yet been received.

The Committee has reason to believe that the suggestions offered to Government are favourably regarded by them, and that if they can be urged influentially in the Commons, there is reason to hope that they may be incorporated in the Bill, none of them being inconsistent with the principles of the Bill or the intentions of the Royal Commission.

(To be continued.)

THE TENURE OF IRISH UNION MEDICAL OFFICERS.

THE action instituted by Dr. Dillon to compel the Irish Local Government Board to sanction his appointment by the guardians to the charge of the Listowel Workhouse has resulted, as was expected, in judgment for the Local Government Board. Dr. Dillon had, admittedly, paid a sum of money to Dr. Fitzmaurice, the surgeon of the Workhouse, for his resignation, and the guardians had supported him in the negotiation by electing him on no less than three successive occasions to the office so vacated, each of which appointments had been vetoed by the Local Government Board on the principle that a money payment for a succession to office could not be tolerated. Dr. Dillon's plea was, that he did *not* pay for the succession, of which he was quite certain whenever Dr. Fitzmaurice might resign, but, that he simply enabled that gentleman to surrender the appointment sooner than he otherwise would have done.

He, on these grounds, invoked the interference of the court of law, and Judge Lawson, in delivering judgment, expressed his opinion that the Local Government Board was not only fully authorised but perfectly right, under the circumstances, to remove Dr. Dillon. We much regret that the doctor was so badly advised as to go into Court with a case which would not hold

water on either moral or legal grounds, for if ever the veto of the Local Government Board is to be exercised, it is clear an appointment influenced by a money payment is the occasion. We doubt not that both Dr. Dillon and Dr. Fitzmaurice engaged in the transaction in ignorance of the law and in simple belief that it was legitimate, but they were utterly wrong, and it seems extraordinary that their legal advisers should not have told them so. It would be difficult to make the system of appointment to Poor-law medical offices more corrupt than it is in Ireland, where religion and politics are almost the only consideration, fitness and qualification being almost altogether ignored, but if there be a lower depth beneath, the abyss would be reached if the Local Government Board permitted the purchase and sale of these offices.

Outside this particular case, the decision of Judge Lawson has a supreme interest to Irish Workhouse Medical Officers, for the Act of Parliament authorises the Local Government Board to remove these officers whenever they "deem" them "unfit," and the learned judge says that he does not see that any Court has power to review any decision which the Board might arrive at in the exercise of their discretion. If this be the law (and, without doubt, the authority of Judge Lawson is of the highest), the medical officer is entirely at the mercy of the Local Government Board, and has, in fact, no tenure of office but their pleasure, which we know to be very generally the pleasure of the Boards of Guardians. We should be sorry to accept this ruling without question, being, as it is, entirely at variance with the advice which Dr. Kenny obtained when he instituted the action against the Board which terminated in his reinstatement, and we should, therefore, be glad if a case should arise which would enable a medical officer, with the right on his side, to challenge, at law, a dismissal by the Local Government Board. We have already argued that the Board must, in the exercise of such dismissory power, be prepared to give a reason which a court of law would consider sufficient, and that such reason must have regard to the officer's fitness for duty; therefore, though we are necessarily discouraged by Judge Lawson's opinion that the discretion of the Board is unlimited, we shall not be fully satisfied that that opinion is correct until a higher tribunal confirms the learned judge's view of the law.

TUAM GUARDIANS.

REPORT of the Tuam Dispensary Committee read, approving of the recommendation of the doctors for the appointment of Dr. Roughan, of Galway, as temporary substitute for Drs. Turner and Bodkin, at the rate of 3 guineas a week each. The union doctors were summoned to the Assizes.

The Chairman—Now gentlemen, listen to this, you will cavil and quarrel and divide over a few shillings a week to a poor cripple. Here is double the sum to be spent without a word. It concerns you all. It is of the rates, and these doctors are going and going to be paid for their time away out of the County Cess, which also falls on the ratepayers, so you are practically paying them on the double.

Dr. Bodkin—The case never occurred before where the two doctors of district were both summoned and had to leave. If one went and the other stayed, he would do his duty without remuneration, but here both of us must go.

The Chairman—That is all very fine, but provide your own substitutes; you are paid for your time away.

Dr. Bodkin—But we consider what we get not sufficient for what we lose in private practice.

The Chairman—I was and am a guardian for many years in three unions, and I never saw such a case as this before. Those gentlemen are going now, and they are to be paid their expenses out of the County Cess. In Glan, Dr. McDonnell is at present paying his substitute for the same Assizes, and providing his own expenses, and so the man at Castlereagh did last week in Roscommon. Our doctors are allowed 2 guineas a day at Assizes paid off County Cess.

Mr. Golding—The doctors when they sent in that notice have discharged their duties. They must attend to a Crown summons. My proposition is that the substitute get 6 guineas for the week.

The Chairman—They are our officers and are paid so much a year, whether sufficient or not I don't go into now. I hold they are not. This matter does not arise out of the duties as our officers. Let it go before public and before ratepayers. I never heard of it before.

Dr. Turner—I'll show my subpoena.

The Chairman—You are an officer of this Union and in our pay. Your time is ours.

Dr. Turner—But I'll have to go and go I will.

The Chairman—Well, now after, that challenge I will not sign any order. I'll vacate the chair if you like.

Mr. Golding—We don't want you to do that, but perhaps 6 guineas may answer and pass.

The Chairman—This is the thin end of the wedge. Once allow this and every doctor of the six you have in the Union will be claiming allowances for substitutes when summoned to Assizes or Sessions. There are two Assizes and six Quarter Sessions, and scarcely ever a time when the doctors are not summoned from some of the districts.

Dr. Turner said that he would simply tell them the law of the case. It was this:—

Board of Guardians are to determine the amount of remuneration, "if any," to be paid to a temporary substitute, therefore may refuse to pay such substitute, no matter what the cause of absence of medical officer may be; but if the substitute has been retained by the honorary secretary of the dispensary committee, or if his appointment as *locum tenens* has been recognised or confirmed by the committee or its responsible officer, then the committee is liable to pay a matter of simple contract, even though the Board of Guardians should refuse to do so. The substitute must be paid if the "medical officer be temporarily incapacitated by illness or other cause," so that a summons to assizes would be a good and sufficient reason for his absence, and for appointment of a *locum tenens*, see Article 22, Dispensary Regulations, page 242 Irish Medical Directory. Of course there can be no claim for payment unless the *locum tenens* has been appointed or his appointment confirmed by the dispensary committee.

Mr. Lyons—You did the same the other day with Dr. Lambert.

The Chairman—We did not. That was a fair case—leave of absence for sickness. Here it is entirely different.

Dr. Bodkin read minute showing ordinary meeting was held on Saturday in due course.

Subsequently, the Chairman wrote a minute that the doctors could go if they provided and paid their own substitutes.

[The law as stated by Dr. Turner is perfectly correct,

he can and must leave his district on a subpoena. He is paid by the Crown an insignificant fee in respect of his loss of private practice, and it is the business of the Committee to provide for his public duties. If they don't choose to do so that is their own affair. They must pay the absent doctor.—ED.]

KILMEAGUE DISPENSARY—NAAS GUARDIANS.

PAYMENT OF LOCUM TENENS.

LETTER received from the secretary to the Kilmeague Dispensary, stating that the payment of 10s a day had been sanctioned to Dr. Bray, Rathangan, who had acted as *locum tenens* in the absence of Dr. Sale, at the Assizes, as a Crown witness.

The Clerk—I am bound to say I never heard the like of that before. If a medical officer is summoned as a witness, and is paid two guineas a day from the Crown, and gets his salary as well, why the committee should pay him for a substitute is more than I can understand. I never knew of such a case before.

Mr. Owen—Is he bound to have a substitute?

The Clerk—I think so. It is now for the board to say whether they will refuse or sanction the payment of this money.

The chairman said that the letter did not state who was present at the committee meeting, which may have been composed simply of the chairman and the secretary. It was a monstrous thing to be paying a man 10s. a day as a substitute, when Dr. Sale was getting his salary and two guineas a day.

The clerk said that the board had nothing to do with the acts of a dispensary committee only so far as monetary matters were concerned.

Fee disallowed.

At a subsequent meeting the following was read:—

"Gentlemen,—Although I am quite irresponsible for the appointment or payment of a *locum tenens* when incapacitated from performing my duties by illness or retained by the Crown, I feel called on to notice some remarks made at the board on the 19th instant. I may state I was informed many years ago the Local Government Board decided it was a legal charge to pay a substitute for the medical officer of the Ballyboggin dispensary, Edenderry Union; and I may refer the guardians to the most recent case reported in the Mountmellick Union. Doctor Fisher's substitute was paid by that board while he was at Kilkenny Assizes in January last; so that it is not illegal, nor is it unusual in other places; yet I have always heretofore paid a substitute in such cases myself; but last year I was accused of exceeding the regulations when I required sick leave, and I now felt justified in strictly adhering to them in all cases; but as I am aware, should the board refuse to pay they would be mulcted in possibly three times the amount of legal expenses in addition, I have settled the account myself. At the same time, by so doing, I do not admit that I am bound either legally or morally to have done so.—Your obedient servant,
"GREGORY SALE."

[In our opinion Dr. Sale was very foolish—unless for reasons personal to himself—to pay a sixpence to his *locum tenens*. The Regulation entitles him to absence from his district when "temporarily incapacitated from duty by illness or other causes." A subpoena is unquestionably a reasonable "other cause," and the guardians could have been compelled to pay the *locum tenens* if Dr. Sale had not volunteered to do so.—ED.]

THE PURCHASE OF IRISH POOR-LAW OFFICES.

DR. DILLON AND THE LOCAL GOVERNMENT BOARD.

IN the Queen's Bench Division at Dublin, before Mr. Justice Lawson and Mr. Justice Johnson, in the case of *Ex parte* Dillon and the Local Government Board, Mr. D. O'C. O'Riordan, Q.C., moved on behalf of Mr. Dillon for a *certiorari* to bring up and quash a sealed order of the Local Government Board declining to recognise Dr. Dillon as medical officer of the Listowel Workhouse. Dr. Dillon was medical officer of the Ballyhorgan district in Kerry, and Dr. Fitzmaurice had been medical officer of the Listowel Workhouse. In September last, Dr. Fitzmaurice mentioned to Dr. Dillon that he was in embarrassed circumstances, and intended to resign his position as medical officer, and if Dr. Dillon gave him £75 he would resign forthwith. He (Dr. Dillon), believing he had a fair prospect of election, agreed to this. Dr. Fitzmaurice resigned, and on October 4th the Board of Guardians duly elected Dr. Dillon by 22 votes against 8 for Dr. Clancy. Mr. John Stack, the vice-chairman, and five of Dr. Clancy's supporters met and passed a resolution that it was undesirable to have as medical officer a gentleman who held the appointment of medical officer to a dispensary district, part of which extended fourteen miles from the workhouse. On October 27th twenty-seven members of the board wrote to the Local Government Board, pointing out that Dr. Fitzmaurice, when he was medical officer to the workhouse, also held a dispensary, and that Dr. Dillon's dispensary barely extended ten miles, and was not at all as populous as Dr. Fitzmaurice's district. The matter was referred to the board of guardians, and on November 22nd, by a majority of 24 to 5, the board approved of Dr. Dillon's appointment. On December 5th the Local Government Board wrote, refusing to sanction the appointment, and asking for information on a complaint made by Mr. John Stack, that it was notorious that Dr. Fitzmaurice, for a liberal pecuniary compensation, had agreed to resign in favour of Dr. Dillon. A complaint was also made by a Mr. Harman that Dr. Dillon did not reside within the Ballyhorgan dispensary district. On January 3 another election took place, and Dr. Dillon was elected by 22 votes to 9. Again the Local Government Board refused to sanction the appointment, and directed a new election, which took place on February 21st, when again Dr. Dillon was elected by 19 votes to 8 votes. The Local Government Board then issued the sealed order removing Dr. Dillon for unfitness.

Messrs. James H. Monahan, Q.C., and Hugh Holmes (instructed by Messrs. T. T. McCreedy and Son) appeared for the Local Government Board, and resisted the motion.

Mr. Justice Lawson, in delivering judgment, said the Local Government Board was a great public department, entrusted with the superintendence of the administration of the Poor-law throughout the country, and they were vested with large powers. Under the 33rd section of the Poor-law Act they had power to remove any officer at their discretion for unfitness, incompetency, or neglect of duty. In the exercise of their discretion they declared Dr. Dillon unfit; and suppose they gave no reason whatever for it, he did not see what power the court had to review what they had done. In the exigencies of the public service, they might say—"We consider him unfit," and nothing more. But the reason was disclosed by Dr. Dillon, who had candidly stated he gave Dr. Fitzmaurice a sum of money, which led to his resignation. He had no hesitation in saying that giving a man a sum of money to procure his resignation of a public appointment was an offence at common law. In the face of such a state of things, any public department ought to declare that Dr.

Dillon was unfit to hold office, and if that was not done those offices might be put up to public competition. The Local Government Board, in the exercise of their discretion, had taken an effectual mode of preventing it by declaring Dr. Dillon unfit for the office. He agreed they had rightly exercised their discretion. At the same time, he was free to believe that neither Dr. Dillon nor Dr. Fitzmaurice knew exactly the legal consequences of what they did. The application would, therefore, be refused.

FEEES TO MEDICAL WITNESSES.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR

SIR,—I enclose a document from Dublin Castle which may interest your readers. Having been summoned by the Crown to attend as witness at the Limerick Assizes on the 6th of March last, I left my house on that morning at 8 o'clock, or thereabouts, and was not able to be at home until 7.30 o'clock p.m. same day. The case I was engaged in was the last called; I had to sit in court all day. I was tendered £2 2s. and ordinary fare for car and railway for twenty-one miles. I refused the sum as I held that I did not return home until a long time after Court rose, that a day that advanced well into the night could not, in any civilised country, be considered a legal day. Your readers will see how grossly mistaken I was. The reply of the Under Secretary will open their eyes. They will also have to note that they will have to spend fourteen hours travelling, going before a grand jury, tramping about from post to pillar, and sitting in court all day, for the magnificent consideration of £2 2s. Of course they are supposed to fast all day, for there are no refreshments to be had in court houses, and if one had forethought or time enough to furnish himself before leaving home, he might find out that the animal propensity of eating would be deemed *contempt of court*, and for a doctor, who should know better, there would be no excuse.

I am, &c.,

THOMAS HAYES, M.D., M.R.C.S.

Rathkeale House, Rathkeale.

March 31st, 1884.

Dublin Castle,
21st March, 1884.

SIR,—I am directed by the Lord Lieutenant to acknowledge the receipt of your letter of the 12th inst.; and to state that according to the scale of allowances to prosecutors and witnesses at Assizes and Quarter Sessions, the allowance to a doctor residing in the town, or immediate neighbourhood, where the trial takes place, is £1 1s., and if detained in Court for more than three hours, an additional guinea. When summoned to attend as a witness in any other town, the allowance is £2 2s. for every day he is necessarily detained from home, together with 10s. for each night he is so detained, and an allowance for travelling expenses.

The day is taken to commence at 6 o'clock a.m., and to end at 8 o'clock p.m.

I am, Sir,

Your obedient Servant,

R. G. C. HAMILTON.

Thomas Hayes, Esq., M.D.,
Rathkeale.

[We entirely sympathise with our correspondent, but we know of no remedy for the very great grievance of which he complains. In one respect the letter from Dublin Castle is very important, for it lays down, for the first time, a definition of a witness's day. If a witness is obliged to leave home before 6 a.m. in order to attend court, or if he does not arrive home until after 8 p.m., it is clear that he is entitled to payment for a second day, according to the declaration of the Under Secretary.—ED.]

IRISH POOR-LAW INTELLIGENCE.

MEDICAL FEES UNDER THE LABOURERS' DWELLINGS' (IRELAND) ACT.

DR. DARLEY, Q.C., the County Court Judge of Wicklow, last week delivered a judgment upon a claim made by Dr. Halpin, Medical Officer of Health for Wicklow, against the guardians of the Rathdrum Union, which will be hailed with satisfaction by the profession. Dr. Halpin had been directed by the sanitary authorities, under the Labourers Act, to institute inquiries as to whether certain houses required to have their accommodation increased. After inspecting twenty-two houses he furnished his account, but the guardians declined to allow him anything for his services, alleging that, being in the receipt of a salary as medical officer, he was not entitled to make any charge.

The Judge stated that he was entirely against the guardians in this contention, and that the Local Government Board had informed him that, in their opinion, the medical officer of health should be paid, and he, accordingly, gave a decree for the full amount (£22) with costs. The question here decided by the judge of the County Court will be brought before the higher court in Dublin by the Irish Medical Association within the next month, by an action taken on behalf of the medical officer of health against the Youghal guardians.

The guardians have entered a defence to the action, and the object of the Association in taking the case into the superior courts is to obtain a decision which will govern all similar claims throughout Ireland. It is, however, very satisfactory that the view taken by the Association is now confirmed by the judgment of the county court judge and, as regards the equity of the case, by the Irish Local Government Board.

MEDICAL MAGISTRATES.

IN the House of Commons last week, Mr. Sexton asked the Chief Secretary to the Lord Lieutenant of Ireland how many workhouse or dispensary medical officers in Ireland had been appointed to act in the commission of the peace since the rule was made excluding such officers from the Commission; how many of the medical officers so appointed were protestants; whether, with reference to the case of Dr. Flannery, of Tubbercurry, county Sligo, it was the fact that Mr. Reynolds, of Tubbercurry, was appointed to the commission of the peace, although as manager of the bank acting as treasurer to the local union, he was disqualified

from acting as an ex-officio guardian; and, whether, having regard to the provision which prevents a Poor-law medical officer from acting as an ex-officio guardian, and the fact that many such officers actually hold the commission of the peace, the rule excluding them from the commission would now be reconsidered.

Mr. Trevelyan said that since 1872, when a rule was made to exclude workhouse or dispensary doctors from the commission of the peace ten medical gentlemen had been appointed magistrates, but with regard to eight of the ten the records of the Hanaper Office did not show whether they were, or they were not, dispensary officers. Two were appointed by the Lord Chancellor with the knowledge that they were dispensary doctors, but the rule to the contrary had not then been brought to his lordship's notice. The official records did not show the religious professions of these gentlemen. Previous to the case of Dr. Flannery, the present Lord Chancellor had declined to appoint dispensary doctors, and he believed the rule was a wise one, and ought to be maintained. As to the case of a gentleman who was a manager of a bank that was not a disqualification for the magistracy.

FEES FOR SANITARY PROSECUTIONS.

AT the Bruff Quarter Sessions, before T. Purcell, Esq., Q.C., County Court Judge, the following case was decided:—Dr. Henry Donovan, of Killinane, sued the Kilmallock Board of Guardians for £7 7s. for attending on seven occasions as witness in prosecutions under the above Act. The Guardians were represented by counsel instructed by the solicitor for the Board. Mr. O'Shaughnessy, of Charleville, appeared on behalf of Dr. Donovan.

Dr. Donovan, on being sworn, produced the written orders of the Board for his attendance at the Petty Sessions on the several occasions. The defence made by the Guardians was that it was part of the doctor's duty as Medical Officer of Health to assist at those prosecutions. The learned chairman, in giving his decision, said that the duty of the Medical Officer of Health consisted in inspecting and reporting on nuisances, and that the additional duty of attending as witness under the Act, when not "included in the salary," should be paid for by the guardians. A decree for the full amount with costs was accordingly given.

POOR-LAW SUPERANNUATION.

A MIDWIFE of Kilmegaw Dispensary, Naas Union, has been obliged to resign from rheumatism contracted during her duties of over eleven years. She had two medical certificates, but there was such opposition shown when a superannuation was mentioned, it was

believed to be useless to bring the question to a division; although a midwife had been given an allowance after a shorter service a couple of years before, because she had the necessary religious qualification.

THE HEALTH OF DUBLIN.

ACCORDING to the Quarterly Summary just issued by authority of the Registrar-General, the number of deaths registered in the Dublin Registration District during the quarter ending March 29 amounted to 2,435, affording an annual ratio of 27·7 in every 1,000 of the estimated population. The average rate registered in the first quarter of the ten years 1874-83 was 33·6 per 1,000 persons.

The ratio of deaths north of the Liffey was 27·3; south of the river, 32·8; in the suburban districts, 18·7 in every 1,000.

The ratio of deaths registered in London during the quarter was 20·3; in Glasgow 25·7; and in Edinburgh 20·4 in every 1,000 of the population.

The deaths from zymotics were 239, being 75 under preceding quarter, and 189 under average for the first quarter of the ten years 1874-83.

Deaths from scarlatina, which in the preceding three months amounted to 137, fell last quarter to 65, being 4 under average. There has also been a material diminution in the number of cases of this disease receiving treatment in the Dublin hospitals.

The total number of deaths from fever registered is 65, being 18 over the number for the preceding quarter, but 30 under average. Thirty of the 65 deaths recorded last quarter were from typhus, being 17 in excess of the deaths from this cause in the preceding three months, but 3 under average; 29 (or 19 under the average) were from enteric fever.

Thirty-six deaths were caused by whooping cough (being 25 under average), and the remaining deaths from zymotic diseases comprise 25 from diarrhoea and dysentery, 10 from diphtheria, 8 from erysipelas, 3 from measles, &c.

DROGHEDA UNION.

LABOURERS' DWELLINGS.

A BILL was sent in by Dr. Smythe for inspection of houses under the Labourers' Act.

	March 28, 1884.
One house at Ford of Fin	£1 0 0
Two at Greenanstown	1 0 0
Four at Stamulen	1 0 0
Attending at Julianstown Petty Sessions in case of Guardians against owners of houses at Bettystown Cross.	1 0 0
For attending at the Board Room to give evidence under the Labourers' Act.	1 0 0
	5 0 0

P. J. SMYTHE, L.R.C.S.I., L.M.,
L.R.C.P.E.,
Sanitary Officer.

Mr. Everitt—I really think the doctor's labors should not be got for nothing: we are only getting the fine end of the wedge in now. We should beg of the doctors to report on all the houses in the union, go through the whole union, and examine every house, and then the doctor should get so much and the SSO so much. I would say £10 for each doctor; I would not object to that at all.

Mr. Dowdall—Then you will defer dealing with this?
Mr. Everitt—I would say that the doctor should get £10 and the SSO should be also paid; let them go through the whole union. It is time enough; write to him that it will be considered in July or August.

CORRESPONDENCE.

ABUSES OF POOR RELIEF IN IRELAND.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—I have been for nearly seven years a dispensary medical officer, and during that time have exerted myself to try and limit the abuse in the class of persons obtaining medical relief. Having, I must confess, failed signally, I now write to you, Sir, to know, would it not be possible to get the Local Government Board to define who are poor persons. I am at present attending a farmer in my district who holds twenty-five acres of land, and at the last committee meeting of my dispensary I brought the ticket before the members, who considered the man entitled to dispensary relief, as he was not in affluent circumstances. Surely such persons were never intended to obtain medical relief!

I find the abuse increasing daily, as since the land agitation a class of men are becoming members of dispensary committees who do not scruple to give tickets to those not entitled; but as the law at present stands the unfortunate dispensary doctor has but poor redress. Knowing the interest you have always taken in our grievances, I trouble you with this letter, and am

Yours very truly,
AN OVERWORKED AND BADLY-PAID
DISPENSARY DOCTOR.

[It would certainly not be possible to induce the Local Government Board to define the words "poor person," but it would be quite possible, we think, to combat the gross abuses of the system by improving the system of cancelling tickets.

These abuses have their strength in the fact that the system affords no ready opportunity of appeal by the medical officer against a fraudulent ticket, and in the fact that the tribunal to which the appeal is to be made is composed of the persons who are themselves the originators and patrons of the abuse. It was some years since proposed by the Irish Medical Association to pass an Act empowering the magistrates at Petty Sessions to cancel a ticket on good cause shown. If this were done the medical officer might make his appeal within a week, and to independent judges, and the proposition seems reasonable.—ED.]

EXCHANGES BETWEEN IRISH DISPENSARY DOCTORS.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—I have often thought that a great boon would be conferred on the Irish Poor-law medical officers by allowing them to exchange positions with the sanction of their respective committees. How many medical men in indifferent health living in large towns or crowded cities would be anxious to exchange the turmoil and worry of large centres of population for the calm and retirement of the country? And, on the other hand, how many young, ardent, medical men holding country dispensaries in which there is little to do would be glad to find more extensive fields for their irrepressible energies? There are, I doubt, not many doctors reading

in cities with delicate families, who would be most anxious to change appointments with a *confrère* residing at the sea-side. There are also many medical men in the country with large families, the education of whose children is for them a matter of the most serious consideration. Education cannot be had cheap only in cities or large towns. Hence it is that I think I am right in saying a doctor in the country with a large family would be anxious to exchange with one in town having no family, and *vice versa*. From experience I believe it is injudicious for a young practitioner to set up in "*his own country*," but circumstances often oblige him to do so, having no interest elsewhere. It would be often well for him if he could put a hundred miles between himself and his relations. Moreover, we are all liable to error, particularly when young and inexperienced, and the consequences of a serious mistake made in early life will haunt the perpetrator for years. I have known a practitioner who, just after being appointed to a dispensary, mistook a case of pregnancy for ascites, and ordered a warm bath, in which the neogonos was nearly drowned. This happened about twenty years ago, and it is fresh in the memory of the people yet. The life of the doctor to whom it occurred has been a failure, and he does not make £5 yearly by private practice. If that man could exchange appointments with another, and begin again in fresh fields and pastures new, being well read, he would be probably successful. I believe I have said enough to show how desirable it would be to allow medical men in the Poor-law service to exchange posts.

Yours, &c.,

DISPENSARY HACK.

[Our correspondent's remarks seem to point to a permanent exchange and not to a temporary exchange for a few months, which might be made without either party vacating his office. In either case his suggestion is worthy of notice, and we see no reason why it should not be widely acted upon, in cases in which both dispensary committees would be willing. For a temporary change of scene for a few weeks there would be little difficulty in arranging, but for a permanent change it would be necessary that each party should vacate his office, and permit it to be advertised, and should go through the form of an election which would be hazardous. We fear the Local Government would not recognise an exchange otherwise effected.—Ed.]

IRISH MEDICAL ASSOCIATION.

REPORT OF PROCEEDINGS.

From 20th November, 1883, to 15th April, 1884.

(Adopted at Ordinary Meeting of the Council, held 15th April, 1884),

MR. WILLIAM THOMSON, Chairman of Council,
in the Chair.

(Continued.)

LABOURERS' (IRELAND) ACT.

THE case referred to in the *ad interim* report (pp. 284, 285) which has been selected to test the liability of Boards of Guardians to pay reasonable remuneration to Dispensary Medical Officers for their services in connection with the improvement of labourers' dwellings under the "Labourers' (Ireland) Act," has not yet been heard in Court; but Mr. T. A. Purcell, Q.C., and Mr. John N. Gerrard have been retained as counsel on behalf of the Association, and it is expected the case will soon come up for trial.

The following correspondence on the subject has occurred:—

Irish Medical Association,
Royal College of Surgeons,
3rd December, 1883.

SIR,—Referring to previous correspondence (viz., my letter of the 24th, and your reply thereto, of the 29th of

October), respecting the remuneration of medical officers of health for services rendered in inspecting and certifying [as to the condition of labourers' dwellings in conformity with Section 5 of the Labourers' (Ireland) Act, I am directed to state that the Council of the Irish Medical Association have given special consideration to the subject and—in view of the terms of that Section—are unable to concur in the interpretation put upon the words of the Section by the Board. I am respectfully to submit that the statement that a representation when presented to the guardians "must be accompanied by the certificate of a sanitary officer of the union" should be read to mean that for the satisfaction of the Sanitary Authority the opinion of some person known by them to be skilled and experienced in sanitary matters should be presented to them. I am furthermore to point out that, according to the wording of the 5th section, *any* medical officer of health within the Union might legally be employed to inspect and certify, and it therefore does not appear to have been intended by Parliament to compel the particular medical officer of health for that portion of the Sanitary Authority's district referred to in the "representation" to give his services as part of his official duty under the Public Health Act.

The Council of this Association are unable to regard the examination of houses respecting which no specific nuisance is alleged (as a preliminary to the rebuilding or repairs of such houses) as coming within the duties of the medical officer of health as defined by the 11th Section of the Public Health Act, and by the general sanitary orders issued by your Board; and they therefore must respectfully dissent from the proposition that the medical officer is, in a legal sense, bound to perform such a duty; they contend, moreover, that if such services are rendered, they should be paid for by the persons engaging them—whether ratepayers or the Sanitary Authority—as entirely outside official duty.

While urging these considerations upon your Board's attention, the Council admit that it is very desirable that the function in question should be performed preferably by the medical officer of health of the district, but they consider that a general understanding as to the fee payable for same should be arrived at. It appears beyond question that the certificate of *any* medical officer of health of the Sanitary Authority is receivable as evidence in support of a "representation;" and as it will be admitted that the medical officer of health for any portion of the Sanitary Authority's district than that referred to in such representation might reasonably decline to inspect and certify gratuitously, it appears obvious that the medical officer of health for the district referred to in the "representation," is entitled to reasonable remuneration for his inspections and reports notwithstanding the interpretation of the law (in which the Council do not coincide), that it is a part of his duty as medical officer of health to inspect and report.

The Council therefore respectfully ask the Local Government Board to consider the propriety of issuing a general circular to boards of guardians throughout Ireland, expressing an opinion on the part of the Board that a reasonable fee ought to be paid, and suggesting the amount thereof.

The adoption of such a course by the Local Government Board would, the Council believes, prevent inconvenient disputes from arising on the subject, would greatly encourage the medical officers of health to give their services with willingness, and would prevent injustice being done which, in the absence of such an expression of opinion by your board, would certainly occur.

I am, Sir, your obedient Servant,
ROBERT BROWN, F.R.C.S.I.,
Hon. Sec. to Council.

To this communication the following reply has been received:—

No. 43435—1883.
Miscellaneous.

Local Government Board for Ireland,
Dublin, December, 6th, 1883.

SIR,—I am directed by the Local Government Board for Ireland to acknowledge the receipt of your letter of the 3rd inst., relating to the duties and remuneration of Medical Officers of Health under the Labourers' (Ireland) Act, 1883, and in reply, I am to state that, as a rule, the Local Government Board believe that the certificates required under the Act have been obtained from the Medical Officer of Health in the sanitary district concerned, although the terms of the 5th section of the Act admit of the certificate being given by any sanitary officer of the Sanitary Authority to which the representation is made.

The Local Government Board for Ireland will be prepared to communicate the views to the Sanitary Authority in any case in which difficulties or disputes may arise with respect to the discharge of the duties referred to or the remuneration of the medical officer of health, but the Board do not deem it necessary at present to issue a circular on the subject.

By order of the Board,

W. D. WODSWORTH, Sec.

NOTIFICATION OF INFECTIOUS DISEASES.

The Executive Committee of the Dublin Sanitary Association having invited this Association to join them in a deputation to the Chief Secretary to urge upon him the necessity for legislation regarding the notification of infectious diseases, the Committee of Council assented on the distinct understanding that no other method of notifying than that of Mr. Meldon's Bill should be brought forward.

The Royal College of Surgeons also joined in the deputation, which was received on the 17th January last, having been introduced by Mr. Maurice Brooks, M.P., and Mr. Findlater, M.P. Dr. Robert M'Donnell, past President Royal College of Surgeons; Mr. Edward Hamilton, President of the Dublin branch of the British Medical Association; Mr. Robert O'Brien Furlong, Chairman of the Dublin Sanitary Association; Dr. A. H. Jacob, President of the Irish Medical Association; Mr. Edward H. Bennett, Vice President of the Royal College of Surgeons; Dr. Duffey and Dr. J. W. Moore addressed the Chief Secretary in favour of the principles of Mr. Meldon's Bill, which they put forward as the only method suitable for Ireland.

Mr. Trevelyan, in reply, said it appeared that there was absolutely no dissent amongst the deputation as to the question of extending the system of notification to Ireland, and in fact over the kingdom. Neither was there any dissent as to the great advantage which had resulted from that system in those towns and cities where it had been adopted. If that had been their only business, he could not have detained them beyond two or three minutes. Undoubtedly he could have at once acceded to the wish of the deputation for the notification of infectious diseases in Ireland if there had been only one bill. Most of the speeches which he had listened to came to a narrow point to which the gentlemen who spoke attached very great importance, and upon which they had quite made up their minds—minds of such a nature that the greatest respect must be paid to any conclusion they arrive at. He was, however, unwilling to express any definite opinion to-day on the subject. He would consult with Sir Charles Dilke, and obtain a great deal of information of such a nature that it could only be obtained from prints and documents, and which would probably con-

firm everything that had been said by the deputation to-day. If the statement which had been made that in 99 cases out of 100 the system which finds favour with the deputation would be as effective as the system which had been adopted in the English towns was confirmed it was a matter of great importance, and would be a very strong argument in favour of their views. He was very anxious, indeed, to get information as to the views of those medical men who had experience of the system in those towns where it was worked, and if any of the deputation could suggest where he could obtain it he would be happy to receive it. Had any evidence been given in regard to this particular point before the committee?

Dr. Jacob replied such evidence had been tendered to the committee, which sat in 1882, but the committee had declined to receive it.

Mr. Trevelyan continued to say it was quite plain that before any attempt was made to extend the system to Ireland and the whole kingdom this point must be cleared up. The Government would use great diligence in coming to a conclusion, and would be very considerably influenced by the very moderately expressed opinions he had the pleasure of hearing to-day. Those opinions, he was quite convinced, proceeded in the largest degree from public spirit and philanthropy.

The President had an interview with Mr. Hastings, M.P., when in London in last February, for the purpose of urging him to adopt Mr. Meldon's Bill as a substitute for his own compulsory Bill, at which interview he ascertained that Mr. Hastings did not intend introducing his own Bill in the present session, and that if Mr. Meldon's Bill came forward, he would consider it with a view of accepting it, if possible, as a settlement of the question. Mr. Hastings did not, however, think that any bill had a chance of passing this session, in view of the opposition of Messrs. Hopwood, Burt, Thomassen, P. Taylor, and other representatives of the Vigilance Association.

Local bills containing compulsory notification clauses have been since introduced for Brighton and Croydon, and they have been remitted to a committee similar to that which considered bills of this class last year. Both these bills are strongly opposed by the medical practitioners of the respective towns, and the President has had communications with Dr. Carter, of Liverpool, hon. sec. of the Association for opposing such bills, with a view to combined action against these local bills.

PRISON SURGEONS.

As notified in the *ad interim* report (pp. 285, 286), an appeal was lodged on behalf of this Association against the decision of the Recorder of Galway in the case of *Dr. Rice v. The General Prisons Board*; Dr. Rice's claim being remuneration for services rendered while performing the duties of the prison surgeon at the request of the Governor of the prison. The Committee of Council are gratified at being able to report that when the case was heard on appeal a decision in favour of Dr. Rice was given.

Of late, reference has frequently been made in the reports of the Committee of Council to the refusal on the part of the General Prisons Board to pay for the services of medical gentlemen acting for prison surgeons during their enforced absence from duty on Crown summons or otherwise; but it is right to state that, judging by the correspondence on the subject, the General Prisons Board appeared to be quite willing to pay in such instances if only permitted to do so by the Treasury, and as no appeal has been lodged against the decision above referred to, it is assumable that the General Prisons Board willingly accepts that decision. This suit has been won really against the Lords' Commissioners of Her Majesty's Treasury.

(To be continued.)

IRISH POOR-LAW INTELLIGENCE.

THE TRAFFIC IN DISEASED MEAT BY THE DUBLIN POOR-LAW GUARDIANS.

THE observations which we recently made respecting the disgusting trade in the flesh of cattle dying of lung-fever which is carried on by the Dublin guardians with the apparent approval of the Privy Council authorities has given rise to considerable criticism in the *Dublin Daily Express* and others of our contemporaries, but nothing has been said by the advocates of this traffic to cause us in any way to modify our expression of disgust that those whose special function it is to watch over the health of the poor should themselves share the nefarious gains arising from the sale of this fever-laden carrion for consumption by the families of the artisans of Dublin. Indeed, what has been said on the other side rather confirms our condemnation of the practice. The Chairman of the North Dublin Guardians replies that "the best proof that the use of the flesh of pleuro-pneumonic cattle does no harm is that it has gone for so long without causing disease"—a statement which we entirely deny. There is, indeed, no specific disease which can be identified as the direct result of eating diseased meat, but there is no question that it acts as an irritant poison, producing diarrhoea, dysentery, gastritis, anthrax, and other diseases of blood-poisoning, and anyone who looks at the Registrar-General's returns for Dublin can satisfy himself that these diseases are, from some cause or other, enormously and unusually prevalent and fatal in that city, and we believe that that prevalence is in a great degree chargeable against the sale of this noisome carrion by the Dublin Guardians. At any rate, it may be reasonably taken for granted that fever-laden meat is unwholesome, and it remains for those who defend its use to prove that it is not sufficiently deleterious to justify its prohibition. We invite them to prove this by comparing the statistics of diarrhoea and other allied diseases in Dublin and in towns in which diseased meat is not publicly sold.

"An Indignant Guardian" writes to say that the Guardians do not make any profit by the sale of pleuro-pneumonic meat. We insist that they do. They sell for £5 the carcase of a cow which is worth nothing except for manure or boiling down. If they did not do so they would lose, not £10, but £15 by each animal

destroyed, and inasmuch as they seek to recoup themselves for their payment to the owner of the animal by selling its flesh for consumption by the poor at less than a fourth of its health value, they must be held to have engaged in this traffic with the full knowledge that the meat is, by reason of the disease, not fit to be sold at the market price of wholesome meat. Indeed, "An Indignant Guardian" makes no concealment of this, for he states that, "though the paupers at the unions are not allowed to get the meat, there is nothing to prevent its being sold to guardians, editors, and all others who can pay 10d. per pound for it." Such a confession coming from one of the vendors of the article in question needs no comment from us.

As to the public health aspect of the matter, we can offer no statements more convincing than those published by the Medical Officer of Health for the City of Dublin in the *Dublin Medical Journal* of December 1, 1877. We are obliged to omit much that is strongly corroborative of our view, for which we have to refer our readers to the article itself.

After describing at length the development of the lung fever and the changes to be found on post-mortem examinations—being those, in fact, of the most acute and violent form of epidemic febrile disease—Dr. Cameron proceeds:—

The malady is the result of a blood-poison; the animal is in a highly febrile condition, and its lungs—the great purifying agents of its system—are rendered more or less incapable of performing one of their functions, namely, the purification of the blood. We do not believe that the flesh of oxen affected with this malady is an immediate poison; it does not act like arsenic or strychnine. If it be a poison at all it is a slowly acting one. In this respect it resembles water which, though foul, nevertheless does not contain the poison of a specific disease. Such water produces diarrhoea, and other maladies, but as a rule not in all cases, and generally only when used for some time.

There is, however, evidence that the flesh of cattle affected with pleuro-pneumonia has produced disease in man. Professor Gamgee states that in a convict establishment, in which the flesh of animals affected with pleuro-pneumonia was constantly consumed, there occurred from 40 to 50 carbuncles per month amongst 1,520 persons. On the discontinuance of the use of diseased meat the carbuncles ceased to appear.

According to the Registrar-General of England, the deaths from carbuncles and phlegmons have increased enormously since the introduction of contagious lung

distemper into England thirty-five years ago. *Apropos* of this statement it is worth noting that boils, anthracoses, and carbuncles have, during the last few months, been exceedingly common in Dublin. This is significant, for during that period the North Dublin Union Board of Guardians have been most active in selling, or at least in permitting to be sold, carcases of oxen affected with pleuro-pneumonia to the Dublin butchers.

Dr. Letheby, Medical Officer of Health for London, traced to the use of one quarter of beef the illness of 66 persons, of whom one died. The cow from which the meat had been obtained had been affected with pleuro-pneumonia, and the meat had been made into sausages; but Dr. Letheby found that this had been done whilst the meat was quite fresh.

According to the late Dr. Livingstone, Europeans and natives who used the flesh of oxen affected with pleuro-pneumonia suffered severely from malignant anthrax.

At least 100 persons have made complaints to us with respect to the quality of meat—nearly always beef—and which they alleged had caused them nausea and severe diarrhoea. We are perfectly satisfied that many cases of diarrhoea and of other diseases result from the use of diseased meat, but as the diseases generally make their appearance after the bad meat has been consumed, it is all but impossible to trace effect to cause in such cases.

In September, 1877, the Corporation of Dublin addressed a circular letter to every medical man in the city or county:—

"1st.—Do you consider the flesh of oxen killed whilst suffering from contagious pleuro-pneumonia fit for food for man?

"2nd.—If you consider that such flesh may be used under certain circumstances, please state whether or not it is fit for food in the second stage of the disease, in which the lungs are usually much increased in size, partially hepatized, and sometimes more or less infiltrated with pus?"

Out of the 250 medical men who expressed opinions upon the subject, 220 replied in the negative to both queries. That is, 88 per cent. of the 250 medical men who replied were of opinion that the flesh of animals affected with pleuro-pneumonia was under no circumstances fit food for man.

The circular letter was also addressed to the Medical Officer of Health of every town of more than 20,000 inhabitants in the United Kingdom. There were received 75 replies; four of the Medical Officers of Health declined to express any opinion upon the subject; 56 were of opinion that the flesh of oxen affected with pleuro-pneumonia was unfit for food; and 15 considered that it might be used under certain circumstances. The great majority of the Dublin medical men and the Medical Officers of Health who stated that the flesh of pleuro-pneumonic oxen might be used as food, considered that in the second stage of the disease it was unfit for use.

Dr. Cameron then gives in detail the opinions of the leaders of the profession in Dublin, strongly condemnatory of the use of pleuro-pneumonic meat.

With respect to veterinary opinions upon the subject, very little need be said. Mr. Fleming, in his work on "Veterinary Police," is strongly of opinion that pleuro-pneumonia does not render the flesh of oxen unfit for food, and he does certainly make out a strong case in support of his views. Professor Gamgee is exactly of an opposite opinion. Some years ago, when the first real attempt was made in Dublin to prevent the traffic in diseased meat, an application was made to the Lord Mayor to order the destruction of the carcase of an ox affected with pleuro-pneumonia. We were forcibly supported by Professor H. Ferguson. The application was granted. Upon that occasion Professor Ferguson

informed us that he had invariably found pleuro-pneumonic beef to produce diarrhoea in dogs fed with it.

Circulars were sent by the Public Health Committee to the twelve veterinarians who are practising in Dublin and its suburbs. Six only replied, all of whom considered the flesh of pleuro-pneumonic animals unfit for food in any stage of the disease.

IRISH MEDICAL ASSOCIATION.

REPORT OF PROCEEDINGS.

From 20th November, 1883, to 15th April, 1884.

(Adopted at Ordinary Meeting of the Council, held 15th April, 1884),

MR. WILLIAM THOMSON, Chairman of Council,
in the Chair.

(Continued.)

DISPENSARY MEDICAL OFFICERS' SUBSTITUTES.

Dr. Hanlon, of Portarlinton, a member of the Association, informed the Committee of Council that he had acted as substitute for the medical officer of the Cloneygowan dispensary district during his illness (two weeks), and that, although he had been duly appointed as such by the Dispensary Committee at £3 3s. a week remuneration, the Board of Guardians of Mountmellick Union refused to pay him the full amount £6 6s., on the ground that Dr. Hanlon had not been formally appointed as substitute until some days after he had begun to discharge the duties.

The facts of the case are:—Dr. Tabuteau, the medical officer of the district, suddenly became seriously ill, and at once provided for the discharge of his duties by Dr. Hanlon; and in a few days (as soon as he felt himself able to do so) he reported his incapacity for duty to the hon. secretary of his dispensary committee, who thereupon convened a special meeting of the Committee, at which Dr. Hanlon was appointed substitute from the date of the commencement of Dr. Tabuteau's illness, at £3 3s. a week remuneration. The observance of the specified formalities in this case (owing to the nature of Dr. Tabuteau's illness) occasioned some slight extra delay, and the Mountmellick Board of Guardians sought to take advantage of it by repudiating the act of the Dispensary Committee.

The Committee of Council accordingly instructed Mr. Clifford Lloyd, Solicitor to the Association, to take proceedings to recover Dr. Hanlon's remuneration, and on the hearing of the case a decree for the amount claimed, with costs, was given.

The following report of the trial is copied from the *Leinster Express*, of 5th April, 1884, heard before Joseph Clarke, Esq., Q.C., County Court Judge:—

IMPORTANT TO POOR-LAW MEDICAL OFFICERS.

Dr. Hanlon v. The Mountmellick Board of Guardians.

This was an action to recover the sum of £6 6s. remuneration alleged to be due by the defendants to the plaintiff for having acted for a fortnight as temporary medical officer of the Cloneygowan dispensary district. Mr. Roe (acting for Mr. Clifford Lloyd, Solicitor for the Irish Medical Association), appeared for the plaintiff; Messrs. T. and H. Turpin appeared for defendants.

Mr. Roe, in moving the process, said—This is an action brought by Dr. Hanlon, of Portarlinton, against the guardians of the Mountmellick Union for the recovery of £6 6s. for fees due for medical attendance in connection with the Cloneygowan Dispensary in the Union of Mountmellick. Of that dispensary Dr. Tabuteau is the medical officer, and he being struck down suddenly by

illness, the dispensary committee, in pursuance of the powers invested in them under act of parliament, and the orders of the Local Government Board, appointed Dr. Hanlon as a *locum tenens* for Dr. Tabuteau, so that the wants of the poor might be attended to. The time of the attendance was one fortnight, and the sum charged was the ordinary thing for temporary services. Dr. Hanlon is a highly respectable medical practitioner, and, fortunately perhaps for himself, he is not dependent on the Mountmellick board of guardians. But at all events he gave his attendance in pursuance of the powers vested in the committee, and why he is not paid I am puzzled to know, and why it is a certain portion of guardians who call themselves "Nationalists" —

Mr. H. Turpin—Don't import these things.

Mr. Roe—It is a noisy section of the guardians opposes the payment of these £66s. for the services rendered to the sick poor of the district. The month previously, I am instructed, the guardians paid two other gentlemen in the union who filled the same position as Dr. Hanlon, without murmur or complaint. Perhaps these two gentlemen were more in concord with their feelings, but Dr. Hanlon and Dr. Tabuteau not being of the same stuff, and their mode of thought being different, they resisted paying these £66s. The dispensary committee passed the resolution that Dr. Hanlon should act as substitute for Dr. Tabuteau, and none of the committee were against it. I have only to say that if every doctor who is brought in this way for a temporary purpose is resisted in this manner, it will be very difficult to get any medical gentleman to give his services. I will now call Dr. Hanlon and Mr. Phillips, the chairman of the dispensary committee, and there is no more kind-hearted man, and no man more anxious to look after the interests of the poor.

Dr. Hanlon, the plaintiff, swore that in the beginning of December he was called in by Dr. Tabuteau, who is medical officer of the Cloneygowan dispensary district. Dr. Tabuteau was ill, and unable to attend to his duties as medical officer. Witness discharged the duties of medical officer from the 3rd to the 17th December. Witness had acted as *locum tenens* occasionally during the last thirty years, and was paid by the guardians.

Cross-examined by Mr. Turpin—I was called in about the 2nd or 3rd December.

Mr. H. Turpin—Do you know if Dr. Tabuteau gave notice to the dispensary committee?

Witness—He was not capable of doing so. He was suffering from inflammation of the throat, which ended in abscess. He was unable to write a letter.

Could he get no one to write for him?—I cannot say that. Dr. Tabuteau did not go to Dublin while I was attending the dispensary.

Don't you know that he went to attend an operation which was being performed on a friend of his?—I don't know anything of the sort. He did not leave the house from the time I commenced to attend him. He was confined to bed for about six or seven days. I acted for Dr. Tabuteau while he was suffering from scarlatina. I have been in the habit of performing his duties when he was a day absent.

And he used to pay you himself?—No.

Do you swear that?—Whenever I was appointed *locum tenens* I was paid by the board.

When did you receive an official notification that you were appointed *locum tenens*?—I think about the 10th or 12th December.

And you were acting from the 3rd December to the 12th without being appointed by the committee?

Mr. Roe—I don't know any power in the board of guardians to revise the action of the dispensary committee.

Mr. Turpin—Is it not the habit of the dispensary committee to recommend payment of your remuneration to the board of guardians, and is it not on that they act?

Witness—It was never questioned before.

Did you not act on the faith of Dr. Tabuteau paying you himself?—No.

But you received no directions from the dispensary committee from the 3rd December to the 12th?—No.

Mr. William Phillips, J.P., chairman of the dispensary committee, produced the minutes of a special meeting of the committee held on the 12th December, appointing Dr. Hanlon as *locum tenens* during Dr. Tabuteau's illness.

In answer to Mr. Turpin, witness said he received a letter from Dr. Tabuteau, stating he was ill on the 9th instant, and he at once convened a meeting for the 12th instant.

His Worship—Mr. Turpin, surely this is a matter of common Christian charity. It is a matter of common Christian duty, and there ought not to be any point raised about it. I am sure you are the last man who would do such a thing, because I believe you are a thorough gentleman in every sense of the word.

Mr. Turpin—I am obliged to rely on the legal position of the guardians.

Mr. Phillips—It was insinuated that Dr. Tabuteau was well enough to attend his mother-in-law's funeral, but that is not the case. Dr. Tabuteau was not able to attend.

Dr. Tabuteau—I was not away at all.

Mr. Turpin—My case is shortly this; and though your Worship may now think it a case that ought not to be insisted on, I don't think your Worship, when you hear the article of the Local Government Board's regulation bearing on the case, you will think it such a hardship. Dr. Tabuteau took his appointment under the rules relating to the Poor-law Acts. He was well aware of the restrictions to which he was subject. The 22nd article provides: "If a medical officer of the dispensary district be temporarily incapacitated by illness or other cause from performing his duties, he shall immediately, if practicable, communicate with the chairman or hon. secretary of the dispensary committee, and shall recommend to the committee a medical practitioner qualified as hereinbefore provided to perform his duties during his temporary incapacity; and on the fact of the medical officer's incapacity becoming known, a special meeting of the dispensary committee shall be at once called for the purpose of appointing a temporary medical officer, and the committee shall report the circumstances of the case to the Board of Guardians, who shall, subject to the approval of the commissioners, determine the amount of remuneration (if any) to be paid to the temporary substitute." Dr. Tabuteau, according to the evidence we have heard to-day, was rendered unable to perform his duties on the 3rd December, and there was no satisfactory evidence that some one on Dr. Tabuteau's behalf could not have sent notice to the committee, informing them of his illness, on the 3rd or 4th December. But Mr. Phillips has told your Worship he got no notice until the 9th December. I submit that the dispensary committee had no power under the circumstances to provide for the appointment during the period that intervened between the 3rd and 12th December. There is really no hardship on Dr. Hanlon, because Dr. Tabuteau is very well able to pay him. Dr. Tabuteau is medical officer of the dispensary district, and draws £160 a year. There is nothing whatever entitles your Worship to grant a decree against the Guardians, because the Guardians are not bound to grant any remuneration. But I dare say the Guardians will pay him £2 2s. as remuneration for the period from the date of the meeting of the committee (12th December) and the 17th December.

Mr. Richard Goodbody, clerk of the Mountmellick Union, produced the minutes of the guardians' meetings at which the Board refused to pay Dr. Hanlon. It appeared that at these meetings amendments were pro-

posed to the effect that Dr. Hanlon should be paid the full amount of his claim, but the resolutions refusing payment were carried by a majority.

Mr. Roe—Do you know whether a substitute for Dr. Higgins was paid a month before?

Witness—He was, but under different circumstances. Dr. Higgins had resigned.

Mr. Roe said that there was no question that the services for which the claims were made were rendered and properly rendered. If the medical officer of a district is temporarily incapacitated by illness from performing his duties, it was provided by the regulations that he should give immediate notice to the committee "if practicable." But however that might be, he submitted that the Guardians had no power to review the action of the dispensary committee. Dr. Tabuteau was incapacitated by reason of serious illness from discharging his duties, and as soon as he was able he communicated with the committee. If the article of the regulations were carried out in the manner that Mr. Turpin contended it should be, when a dispensary medical officer got ill a district would be left without a doctor until a meeting of the committee had been called and its proceedings had been approved of by the Board of Guardians.

Mr. Turpin—We make a fair offer of £2 2s., and it ought to be accepted. Dr. Tabuteau is drawing a salary of £160 a year.

His Worship made a decree for £6 6s., the full amount claimed by the plaintiff, and costs.

In answer to Mr. Roe, his Worship said he would not give witnesses' expenses.

(To be continued.)

THE HEALTH OF IRELAND.

ACCORDING to the quarterly return, during the quarter ended 31st March last, there was registered in Ireland an annual birth-rate of 24·2 in every 1,000 of the estimated population—and an annual death-rate of 19·5.

In England last quarter, the birth-rate represented was 33·1, and the death-rate 19·5.

The birth-rate in Ireland is 1·7 under average. The death rate is 3·9 below the rate of same quarter last year, and 3·2 under the average of five years.

The returns of pauperism, show on the quarter a decrease of 3,904 in workhouse inmates, and a decrease of 4,076 in out-door relief.

Compared with the first quarter of ten years, the number of workhouse inmates shows a slight decrease, but the outdoor relief is much in excess of the average.

Deaths.—The deaths registered in Ireland amounted to 24,149—annual ratio 19·5 per 1,000 of population, being 3·2 per 1,000 under the five years average for the corresponding quarter. The death-rate in Leinster was 21·6, Munster 18·3, Ulster 18·6, Connaught 15·0. The country death-rates range from 14·0 in Sligo to 26·9 in Dublin.

The general death-rate for last quarter is considerably below average, and is under the rate for the first quarter of any year since 1874. The zymotic rate, also, compares favourably with that for the corresponding period in past years, although whooping-cough caused 507 deaths, being in excess of any quarter since 1880.

Diseases.—The deaths from zymotic diseases were 96 under preceding three months and 333 under first quarter of 1883. The annual death-rate from these causes is 1·5 : in the first quarter of 1883 the rate was 1·7.

Small-pox.—There were no deaths from this disease recorded in any part of the country.

Measles.—The deaths from measles number 201, against 142 in the preceding three months, still the mortality is below average, and the disease was not widely diffused. The total number for the county of

Mayo was 53, being more than one-fourth of the mortality in the entire country.

Scarlatina.—Deaths, which had risen to 599, fell last quarter to 313, of which 82 occurred in Leinster, 78 in Munster, 140 in Ulster, and 14 in Connaught. In ten localities 210 of the 313 deaths from scarlatina occurred, so that although very fatal in some places, the disease was not generally prevalent in a virulent form.

Typhus.—The deaths (172) from typhus, are 108 under corresponding quarter of 1883, and 10 under the number for the quarter ended 31st December last.

Whooping-cough.—The decline in the mortality from whooping-cough has not been maintained, the deaths from this cause amounting to 507, being 89 over December quarter, and 6 in excess of the high number for the first quarter of last year.

Diphtheria.—Although there were only 83 deaths from this disease, the number is 24 over preceding quarter, and 14 in excess of the number for the first quarter of last year.

Simple continued and ill defined Fever.—The number of deaths is 88—an increase of 32 as compared with the preceding three months, but 21 under the number for the first quarter of last year.

Enteric Fever.—The number of deaths from enteric fever is 174, being 1 under the number for the preceding quarter, and a decline of 52 compared with the deaths in the first quarter of last year.

Diarrhœa.—Three hundred and twenty deaths were returned as caused by this disease, being 119 under corresponding three months of last year.

Cholera.—There were but two deaths ascribed to this cause.

Hydrophobia.—Three deaths from hydrophobia were returned as having been registered during the quarter.

THE DISEASED MEAT TRADE.

WE extract from the *Medical Press* an article on the sale of diseased meat by the Poor-law guardians in Dublin, which will be read with disgust and horror. We have called attention in our columns at various times to the abominable practice; but its character is pointed out with more emphasis and authority by a medical journal. We find that in a period of less than two years, ending last month, the number of animals affected by contagious diseases which were slaughtered in Dublin was 879. Of these 155 went to the knacker, but 724 were sold as human food to the poor of the city. Our police reports have frequently contained descriptions of the meat which was thus allowed to be sold. In many instances it was so putrid as to be absolutely poisonous, and prosecutions were brought; but where the quality was not so bad, the evil effects of it were left to develop themselves imperceptibly until disease was engendered and the death-rate increased. Even the poor excuse of keeping down the rates by selling the carcasses cannot be urged in this case with any force, for, while the disgusting and dangerous practice is carried on in Dublin, which would not be permitted in other cities, the fact is that the cost of carrying out the Contagious Diseases (Animals) Act is six times as great in Dublin as it is in Liverpool, Birmingham, Manchester, Edinburgh, Glasgow, Belfast, and London, all put together. In all those great cities the cost was £2,336, and in Dublin it was £12,732. This is a subject which calls for attention on the part of the Government. The control of the guardians is vested in this matter, not in the Local Government Board, but in the Privy Council; and it reflects little credit upon that body that the guardians should be allowed to sell for human food the carcasses of cows which have died of pleuro-pneumonia and other diseases, which, whatever may be said to the contrary, must be not only nauseous to think of, but prejudicial to health.—*Dublin Daily Express*.

IRISH POOR-LAW INTELLIGENCE.

CORRESPONDENCE.

IRISH POOR-LAW SALARIES.

TO THE EDITOR OF THE MEDICAL PRESS AND
CIRCULAR.

SIR,—I beg to enclose herewith an advertisement for a medical officer for Comber Dispensary in Newtownards Union, which appeared in the *Belfast News Letter* of the 10th inst. It will be seen that the munificent salary offered to a duly-qualified medical practitioner who may be appointed to the post is £60 per annum. This is the remuneration which is considered equivalent to the services of a medical man who in each year will attend at the dispensary 588 new cases, and who (throughout a district having an area of 16,650 acres and a population numbering 6,280) will have to attend at their own homes 165 new cases. I am taking the average numbers for three recent years. When the cost of a vehicle for conveyance to the residences of patients at a distance is deducted from the salary a very unsubstantial remainder is left. Hitherto the salary attached to the office of dispensary medical officer for Comber has been £100 per annum, but the very economical board of guardians of Newtownards Union (who can proudly boast that they have never yet granted a superannuation allowance to any of their retiring officers, regardless of the length of his service, his age, or state of health) have now apparently a good opportunity for cheeseparing by offering a salary reduced by £40 per annum, and utterly incommensurate with the faithful discharge of the duties of the appointment, relying, no doubt, on a spirit similar to that of trade competition to procure candidates. Would it be too much, Sir, to hope that those gentlemen who may offer themselves for the vacant appointment will, acting individually, or, preferably, by mutual agreement, refrain from presenting themselves as candidates before the dispensary committee as long as the paltry sum of £60 per annum is all that is offered? By such a course they would be consulting, not merely the general advantage of the profession, but ultimately their own individual benefit.

I am, Sir, &c.,

CYCLE.

[We hardly hope that the candidates will take the course suggested to them, though its wisdom in their own interest is obvious. No doubt the Newtownards guardians will get for £60 a medical officer worth that figure, and we wish the paupers of the locality joy of a medical adviser bought at such a price. He will, no doubt, have the necessary diplomas, but what more he may have to fit him for the charge of the lives and health of his pauper-patients remains to be seen.—ED.]

IRISH CONSTABULARY MEDICAL RELIEF TICKETS.

TO THE EDITOR OF THE MEDICAL PRESS AND
CIRCULAR.

SIR,—I would feel much obliged if you would inform me, whether the constabulary have a right to seek for tickets for people who meet with accidents, or are assaulted, knowing at the time that they are able and sometimes willing to pay for medical advice; and I would also feel obliged by being informed when the constabulary do obtain a red ticket for the medical officer to attend a patient at the barrack, or elsewhere, is the medical officer bound to give his opinion as to the nature of the case; and if he does give an opinion, can he legally claim a fee from the Government? The constabulary send me red tickets for parties able to pay, and then state that they have a right to my opinion as to the nature of the case.

A few days ago a merchant driving into this town met with an accident by his horse running away. I was called in to see this gentleman, who was suffering from a dislocation of the shoulder, which I reduced. He at once said he would send me my fee, which he did. This accident occurred early in the evening, but about nine o'clock, p.m., in my own house, I was informed that a constable had left a ticket for me immediately after the accident. I could not understand the meaning of this, and immediately went to the barrack to make inquiries, where I was informed that the issuer of the ticket was at fault, and not the constabulary. I may mention that this ticket was cancelled by the Dispensary Committee, who placed the following resolution on the book:—"No. 329..... was cancelled, and the Committee are of opinion that the medical officer is entitled to a fee; and they are of opinion that the police should not have applied for a ticket."

There was a man assaulted here on the fair day (12th inst.) who got some cuts on the head, which were dressed by our local apothecary. Afterwards the constabulary applied for a red ticket in order to get the medical officer's opinion as to the nature of the case, but the issuer of tickets informed the constabulary that the man was *able to pay*; but, notwithstanding this, they *pressed* for a ticket, but were refused. Apologising for the length of this letter,

I am, Sir, your obedient servant,

F. W. SMARTT, M.D.

1. The medical officer must attend on a relief ticket whether rightly or wrongly issued.

2. He is not called upon to give any opinion, and would act very foolishly in doing so without being secured his fee.

3. If formally and officially requested by the constabulary officer to give such opinion, he should do so in writing, and he would be unquestionably entitled to his fee for it, and could recover it by law.

4. If the ticket were subsequently cancelled, he could recover his fees for attendance on the patient, not from the constabulary, but from the issuer or the patient. The latter could not be held liable unless it could be shown that he or his representatives were party to the issue of the ticket. For instance, if he were brought to the station house in an insensible condition, he could not be afterwards made to pay.

We should be very glad of an opportunity to test the right of the authorities of Dublin Castle to issue the instructions upon which the constabulary act on these occasions. In any case, we hope our correspondent will insist on being paid on the cancelled ticket if he has not been already fully remunerated.

EXCLUSION OF DISPENSARY MEDICAL OFFICERS FROM THE MAGISTRACY.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR

SIR,—As a Poor-law medical officer, and one, like many more in my position, who has never been desirous of becoming a magistrate, permit me, nevertheless, to bring under your notice that the reply of the Chief Secretary to Dr. Lyons brings with it nothing short of a most audacious insult to the medical profession, or at least that very important branch of it, the Poor-law medical staff in Ireland. I address you, Sir, as the ever-vigilant guardian of our interests, begging you will arrange to have this insult fully brought under notice at the annual meeting, and a copy of a resolution—potent in its wording—passed at said meeting sent to this English Chief Secretary, who had to admit that our professional brethren in England were not insulted by him as we in Ireland are. It is patent to everyone that every other petty shopkeeper in the country and illiterate farmer is dubbed a J.P., whereas the educated member of an honorable profession is told that he should be excluded from those on whom that trifling bit of patronage is conferred.

I am, Sir, yours, &c.,

A SENSITIVE M.D. WHO WOULD NOT BE J.P.

LIST OF ENTRIES IN THE REGISTER OF THE BRANCH MEDICAL COUNCIL (IRELAND) FOR THE MONTH OF APRIL, 1884:—

- APRIL 1ST.—Falkiner, N. W., 45 Lower Dominick Street, Dublin, M.B. Univ. Dub. 1884.
2nd.—Fleming, H. H., Clifden, co. Galway, M.B. Univ. Dub. 1883, Bac. Surg. Univ. Dub. 1884.
3rd.—Smith, V. E., Sandymount, Belfast, M.B. and Bac. Surg. Univ. Dub. 1884.
3rd.—Warren, H. E. A., 6 Belgrave Park, Charleston Rd., Dublin, Lic. R. Coll. Surg. Irel. 1883.
4th.—Boles, W. S., 12 Belgrave Square, E., Dublin, M.B., Univ. Dub. 1883, Bac. Surg. Univ. Dub. 1884.
7th.—Daly, C. C. de B., 8 Upper Temple Street, Dublin, M.B. and Bac. Surg. Univ. Dub. 1883.
9th.—Neill, J., Tallaght, co. Dublin, Lic. R. Coll. Surg. Irel. 1879, Lic. and Lic. Mid. K. Q. Coll. Phys. Irel. 1883.
16th.—Manning, N. S., Ballyhaise, co. Cavan, Lic. R. Coll. Surg. Irel. 1883, L. and L. Mid. K. Q. Coll. Phys. Irel. 1884.
17th.—Cochrane, J. J., Virginia, co. Cavan, M.B. Univ. Dub. 1883, Bac. Surg. Univ. Dub. 1884.

- 19th.—Smartt, H. W., Castlepallard, Lic. R. Coll. Surg. Irel. 1883, L.A.H. Dub. 1884.
19th.—McCanlley, H. W., 9 Abercorn Terrace, Rathgar, Lic. R. Coll. Surg. Irel. 1883.
21st.—Doyle, P. J., Ballylarkin, Gorey, M.D. R. Univ. Irel. 1883.
21st.—McCauley, J. H., 39 Lower Dorset Street, Dublin, Lic. R. Coll. Phys. and Surg. Edin. 1884.
22nd.—McGrath, E. H., Grangeview, Cork, Lic. R. Coll. Phys. and Surg. Edin. 1884, L.A.H. Dub. 1884.
24th.—Drake, T. G., 3 Vergemount Hall, Clonskeagh, Lic. R. Coll. Surg. Irel. 1883, Lic. and Lic. Mid. K. Q. Coll. Phys. Irel. 1884.
25th.—Ward, J. S., Lisburn, Lic. R. Coll. Phys. Edin. 1884.

APPOINTMENT AND REMUNERATION OF SUBSTITUTES FOR DISPENSARY MEDICAL OFFICERS.

Irish Medical Association,
Royal College of Surgeons, Dublin.

SIR,—The attention of the Council of the Irish Medical Association has been frequently directed to the proceedings of Boards of Guardians and Dispensary Committees with reference to the above subject, respecting which the regulations of the Local Government Board seem to be very imperfectly understood, so that frequent disputes have arisen from the omission of the Dispensary Medical Officer to adopt the course indicated by those regulations. With the object, therefore, of preventing contests of opinion on this subject, the Council deem it desirable to recapitulate the regulation governing the matter, and to point out the course to be pursued by both medical men.

That course is governed by the 22nd article of the Dispensary Regulations, which is as follows:—

"If a Medical Officer of a Dispensary District be temporarily incapacitated, by illness or other cause, from performing his duties, he shall immediately, if practicable, communicate with the Chairman or Honorary Secretary of the Committee, and shall recommend to the Committee a Medical Practitioner qualified as hereinbefore provided (in Article 20), to perform his duties during such temporary incapacity. And on the fact of the Medical Officer's incapacity becoming known a special meeting of the Committee shall be at once called in accordance with Article 13 of the Order, for the purpose of appointing a temporary substitute for the Medical Officer; and the Committee shall report the circumstances of the case to the Board of Guardians, who shall, subject to the approval of the Commissioners, determine the amount of remuneration, if any, to be paid to the temporary substitute. And for the time during which such temporary substitute, appointed by the Committee of Management, shall act as Medical Officer, he shall perform all the duties of the Medical Officer, and shall duly enter up the books of the dispensary for such time, before any remuneration that may be agreed upon to be paid to him."

This regulation provides for the temporary incapacity of the officer not only from illness, but from any other cause outside his control, as for instance, a *subpoena* to give evidence in court, or an order from his Committee to perform duties incompatible with his dispensary work. In conformity with this regulation—the duty of a Dispensary Medical Officer, in case of his being "temporarily incapacitated by illness or other cause," is strictly confined—*first*, to his "immediately, if practicable, communicating with the Chairman or Honorary Secretary," and *secondly*, to "recommending a duly qualified *locum tenens*." The Medical Officer is not authorised to appoint his substitute, and the Committee have full discretion to act upon his recommendation, or

to disregard it, as they see fit—nor has he any authority whatsoever to make official arrangements with the *locum tenens* as to his remuneration, nor would any promises made by him be in the least binding either on the Committee or the Board of Guardians. The Medical Officer is simply directed to suggest to the Committee the name of a medical man who possesses the qualifications required by the regulations, and in doing so he will, of course, act rightly in recommending a practitioner who can conveniently and effectually discharge the duties for the advantage of the sick poor.

The Council do not fail to recognise the circumstances which may make it frequently desirable for the Dispensary Medical Officer to arrange *ad interim* for the discharge of his duty, until he shall have had time to communicate with the Chairman or Secretary of the Committee, and on these occasions the *locum tenens* may act upon arrangement with the Secretary until the Committee can be summoned; but in these cases, the practitioner who acts as *locum tenens* should recollect that his acting for the Medical Officer is irregular until he has had a definite appointment from the responsible officer of the Dispensary Committee, and that he has no claim whatever for remuneration except on a definite arrangement on the subject with that officer. He should also take care that the duty done temporarily by him at the request of the Medical Officer or the Committee's Secretary is covered by a subsequent resolution of the Committee by which his appointment is legalised, and the entire period of his service approved.

The *locum tenens* should distinctly understand that by such temporary arrangement he acquires no claim—moral or legal—upon the Medical Officer, and that if he omits to obtain, at the hands of the Committee or its responsible officer, a definite appointment and a definite understanding as to payment, he, in undertaking his duties, does so at his own risk, inasmuch as it is the regulation that Guardians "shall, subject to the approval of the Local Government Board, determine the amount of remuneration (if any) to be paid" to the temporary substitutes, and the Guardians have frequently, through a short-sighted policy, availed themselves of these words to refuse to pay anything for such services. The Council entirely dissent from this interpretation of the regulation, and hold that the words "if any," are introduced in order to free the Guardians from payment in cases in which the remuneration had been voluntarily arranged for between the Medical Officer and the *locum tenens*, and that in all cases the Guardians are bound to pay the sum agreed for with the Dispensary Committee.

As regards the continuance of the salary of the Dispensary Medical Officer during his illness, the Council desires to point out that the officer who complies strictly with the terms of the regulations, as above referred to, is entitled, *as a matter of right*, to receive his salary during the continuance of illness or other incapacity for duty, and it is not within the power of the Guardians to refuse payment, or to make any deduction from the amount, either for remuneration of the *locum tenens* or for any other purpose, nor is it within the authority of a Board of Guardians, by any resolution made at the time or previously, to alter the provisions of the regulations or to create a rule having such effect, and in case of their refusal to pay the *locum tenens*, the Dispensary Medical Officer is not bound in honour or in law to make good such payment, unless he has previously entered into an implied or expressed understanding with the *locum tenens* to that effect, which he is no way called upon to do.

The Council—though considering it necessary to offer to Poor-law Medical Officer this explanation of the regulations—have no intention of interfering with the discretion or personal convenience of such officers in this matter, and they trust that Medical Officers will interpret the regulations or the advice now offered

to them in any spirit which might interfere with the efficient working of the Poor-law Medical System or the proper care of the sick poor.

Your obedient servant,
ROBERT BROWN, F.R.C.S.I.,
Hon. Secretary to Council.

LIMERICK SANITARY AUTHORITY.

THE LABOURERS' DWELLINGS ACT.

MR. MILLANE observed that he believed the doctors' expenses for visiting the different houses in the union, and reporting thereon, in connection with the Labourers' Act, would be rather heavy.

Mr. Ryan supposed that they would be paid what was reasonable.

Mr. Millane—If they charge a pound a visit to each house it will be very nice.

Mr. Ryan—Oh, they won't charge that.

Mr. Millane—Or even ten shillings a visit would amount to a heavy sum. I may tell you that it is the opinion of people outside that the doctors would be entitled to a pound a visit, and there is a test case taken before the Queen's Bench from the Youghal Union in which they are looking for one pound a visit to each house.

Mr. Farrell—At all events the matter has not come before us yet.

Mr. Millane.—No matter. I do not think we will get out of it easily. We may have to pay £600 or £700 to the doctors for visiting the houses, while we might have had it done for £50 or so, if we had only entered into an agreement with them at the proper time.

Chairman—We made an order agreeing to consider the accounts of all officials by and by.

Mr. Millane—I am afraid the consideration of the doctors' fees will not be left to you.

Chairman—My opinion is that if the doctors visited these houses and reported them as unfit for human habitation, we can come at them for not reporting it before now, because they were bound to do so. They neglected their duty if this is the case.

Mr. O'Farrell did not think the Board would be put to any trouble in the matter.

The subject then dropped.

IRISH MEDICAL ASSOCIATION.

REPORT OF PROCEEDINGS.

From 20th November, 1883, to 15th April, 1884.

(Adopted at Ordinary Meeting of the Council, held 15th April, 1884).

MR. WILLIAM THOMSON, Chairman of Council,
in the Chair.

(Continued.)

DISPENSARY MEDICAL OFFICERS.

The Committee of Council are glad to observe that the guardians' award of the maximum superannuation allowance to Dr. Wilson, of Edgeworthstown, has been sanctioned by the Local Government Board, to whom the following letter relating thereto was addressed—viz.:

Irish Medical Association,
Royal College of Surgeons in Ireland,
3rd December, 1883.

SIR,—Having been informed that a resolution recently adopted by the Board of Guardians of the Granard Union will come before the Local Government Board for their

sanction of a pension granted thereby to Dr. Wilson, Medical Officer of Edgeworthstown and Street Dispensaries, in Granard Union, the Council of the Irish Medical Association respectfully appeal to the Local Government Board, in the hope that they will give their most favourable consideration to the special circumstances of the case.

The Council have been informed that Dr. Wilson, when proceeding to visit a dispensary patient for whom he had just received a dispensary ticket, met with a most serious injury of his foot and ankle joint, in consequence of the upsetting of his carriage, and not only has suffered intensely ever since from disease of the bones and ankle joint, but has been rendered a cripple probably for life, unable to perform his public duties or actively to engage in the private practice of his profession.

The Council have further been informed that Dr. Wilson, upon finding it necessary to resign his appointments, has, in consideration of his good service and the special circumstances, been voted by his Board of Guardians the maximum retiring allowance permitted by the Act of Parliament. The Council, therefore, earnestly hope that the Local Government Board may be pleased to sanction the full amount of that award in consideration of the following circumstances, viz:—

1. That Dr. Wilson was a faithful, zealous, and most efficient dispensary medical officer for many years, during which time his prompt and devoted attention to his duties, and the kind manner in which he discharged them, earned for him not only the confidence and respect of his dispensary committee and board of guardians, but also the love and esteem of the sick poor.
2. That the accident by which he has been reduced from a position of prosperity to one of almost complete dependence for support upon the amount of pension granted him, was incurred in the direct discharge of his duty as a dispensary medical officer, and without any default on his part.
3. That at the date of his accident the Local Government Board had not issued the circular which they subsequently promulgated, by which they advised boards of guardians that pensions granted to their officers in excess of the Civil Service scale would not be sanctioned by the Local Government Board. The Council respectfully submit that it would be very unjust to Dr. Wilson to limit the discretion of the guardians as to amount of pension by an order made at a period subsequent to the occurrence which entitled him to seek superannuation.

I am, Sir,

Your obedient servant,

ROBERT BROWNE, F.R.C.S.I.,
Hon. Sec to Council.

EXAMINATION OF DANGEROUS LUNATICS.

A dispensary medical officer, who is a member of this Association, had been called upon during the past few years by the justices to examine several persons alleged to be dangerous lunatics, and certify as to their mental conditions. In each case he was awarded by the justices the maximum fee of £2; but the Board of Guardians ignored the justices' order, and paid only one guinea in each case. The medical officer, in acknowledging the receipt of the cheques sent to him, took the precaution to state that the amount in each case was received *on account*, and ultimately sent in a bill for the balances due. The guardians refused to pay the claim, and the medical officer communicated with the Committee of

Council, who gave instructions to Mr. Clifford Lloyd, solicitor to the Association, to take legal proceedings to recover the amount claimed. The case was heard at Castleblaney Quarter Sessions on 28th March last, and a decree given for payment of the balance of the last fee only. The Committee of Council, acting upon the advice of the solicitor to the Association, appealed against the decision, in expectation of getting a decree ordering payment of the full amount claimed on all the awards of the justices.

MEDICAL WITNESSES AT COURT.

The Committee of Council are indebted to Dr. Hayes, of Rathkeale, for a communication relating to a correspondence which had recently taken place between him and the Under Secretary to His Excellency the Lord Lieutenant, as to the time at which a medical witness's "day" begins and terminates. The Under Secretary is reported to have ruled that "the day" begins at six o'clock a.m. and terminates at 8 o'clock p.m., as far as the obligations of medical witnesses are concerned. As no medical witness is allowed more than £2 2s. a day, one obliged to spend the entire of such a day of 14 hours is to be paid at the rate of three shillings an hour! as right and proper remuneration for a professional gentleman's time and skilled evidence without any allowance for loss of fees from private practice, or for the payment of his substitute during his necessary absence.

Under this ruling, it appears that any medical witness duly summoned to give evidence at Court who cannot, between 6 o'clock a.m. and 8 o'clock p.m., have begun and terminated his necessary travelling from home, &c., for the purpose of obeying the summons, is entitled to claim the specified fee for another day, no matter whether the commencement of his necessary movements for the purpose be much later than 6 o'clock a.m., or the termination thereof much earlier than 8 o'clock p.m., provided either *necessarily* extends further; or in other words, a medical witness obliged to leave home before 6 o'clock a.m. can claim two days' fees, even though he may reach home after attendance at Court long before 8 o'clock p.m., and, *vice versa*, a medical witness who cannot reach home by 8 o'clock p.m., no matter when he started, is entitled to another day's fee. Further, it appears that a medical witness who is obliged to begin his journey before 6 o'clock a.m., and is unable to terminate it before 8 o'clock p.m. the same day, is entitled to claim fees for three days. As the hours of commencement and termination of a medical witness's day has been so precisely fixed, the Committee of Council will be glad to be informed of any claims made for the second or third days' fees under such circumstances.

OBITUARY.

DR. RIGGS, OF ARMAGH.

ON the 3rd inst., Dr. Riggs, who had been ailing for the last few weeks, died. The deceased gentleman was medical officer of the Armagh Workhouse, which appointment he held since the 20th April, 1847. He took a lively interest in a great many public boards, amongst them being that of the Great Northern Railway Company, at the meetings of which he was a constant attendant. He was also one of the directors of the Armagh Gaslight Company, and recently he took a very active part in the agitation with regard to the Ulster canals.

IRISH POOR-LAW INTELLIGENCE.

IRISH MEDICAL ASSOCIATION.

ANNUAL GENERAL MEETING,
2ND JUNE, 1884.
REPORT OF COUNCIL

For the Year Ending 31st May, 1884.

MR. PRESIDENT AND GENTLEMEN,

During the past year your Council held 7 meetings, and the Committee of Council 43 meetings; 53 new members were elected, 7 resignations accepted, and 5 members died.

In this report your Council have approved of making but brief reference to subjects which have already been brought under notice in the periodical reports circulated amongst the members since last annual meeting.

MEDICAL ACT AMENDMENT BILL.

Your Council have endeavoured to have this Bill amended in accordance with the principles of medical legislative reform approved of by several successive annual general meetings of this Association.

The President of the Association (Dr. Jacob), at the request of your Council, lately proceeded to London, and had an audience of the Lord President of the Privy Council (Lord Carlingford), Mr. Lennox Peel (Secretary to the Privy Council), and the Lord President's Secretary, when he brought under notice the alterations in the measure which this Association desires.

Your Council have reason to believe that the suggestions offered to Government on behalf of this Association are regarded with favour, and, probably will be introduced into the Bill if they be influentially brought forward and supported in the House of Commons, as they are not out of harmony with the principles of the Bill, or the recommendations of the royal commission.

The amendments urged upon the attention of Government by the Association, are as follows:—

- (a) That the State examinee should be attached to a licensing body during his period of study, and that this affiliation should be necessary to registration.
- (b) That the curriculum and period of study should be uniform throughout the kingdom.
- (c) That the direct representative and the crown nominee should have seats on the divisional board for each division of the kingdom.
- (d) That university matriculants should not be admitted to the final examination at a reduced fee, unless they had fulfilled, at least, three years' study in arts.
- (e) That the surplus funds in the hands of the Medical Council and Divisional Board should be divided between the licensing bodies in proportion to the

educational and examinal work done by each respectively.

- (f) That the representation of the Irish College of Physicians on the Divisional Board should be increased.

The last of these amendments, however, has since been accepted.

Pending the decision of the Government regarding the introduction of the above amendments in the Bill, your Council have not taken any step to promote the progress of the measure; and they are of opinion unless these amendments, or the greater part of them, be adopted in the Bill, that measure should not receive any support from this Association.

The following correspondence between your Council and the chairman of the Reform Committee of the British Medical Association has taken place:—

IRISH MEDICAL ASSOCIATION,
ROYAL COLLEGE OF SURGEONS,

April 8th, 1884.

DEAR SIR,—I am requested by the Council of the Irish Medical Association to offer, for consideration of the Medical Reform Committee of the British Medical Association, the views of the Council respecting amendments needful to make the Medical Bill acceptable to the profession, and effectual as a measure of reform. Your Committee is, probably, aware that the Association, for many years past, urged persistently and emphatically the passing of a measure based upon the principles of this Bill, and it is, therefore, with much regret that this Association has found itself unable, in consequence of the many faults of important detail which the Bill contains, to take as active steps in support of it as it adopted when preceding medical reform bills were before Parliament. The object of this communication is, therefore, to enlist the co-operation of the Medical Reform Committee in obtaining such amendments in the Bill as will make the Bill generally acceptable, will weaken or neutralise the anticipated opposition to it on the part of the licensing bodies, and will make the measure as perfect in detail as the medical law of the future ought to be.

The Council submits that, considering the uncertainty of legislative prospects for the current session, the anticipation of a violent opposition to the Bill if views of opposing bodies be not, in some degree, met, and the probability that, if the Bill be not passed this session, no government will take the subject in hands for many years, the bodies interested in reform would act wisely by meeting hostility by conciliation, and arriving at a community of opinion and policy in respect of indispensable amendments.

The Council of the Irish Medical Association desires amendments in the Bill to meet the following objections, which I am to state very briefly:—

EDUCATIONAL.—(a.) That the primary administration of all medico-educational affairs is left *exclusively to the licensing bodies* which form the Divisional Boards—the representatives of the profession having no voice in these matters.

b. That as three—probably diverse—medico-educational schemes will be made by the Divisional Boards, and not by the General Council, it will be totally impossible for the latter body to bring these into even approximate uniformity, and we shall continue to have the same diversity of educational standards in the three divisions of the kingdom which the Bill is created to prevent.

c. That, as the student need not be in any way connected, either during his period of study or afterwards, with any of the recognised examining bodies, there will be no sufficient guarantee for the sufficiency of his primary examinations.

RE-CONSTITUTION.—(d.) That the direct representative is placed by the Bill in a subordinate position, and his influence minimised by confining it to the brief and limited, supervisory functions of the General Council, while the licensing bodies are given full control of all medico-educational arrangements.

COLONIAL PRACTITIONERS.—(e.) That the Bill will admit to home practice an unlimited number of American, colonial, and foreign practitioners, for whose education or examination up to the home standard no sufficient guarantees are required.

UNLICENSED PRACTICE.—(f.) That the law which has been heretofore used in England to check illegitimate practice is to be repealed without any adequate alternative being enacted.

g. That the Bill gives new power to the Medical Council to forbid defence associations or private persons to prosecute medical quacks, while it refuses the Council the same prohibitory powers in the case of dental quacks.

Finally, the Council of the Irish Medical Association expresses the opinion that the Bill deals most unjustly with existing licensing corporations. *Firstly*, by making no proper provision for allocating to their maintenance any part of the very large annual income which will accrue to the General Council. *Secondly*, in according to students of certain universities, which are nothing more than examining centres, the same privileges as those accorded to students of *bona fide* universities which educate, train, and examine, such privileges the having effect of a large money inducement to attract students to those universities.

I am desired to inform you that, if the Medical Reform Committee is willing to consider the amendment of the Bill in the matters here indicated, or in other directions, this Association will be glad to confer with your Committee, or, in any way, to afford any information desired.

I am, dear Sir, yours faithfully,

ROBERT BROWNE,
Hon. Sec. to Council.

In reply to this communication a letter was received from Dr. Waters, chairman of the Medical Reform Committee of the British Medical Association, informing your Council that the Committee had carefully considered the representations made, and had embodied their reply thereto as follows:—

NOTE 1.—(a) The divisional boards will only act under the supreme control of the Medical Council.

NOTE 2.—(b) The Medical Reform Committee are of opinion that the Medical Council cannot possibly sanction really diverse schemes.

NOTE 3.—(c) The Medical Reform Committee carefully considered the question of placing the direct representation on their respective divisional boards, and, while not opposing the proposal, cannot oppose the Bill on that ground. The proportion of direct representation on the Medical Council (four in eighteen) makes them a deal fewer, whereas one in a board of sixteen in Ireland could exert little influence in the divisional board. The Medical

Reform Committee do not oppose the proposal. They have pressed it on the attention of Government, and the Government are not hostile to the point. The Government, however, reply to the Medical Reform Committee that the demand has never been made by the Association or the profession, and that they have conceded all that has been asked.

NOTE 4.—(d) The clause has been strengthened in this year's Bill. The Medical Council will exercise supervision, but for this clause or something of the kind, M. Gueneau de Mupy, a professeur agrégé, physician to one of the large Parisian hospitals, on coming over to this country could not have acted as physician to the ex-King of the French without subjecting himself to pains and penalties.

NOTE 5.—(e) The present law against illegal practice is not as strong as that proposed in the present Bill; witness the failure in prosecution of an unregistered "doctor" by the Liverpool Defence Association quite recently, while the clause referring to such cases in the present Bill would have reached him.

NOTE 6.—(f) The Association has suggested that these prosecutions will be best placed in the hands of a public prosecutor.

FINALLY.—The Medical Reform Committee have no power to interfere in matters involving the pecuniary interests of the corporations or universities.

NOTA BENE.—The Medical Reform Committee will move clauses rendering it incumbent on the Medical Council to visit the examinations, &c., of the divisional boards, as of the very essence of their duties.

UNION OFFICERS' SUPERANNUATION BILL.

Your Council regret to state that no satisfactory progress has been made with regard to this measure, chiefly in consequence of the opposition of several Irish Members and the great difficulties in the way of legislation at present.

The expressed intention of Government is to have this Bill at first presented to the House of Lords by Lord Carlingford, the Lord President of the Privy Council—Mr. Herbert Gladstone, M.P., still taking charge of it in the House of Commons.

An offer of support by the Irish Members was made, provided the Bill was so altered that the granting of pensions to union officers should still be left to the discretion of the boards of guardians, subject to an appeal to the Local Government Board; but your Council decline to entertain such a proposal, so long as Government continues to express the intention to exercise every effort to pass the Bill in its present form at the earliest possible date, without, however, holding out any hope that that time may soon arrive.

LABOURERS' (IRELAND) ACT.

Your Council regret that, owing to unaccountable delays, the very strong claim by a Medical Officer of Health for remuneration for his services in connection with the improvement of labourers' dwellings, as referred to in recent reports, has not yet come before the Court, but it is expected that this case will be disposed of soon.

Your Council have noticed that a similar claim has already been adjudicated upon by Dr. Darley, Q.C., County Court Judge, at the late Wicklow Quarters Sessions. The medical officer of health (who is not a member of this Association) sued the Board of Guardians of Rathdrum Union for £11, as reasonable remuneration for having, in compliance with their instructions, examined and reported upon 22 labourers' dwellings for the purpose of the Labourers' (Ireland) Act.

The County Court Judge gave a decree for the plaintiff. When giving his decision, the judge is reported to have stated that the Public Health Act does not impose upon a Medical Officer of Health gratuitously the duty of inspect-

ing and reporting on labourers' dwellings for the purposes of the Labourers' (Ireland) Act, and that his opinion of the matter was borne out by the Local Government Board, the Secretary of that body having written to him to the effect that the Local Government Board considered the medical officer of health fairly entitled to be remunerated for his extra services in connection with the administration of that Act.

This appears to be the first and only legal decision on such claims, and it is an extremely important judgement.

NOTIFICATION OF INFECTIOUS DISEASES.

Your Council, recognising the great public advantage which would accrue from an effective and satisfactory system of compulsory notification of all cases of infectious disease to the Sanitary Authorities, supported a deputation to the Chief Secretary on the 17th January last. The deputation comprised representatives of the Dublin Sanitary Association, the Royal College of Surgeons, the Irish Medical Association, and the Dublin Branch of the British Medical Association. The Chief Secretary's attention was specially directed to the principles of the Bill for the Notification of Infectious Diseases (Ireland), introduced into the House of Commons in the Sessions of 1882 and 1883 by Mr. Meldon, M.P. The provisions of that Bill had been previously accepted as satisfactory by your Council, as well as by the College of Physicians, the Royal College of Surgeons, and the Dublin Branch of the British Medical Association, and, subsequently, they were adopted by the Dublin Sanitary Association. The principle advocated was that the penal duty should be imposed upon the householder or custodian of the patient, with regard to each case of infectious disease, to report the same forthwith to the sanitary authority, provided the medical attendant, if any, had not already voluntarily accepted that responsibility and the liability thereto attaching. The Chief Secretary admitted the importance of the subject brought under his notice, and said he would make further inquiries relative to it; and, further, that the Government would consider the subject as soon as they could conveniently do so, and would doubtless be considerably influenced by the opinions and statements brought under his notice, which, he was convinced, proceeded in the largest degree from public spirit and philanthropy.

PRISON SURGEONS.

Your Council have much pleasure in reporting that a very important precedent has been recently established relative to the payment of substitutes for prison surgeons during their temporary absence from duty on Crown or official business.

The surgeon of Galway prison, in compliance with an official order from the authorities, proceeded to Dublin to give evidence before the Prisons Commission, but, before leaving his duty, he suggested to the Governor of the prison that Dr. Rice was a fit and proper person to be employed to discharge the duty, and the Governor requested Dr. Rice to undertake the temporary medical charge of the prison. Dr. Rice, having performed the duties, claimed remuneration for his services from the authorities, but the General Prisons Board referred him to the Secretary of the Royal Commission, who referred him to the prison surgeon. The General Prisons Board then directed the prison surgeon to pay his substitute, but Dr. Rice declined to accept the payment offered, under protest, by that gentleman. The matter was then referred to the Lords Commissioners of Her Majesty's Treasury, who ruled that the prison surgeon should pay for the services of his substitute.

Dr. Rice having appealed to your Council for advice and support, your Council, in his name, took legal proceedings to recover from the General Prisons Board the amount claimed, but the Recorder of Galway gave judgment against Dr. Rice.

REPORT OF PROCEEDINGS.

From 20th November, 1883, to 15th April, 1884.

(Adopted at Ordinary Meeting of the Council, held 15th April, 1884).

MR. WILLIAM THOMSON, Chairman of Council,
in the Chair.

(Continued.)

SANITARY PROSECUTIONS.

The case referred to in last ordinary report (pp. 264, 265), in which a medical officer of health claimed £2 2s. for his evidence given at the request of his Sanitary Authority in a prosecution under the Public Health Act, was heard at Newry Quarter Sessions on the 15th Jan. last, and adjourned in order to obtain information from the Local Government Board as to the power or right of the Sanitary Authority to pay a fee in such case, no one appearing to know of the issue or terms of the Local Government Board's order of 11th November, 1878, under the 258th section of the Public Health (Ireland) Act, 1878.

The plaintiff in the case—viz., the medical officer of health, should have been able to give this information had he read and recollected the reference to his case above recited, and accordingly might have saved himself some trouble and another day's attendance in court to prove his claim.

NAAS BOARD OF GUARDIANS.

MEDICAL OFFICERS AND LABOURERS ACT.

AN application for payment of £6 6s. from Dr. Bleakley, medical officer at Blessington, for inspecting and reporting upon a number of unsanitary dwellings, came up for consideration.

Mr. Cotton said the amount was very small, and should be at once paid.

Mr. Fenelon—How many houses did he inspect?

The Clerk—All within a radius of a mile.

Mr. Fenelon—I read his letter to the board very carefully, and I cannot make out how many houses he inspected. I may state here that I, at the suggestion of the Board, got Dr. Barker, of Kilcullen, to inspect some in that locality, and he went over twenty-seven of them in one evening. He made his report, which I handed in to the guardians myself, and he never lodged a claim for a single penny for making the inspection. The reason why I want to know how many houses Dr. Bleakley inspected is that we may be assisted very much in measuring the remuneration he may be entitled to.

Mr. Cotton—I do not see how he could charge anything lower than he has done.

Mr. Driver—I propose that this sum be paid. It is not too much at all for three days' work.

Mr. M'Dermott—There might only be two or three houses within a radius of a mile.

Mr. Driver—Oh! goodness me (laughter.)

Mr. Fenelon—I dissent from this payment. I do not see why we should follow the example of any one in this matter, because a County Court Judge decided in favour of a medical officer the other day. The Kilcullen medical officer never asked for payment.

The Chairman—But he may do so yet.

Mr. Driver—The guardians of the district are in favour of the payment being made.

The Chairman—So far as my experience goes, I must say we are not overcharged.

Mr. Fenelon—Six guineas for three days would represent a large sum in the year. So far as I can learn he has applied for more than he is entitled to for the duty performed.

It was decided to pay the money.

ATHY UNION.

LEAVE OF ABSENCE.

THE Local Government Board forwarded the following letter.

"SIR,—The Local Government Board for Ireland observe from minutes of proceedings of the board of guardians of Athy union, on the 15th inst., that a communication was received from the medical officer to the workhouse to the effect that he would require to be absent from his duties for a few days during the week, and that the guardians appointed Dr. Kilbride to act as his temporary substitute, at a remuneration of £3 per week; and I am to state that the Local Government Board cannot recognise or approve of any arrangement under which a medical officer is to be allowed to absent himself from his duties at periods to be selected by him according to his convenience, such periods not being specified in the leave granted to him. The General Regulations of the Local Government Board do not admit of any officer performing his duties by deputy; and if leave of absence is granted to a medical officer under article 41 of the Regulations the guardians should define the actual time and extent of such leave. The Local Government Board must decline to sanction the payment of remuneration to Dr. Kilbride for his temporary services until they have further information on the subject, and they request that the guardians will be good enough to take the matter again into consideration.

Chairman—The Article in the General Regulations which they refer to is as follows:—

"If any officer or assistant appointed to or holding any office under this order, be at any time prevented by sickness or accident or other sufficient reason from the performance of his duties, the guardians may appoint a fit person to act as temporary substitute, and may, subject to the approval of the Local Government Board, pay him a reasonable compensation for his services, and

every such appointment shall be reported to the Local Government Board by the clerk to the guardians, as soon as the same shall have been made."

The matter was referred to Dr. O'Neill himself.

COMBER DISPENSARY.

A MEETING of dispensary committee was held for the purpose of making arrangements with regard to the appointment of medical officer for the dispensary, in the room of the late Dr. Frame (deceased). The Chairman said Dr. Frame had not only been a physician, but a true-hearted friend, and was respected by them all. In his death the public had lost a most faithful and devoted servant, whose place would be very hard to fill indeed. He did not think it was necessary for him to say anything further, but in his opinion it would be only right and proper that this committee should express to the friends of Dr. Frame, by a vote of sympathy, with deep regret at his death, and their sympathy with his relatives in their sad bereavement. A committee was appointed to draw up an address of condolence. The chairman said that there were three candidates for the vacant office, and the Guardians were of opinion that the salary should be £60 per annum, while the Local Government Board held that the salary should be £100. The secretary then read a letter from the Local Government Board stating that they desired to inform the committee of management of the Comber dispensary district that the salary at present fixed for the medical officer was £100 per annum, and that the committee had no power to alter that amount, that being a matter which rests with the Board of Guardians, subject to the sanction of the Local Government Board. A letter was also read from Dr. F. Scott, one of the candidates, stating that he had retired from the contest. Resolved "That the dispensary committee cannot proceed in the election of medical officer until the question of salary is settled by the Board of Guardians and the Local Government Board." The present *locum tenens*, Dr. Henry, was reappointed for another month.

NEWTOWNARDS GUARDIANS.

LETTER read from the Local Government Board enclosing the copy of a communication addressed to the committee of the Comber dispensary district, to the effect that the attention of the Board had been called to the advertisement in reference to the appointment of a duly qualified medical practitioner to succeed Dr. Frame. The salary at present fixed was £100, and the committee had no power to alter that amount, the fixing of the salary being a matter that rested with the Board of Guardians, subject to the sanction of the Local Government Board. The committee should be convened at once to issue a new advertisement, and the rate of remuneration should be the same as that received by the late medical officer of the district. Mr. M'Master said the committee had made a mistake in publishing the advertisement before the Board of Guardians sanctioned the amount of salary. He therefore, moved that the Board ratify the decision arrived at by the dispensary committee, and declare the salary to be £60 a year. Mr. J. Andrews, considered that £60 of a salary was quite inadequate, and the £40 additional would only involve a rate of four-tenths of a penny on the valuation of the entire district. He proposed that a fresh advertisement be issued, as suggested and directed by the Local Government, and that the salary be fixed at £100. The car hire for such a large district would amount to at least £1 per week. A vote was taken, when three voted for the amendment and seven against, and the motion fixing the salary at £60 was passed.

IRISH POOR-LAW INTELLIGENCE.

IRISH MEDICAL ASSOCIATION.

THE annual general meeting of this Association was held on Monday, 2nd of June, in the library of the College of Surgeons. The President of the Association, Dr. Jacob, occupied the chair.

Amongst those present were—Drs. Hemphill, Clonmel (the newly-elected President); Molony, Bolton, Carlow; Willes, Rathmines; Hepburn, Dublin; Ferguson, J. R., do.; Walsh, Kilmacthomas; O'Rourke, Crossakiel, Co. Meath; Monogh, J. P., Dublin; Tagert, do.; Kinkad, Galway; Leonard, Athenry; Cutler, Waterford; Nixon, F. A., Dublin; Auchinleck, do.; Chapman, do.; Kelly, Drogheda; Moore, J. W., Dublin; O'Reilly, F. J., Trim; Jacob, Dublin; Corley, do.; Moore, C. F., do.; Stokes, do.; Brody, Limerick; David Jacob, Maryborough; Darby, Bray; Purcell, Dublin; Truell, J. P., Wicklow; Boyce, Stillorgan; Oulton, Dublin; Croly H. G., do.; Stoker, Thornley, do.; Ormsby, do.; Minchin, do.; Little, P. C., do.; Slevin, Longford; Wharton, Dublin; Pollock, Blackrock.

The report, which we publish elsewhere, having been read, Dr. Tagert moved the adoption of the Report of Council. He said that the report was a clear and able statement, showing that a large amount of work had been done during the past year by the Association in the interest of the medical profession both in town and country.

Dr. Hemphill, of Clonmel, seconded the resolution.

The Chairman, in putting the resolution, said that the report had intimated that the judge of assize had declared that a medical substitute should be paid by the Prisons Board, but notwithstanding that the Treasury had sent directions to the Prisons Board to deduct from the salary of the medical officer the payment made to the substitute. In this way they were again brought into collision with the Treasury. Nevertheless, he believed the result would be favourable to the Association. The judge of assize had expressed in the strongest terms his opinion on the subject, and his reasons for the judgment he had given. There was no legal authority for such a deduction from the salary of the medical officer. Now, as to the payment of substitutes for dispensary medical officers, he had received from a gentleman in the country a communication which he had received from the Local Government Board on the subject. This gentleman had been subpoenaed to attend as a witness at the assizes, and in due course he nominated his substitute, but the board of guardians refused to pay the substitute, and appealed to the Local Government Board, and that board replied stating that when a dispensary medical officer was summoned as a witness at the assizes on business unconnected with the public service of the union it was the usual practice for the medical officer to provide a substitute at his own expense, as it was

presumed that he would be remunerated for his attendance at the assizes. Now, the remuneration for attendance as a witness at the assizes was so insignificant that he (the President) did not think it at all justified a deduction being made from the salary of the medical officer for the payment of his substitute. With respect to the appointment of medical officers to the magistracy he had reason to believe that the Government had caved in. Dr. Lyons had taken up the question very warmly, and within the last few days he (the President) believed that a medical officer had been appointed to the magistracy. However, a memorial would be prepared on the subject, and he trusted that it would be extensively signed.

The resolution was adopted.

Dr. A. H. Corley moved the following resolution:—“That the council be instructed to continue to urge Government to adopt the amendments of the Medical Act Amendment Bill approved of by this Association, and that in the event of such amendments as seem to them necessary not being introduced into the Bill the support of this Association shall not be given to that measure.”

Dr. Truell seconded the motion.

Mr. Stokes, of Dublin, wished to propose an amendment. One of the amendments urged upon the attention of the Government was—“That the curriculum and period of study should be uniform throughout the United Kingdom.” In the Bill proposed, the “uniformity of fee” was left out. The question of finance might be a vulgar consideration, yet it was as important as any of the others, and if the amendment which he would now propose were not made, one of the great defects of the present system, and which had led to an exodus from this country to England and Scotland, would continue. He proposed that an uniformity of fee should be established. If the charge were thirty guineas here there would be nothing to prevent a Scotch body charging thirty shillings, or what they liked less than that charge. He would venture to suggest that in addition to the proposal that the curriculum and period should be uniform throughout the United Kingdom, the fee also should be uniform. He thought it would be very desirable to have that added to the resolution.

Dr. Bellew Kelly, of Drogheda, seconded the amendment, which, with the resolution, was adopted.

Dr. Darby, of Bray, moved—“That the Association having observed with much regret that in consequence of the persistent opposition given to it by certain members for Irish constituencies, the Union Officers' Superannuation Bill has not been pressed upon the attention of Parliament, re-asserts its opinion that the poor-law medical officer is entitled in equity to receive a pension, as a matter of right, whenever he shall be incapacitated from the discharge of his duty, and therefore respectfully urges the Government and Mr. Herbert

Gladstone to exercise with determination their influence in Parliament to pass, in the present session, a measure so generally approved and so just in principle. That a copy of this resolution be forwarded to the Chief Secretary, Mr. Herbert Gladstone, and the Vice-President of the Local Government Board for Ireland."

Dr. Bellew Kelly seconded the motion, which was adopted.

Dr. Moloney, of Tulla, moved—"That this Association approves of Mr. Meldon's 'Notification of Infectious Diseases (Ireland) Bill,' and hereby directs the council to exercise the influence of the Association in its favour, and to oppose any Bill which proposes that the duty of notifying infectious diseases to the sanitary authorities shall be made obligatory upon the medical attendant."

Dr. T. Purcell seconded the resolution, which passed.

Dr. Cutler moved the following:—"That the indiscriminate issue of dispensary tickets to persons whose circumstances do not entitle them to charitable relief is a practice grossly unjust to the medical officer, and to the ratepayers, at whose expense such relief is given, and its prevalence in Ireland demands the earnest attention of the Government authorities. That the legal precedents established by the Association, by the recovery of fees for services rendered on these tickets, are eminently satisfactory, and that the Council be requested to consider the propriety of testing the question whether the cancelling of the ticket is an indispensable precedent to the recovery of such fees." Dr. Cutler said the issuing of dispensary tickets was liable to great abuse in cities and towns, and that tradesmen and artisans who were able to employ a doctor had not the slightest scruple in taking the services of medical men for nothing. If certain restrictions were put on the issuing of those tickets an abuse would be prevented.

Dr. Leonard, of Athenry, said that after an experience of twenty-two years as dispensary medical officer he did not think that he had reason to complain, though he believed that many of his professional brethren had been very badly treated with regard to the issuing of those tickets.

Dr. O'Reilly, of Trim, said he spoke after an experience of sixteen years, and he suggested that no person should have the power to issue those tickets but the relieving officer, who usually lived close to the residence of the doctor, and who knew the circumstances of the people. He would be a responsible person, and he (Dr. O'Reilly) believed that the members of the Dispensary Committee would be glad to get rid of the responsibility which was imposed on them by law.

Dr. Molony did not concur with the suggestion of the last speaker, for the relieving officer could not know the circumstances of all the persons living in a district, some parts of which might be a dozen miles away from him.

Dr. W. H. Oulton spoke in favour of the responsibility being thrown on the relieving officer, and said that in Dublin and other cities those tickets were in many instances issued by publicans to persons who came into their place of business, had some drink, and got the order.

The resolution was adopted.

On the motion of Dr. O'Rorke, seconded by Dr. Kinkead, of Galway, the following resolution was adopted:—"That the action of Council in instituting a suit to establish the right of medical officers of health to payment for inspections under the Labourers (Ireland) Act is approved, such functions not being, in the opinion of the Association, a legitimate part of the duty of the medical officer under the Public Health Act."

Dr. Kinkead moved the following resolution:—"That the Association regards the exclusion of dispensary medical officers from the Commission of the Peace in Ireland as derogatory to the social and professional position of those officers, and entirely unjustified by

experience as to the manner in which the magisterial functions have been heretofore discharged by those officers who have held her Majesty's Commission; that the Council be requested to use their utmost influence to cause any understanding which may exist as to the exclusion of dispensary medical officers to be abrogated." Dr. Kinkead said he did not know any class of persons in whom the people would have more confidence than in the members of the medical profession, but it was not in reference to the right of medical gentlemen to hold the Commission of the Peace that reforms were required. When resident magistrates attended the assizes they were allowed as expenses £1 1s. a day, sub-inspectors of police received 15s. a day, but the doctor was supposed to live on starvation allowance, and he was rated at 10s. 6d. per day. The Association would do good service if it insisted on justice being done to men of education, intelligence, and social position, such as were the members of the medical profession.

Dr. Oulton seconded the motion.

Dr. Leonard, of Athenry, said he attended the last assizes at Sligo, and the beggarly pittance allowed to medical gentlemen was brought under the notice of the judge, who spoke to the Clerk of the Crown. The judge considered that three guineas a day was only a reasonable remuneration to allow him (Dr. Leonard), and 30s. a day expenses, so that he received £4 13s. per day, and that was the rate of payment now given to medical gentlemen coming from Sligo to Galway. The Crown Solicitor remonstrated with the judge, and said that he could not allow more than two guineas per day and 10s. hotel expenses, and that he had received a communication from the Castle to that effect. The judge replied that the gentleman who framed that circular was not fit to put gum on a halfpenny envelope. (Laughter.)

The resolution was adopted.

Dr. Thornley Stoker moved the following resolution:—"That the thanks of this Association are hereby tendered to the professional and general press for having advocated the fair claims of the medical profession, as well as for having given publicity to the proceedings of the Association, with reasonable commendation."

The resolution was adopted.

Dr. Hemphill, of Clonmel, having taken the chair as president,

Dr. Martin, of Portlaw, moved the following resolution:—"That the warmest thanks of this Association are hereby given to our late president, Dr. Jacob, for the dignified manner in which he has filled that office, as well as for the zealous interest he has ever evinced in the welfare and objects of the Association."

Dr. Chapman seconded the resolution, which was adopted.

Dr. Jacob expressed his acknowledgments, and

Dr. Hemphill said he felt that the honour done him was a compliment to medical practitioners in the country.

The proceedings then terminated.

The following gentlemen were elected officers and members of the Council for the year ending 31st of May next:—

President.—Dr. W. D. Hemphill, Oakville, Clonmel.

Vice Presidents.—Leinster: Dr. Edward Hamilton, 120 Stephen's Green, Dublin. Ulster: Dr. W. Malcomson, Cavan. Munster: Dr. John Russell, Thurles. Connaught: Dr. Heily, Roscommon.

Council.—Dr. C. Bent Ball, Dr. J. W. Boyce, Dr. Brown, Dr. William Carte, J.P., Dr. Chaplin, Dr. A. H. Corley, Dr. H. G. Croly, Dr. T. Darby, Dr. R. V. Fletcher, J. R. Harvey, W. J. Hepburn, A. H. Jacob, David Jacob, J. B. Kelly, Richard John Kinkead, James Martin, A. Meldon, G. J. Mackesy, R. M'Donnell, F. V. M'Dowell, G. Morrough, J. Molony, A. O'K. Nolan, J. F. Pollock, Sir G. H. Porter, T. Purcell, J. Ridley,

J. M. Tabuteau, R. M. Tagert, Wm. Thomson, J. W. Usher, J. L. Walshe.

Auditor.—Dr. Albert Croly, Rathfarnham.

THE DINNER.

The forty-fifth annual dinner took place in the evening in the Albert Hall of the College of Surgeons.

Dr. WM. D. HEMPHILL, President, occupied the chair.

On the right of the President sat Dr. Moore, President of the College of Physicians; Sir George H. Porter, Surgeon-in-Ordinary to the Queen in Ireland; Sir George Owens, Mr. Maurice Brooks, M.P., D.L.; Dr. Croker King, Local Government Board; and Dr. Jolliffe Tufnell.

On the President's left sat Dr. E. H. Bennett, the newly-elected President of the College of Surgeons; Dr. Edward Hamilton, Dr. Lyons, M.P.; the Registrar-General, and Surgeon-General Clarke.

Among those present were:—Mr. Purcell, Q.C.; Dr. Carte, J.P.; Mr. Pelham Mayne, Mr. H. G. Croly, Dr. Pollock, Dr. Anthony Corley (Vice-President of the College of Surgeons), Mr. Wm. Stokes, Mr. Lambert Ormsby, Dr. Hepburne, Dr. Robert Browne, Mr. J. A. Scott, Dr. Humphrey Minchin, Mr. Minchin, Dr. Purcell, Dr. A. H. Jacob, Mr. Arthur Benson, Dr. Duigenan, Dr. Chapman, Dr. Austin Meldon, Dr. Carte, Mr. John Brennen, Registrar Royal College of Surgeons; Mr. Purcell, Mr. Arthur Patten, Mr. Thomas Gick, Mus. Doc., Mr. Henry Beaumont.

After dinner,

The Chairman, in proposing the toast of the Queen, said they all had to express their deep sympathy with Her Majesty in the loss of her beloved son.

The toast was warmly drunk, and the National Anthem sung.

The Chairman then gave the toast of "The Prince and Princess of Wales and the rest of the Royal Family," observing that his Royal Highness the Prince of Wales had shown a marked interest in the question of the dwellings of the poor in connection with the Royal Commission now sitting—a commission which promised to confer great benefits in connection with the promotion of sanitary science. He (the President) said he could not but think that many of the evils that affected this country might have been mitigated if the children of the Queen had come oftener amongst us. (Loud cries of "Hear hear.")

The toast was heartily drunk.

Quartet—"Cytherea"—Sir R. P. Stewart.

The President then proposed the toast of "The Houses of Lords and Commons," and said he feared that the passing of the Medical Acts Amendment Bill was inevitable, and that they would have to accept it subject to any amendments that might be made in committee. He expressed the hope that the surplus funds would be appropriated in such a way as that these Colleges would not suffer. It seemed hard to take from licensing bodies that had done their duty well—such as the Irish Colleges of Physicians and Surgeons—the power of sending men out into the profession. He believed that if there was a uniform standard of education, with *bond fide* attendance at lectures and proper attendance at the hospitals, and notes taken at the clinical observations made, it would be better for the students themselves. (Hear, hear.)

The toast having been honoured,

Mr. Maurice Brooks, M.P., in responding, said he would take care not to introduce the subject of party politics—(hear, hear)—which had been happily banished from these halls. With regard to medical politics, he was given to understand medical men were all agreed and that there was not a scintilla of difference between them. (Oh, and laughter.) However, as there might be a difference amongst them, he felt bound to say—

and what he had heard confirmed him in the view—that it would be better for him to be careful when he ventured to express an opinion upon medical politics. Therefore he would also refrain from very much reference to medical politics. (Laughter.) He must, however, say that he took a deep and sincere interest in the question of the superannuation of the union medical officers. (Applause.) He regarded the conduct of the Government towards those medical officers as little less than iniquitous. (Hear, hear.) It would be a source of great privilege to him to do his humble share, in association with his learned colleague (Dr. Lyons) to correct that very serious injustice. He had carefully studied the various amendments to the Medical Bill—occupying, he thought, 33 pages—and they would receive his careful attention. As for the House of Lords, he regretted that there was no noble member present to speak to that portion of the toast. What he (Mr. Brooks) would say in reference to it was that he hoped the House of Lords would last (hear, hear, and applause)—so long as it should continue to do the good work that had marked its career hitherto. (Hear, hear.)

Dr. Lyons, M.P., also responded. He said he had always believed that one of the most useful ways in which a change could be effected in the House of Lords would be by incorporating the representatives of all the learned professions of the country, and he ventured to think that the time was coming when the recognition of the public position and importance of the great bulk of the profession to which they had the honour to belong should be accorded to them in this great assembly. In suggesting such a course he was not at a loss for a precedent. Six life peerages had been added in representatives of the legal profession to the House of Lords, and the feeling day by day was fast growing that a similar recognition could be fairly claimed by the profession of medicine. (Applause.) He believed such a recognition would materially increase the public capacity of usefulness of their profession, for many important questions could be much more successfully dealt with in the calmer atmosphere of the House of Lords; when for the next 10 or so years there was a certainty that questions of high political importance which greatly agitate the public mind would occupy the attention of the House of Commons. He believed the proposition he now referred to would come before very long within the domain of practical politics. With reference to medical legislation, he believed there should be a settlement on a new basis of the questions which had agitated the medical mind for the last 20 or 25 years, and he would ask the members of the profession to do their part by formulating their views in clear and unmistakable terms, so that they in the House of Commons might be informed of their opinions. (Hear, hear.) As to the representation of the profession in the magistracy of the country—(hear, hear)—there was no wish that the magistracy should be flooded with doctors—(No)—but he thought he fairly represented the general feeling when he said that when a man had a certain standing in the profession he should be free to be chosen for the magistracy irrespective of any arbitrary rules. He decidedly objected to the fact of a certain man filling a particular position disqualifying him from holding a position which was one of dignity and trust, and which was looked upon as a social mark carrying a certain amount of distinction throughout the length and breadth of the country. (Hear, hear.)

Song—"Afterwards"—J. W. King Mullen.

Surgeon-General Clarke responded on behalf of the army to the toast of the "Army and Navy," and Surgeon Henry Croly on the part of the navy.

Serenade—"Maiden Fair"—Haydn.

The toast of the "Colleges of Physicians and Surgeons" was then drunk.

Dr. William Moore, President of the College of Physicians, first responded, and spoke of the sympathy of his College with the objects of the Association. He insisted that the dispensary medical officers must have retirement allowances. Every other branch of the public service had, and why should not professional men in Ireland, who were in the public service, have it? (Hear, hear.) He also strongly deprecated the change proposed to be wrought by the Medical Amendment Bill.

Dr. E. H. Bennett, President of the College of Surgeons, next responded, and pointed out, in answer to the invitation of Dr. Lyons, that the Irish College of Surgeons had already closely formulated their opinions, and no later by a resolution passed by the College on Saturday last.

Cavatina—"Come into the Garden, Maud"—Balle.

The President gave the toast of the Dublin branch of the British Medical Association, whose useful and important operations he spoke of in warm terms of eulogy. That great organisation, which was in no sense a rival of the Irish Medical Association—(hear, hear)—was going to hold its third annual meeting this year at Belfast, and they wished it success. He hoped it might be a means of much benefit to the cause of medical science in Ireland. (Applause.)

The toast having been duly honoured,

Dr. Edward Hamilton responded, and said it was a source of great pride to him, as the president of the Dublin branch of an organisation whose members numbered thousands, and whose branches extended wherever British rule was known, to have the privilege of speaking on its behalf. They were not ashamed to follow in the path of the Irish Medical Association, which had proved so successful a pioneer. (Hear, hear.)

Quartet—"The Three Chafers."—Pruhn.

Sir George Porter proposed the toast of the President of the Irish Medical Association, whom he spoke of as an accomplished gentleman and distinguished county infirmary surgeon.

The toast was cordially drunk.

Dr. Hemphill responded.

Song—"Father O'Flynn."—Words by Graves. Music arranged by C. V. Stanford.

The toast of the "Visitors" was responded to by Mr. Pheham Mayne and Mr. Purcell, and the health of the Council and Officers of the Irish Medical Association and of the Press having been drunk, the company separated.

IRISH MEDICAL ASSOCIATION.

ANNUAL GENERAL MEETING,

JUNE 2, 1884.

REPORT OF COUNCIL

For the Year ending 31st May, 1884.

(Continued.)

YOUR council were not satisfied that the facts of the case had been fully submitted, and, acting under legal advice, notice of appeal was lodged against the Recorder's decision. When the case was heard at assizes, the judge gave a decree for the amount claimed, with costs, and ruled that, under the circumstances, the authorities were liable to pay for the services of the prison surgeon's substitute. No notice of further appeal has been lodged.

Your council consider that this decision is very noteworthy, and they would recommend medical gentlemen holding public appointments, when compelled to be absent from duty in such instances as crown summonses or official requirements, merely to nominate, but not appoint or make any arrangement as to the payment of

their substitutes; leaving it to the latter to take the steps necessary to recover from the proper source the amount of their claims for services rendered. The medical officers will thus most effectually resist the imposition of unfair deductions from their salaries.

WORKHOUSE MEDICAL OFFICERS.

Regarding the order of the Local Government Board of 18th December, 1882—relating to the delegation to boards of guardians of the right to dismiss medical officers of unions upon sufficient grounds—which was referred to in last annual report (pp. 206, 207) and appendix (pp. 233—245), your council have to report that no instance of dismissal of a workhouse medical officer has been brought under their notice, and, consequently, no opportunity has arisen of testing the legality of the Local Government Board's order of 18th December, 1882, in the Court of Queen's Bench.

DISPENSARY MEDICAL OFFICERS' SUBSTITUTES.

A member of the Association informed your council that he had acted as substitute for the medical officer of a dispensary district during his illness (two weeks), and that, although he had been duly appointed as such by the dispensary committee at £3 3s. a week remuneration, the board of guardians of Mountmellick Union refused to pay him the full amount, £6 6s., on the ground that he had not been formally appointed as substitute until some days after he had begun to discharge the duties.

The facts of the case are:—The medical officer of the district suddenly became seriously ill, and at once provided for the discharge of his duties by deputy: and in a few days (as soon as he felt himself able to do so) he reported his incapacity for duty to the hon. secretary of his dispensary committee, who thereupon convened a special meeting of the committee, at which the substitute was appointed from the date of the commencement of the medical officer's illness, at £3 3s. a week remuneration. The observance of the specified formalities in this case occasioned some extra delay, and the Mountmellick board of guardians sought to take advantage of it by repudiating the act of the dispensary committee.

Your council accordingly instructed Mr. Clifford Lloyd, solicitor to the Association, to take proceedings to recover the substitute's remuneration, and on the hearing of the case a decree for the amount claimed, with costs, was given.

This judgment is more important than it might from a hasty glance appear to be, inasmuch as it acknowledges the right of a dispensary committee to enter into a pecuniary contract as an authorised agent of the board of guardians, and makes the latter responsible for liability thereby incurred in such cases, notwithstanding the wording of Article 22 of the "General Rules and Regulations for the Government of Dispensary Districts," which declares that "the board of guardians shall, subject to the approval of the commissioners, *i.e.*, the Local Government Board, determine the amount of remuneration, if any, to be paid to the temporary substitute."

This decision further rules that a dispensary committee, by appointing a dispensary medical officer's substitute subsequently to the time he entered upon the duties, entitles him to claim remuneration for his services by such substitute, not merely from the date of his appointment, but from the day he, with the sanction of the Committee, commenced to discharge the duties.

It thus appears that the right of a board of guardians to "determine the amount of remuneration, if any," in such cases does not relieve them of liability to pay reasonable claims for services rendered and accepted.

(To be continued.)

IRISH POOR-LAW INTELLIGENCE.

FEEs FOR MEDICAL INSPECTORS OF LABOURERS' DWELLINGS IN IRELAND.

THE suit promoted by the Irish Medical Association to establish the right of Medical Officers of Health throughout Ireland to be paid for the functions performed by them in connection with the recently-enacted Labourers' Dwellings Act, came to a hearing on Saturday last in the Nisi Prius Court, Dublin, before Mr. Justice Lawson. The Association sued on behalf of Dr. Rogers, of Youghal, who had inspected over eighty cabins within his district upon a general order from his board of guardians. He had expended many days in the work, lamed a horse, travelled over dozens of miles of mountain road, attended on an expedition for fixing sites for new buildings, and afterwards presented himself at the board of guardians to answer questions on the subject. When he asked for his remuneration, the guardians declined to pay him a single shilling, either for his work or his travelling expenses, grounding their refusal upon the theory that his salary as Medical Officer of Health covered the duties. As a matter of fact, the year's salary was only £18, for which multifarious duties had been always discharged, irrespective of the inspections in question, which were entirely new, and not thought of when the duties and emoluments of the Medical Officer were fixed. Being met with this refusal, Dr. Rogers appealed to the Local Government Board, but—as might be expected—in vain. That Board did not order the guardians to pay, nor even advise them to do so; nor did it tell them that they were *not* to pay, because the work was part of the duty of the Medical Officer. As is its wont, whenever it is called upon to arbitrate between the officer and his masters, the Local Government Board tried to shirk all responsibility by saying as little as possible and doing nothing at all, and, as it is accustomed to do, it left the question to be fought out by a law suit, involving much delay, some bad blood, and great inevitable waste of money to all concerned.

When the suit was commenced by the Association, it

was expected that the Youghal Guardians, having no defence to make save the construction of the Acts of Parliament and the regulations, would take issue on the point of law and allow the question of the liability of the officer for these duties to be argued before the full court on a demurrer, but for some incomprehensible reason this course was not pursued, and the hearing of the case on Saturday last was before a jury. Mr. Lloyd, the solicitor of the Association, had retained Mr. John Gibson, Q.C., and Mr. Price, while the Youghal Guardians were represented by Mr. G. Waters. The evidence of Dr. Rogers as to the work done by him and the authority under which he performed it having been given, the defendants offered no testimony, and attempted no cross-examination. Mr. Justice Lawson, therefore, at once directed a verdict for the plaintiff for the full amount claimed. This decided the question of the reasonableness of the charges made by Dr. Rogers, but did not touch the point of law, for the arguing of which, if the Guardians think it necessary, leave was reserved to them to apply within one week to turn the verdict into one for them.

If they should make this application, it will be in the form of a motion for a conditional order, which, as the plaintiff will not be represented on the occasion, will probably be granted. If so, the real argument will be heard on the motion to make this conditional order absolute probably within the next three weeks. So far, the judgment is in favour of the Irish Medical Association, and, unless the Guardians disturb the verdict within a week, the rights of the Medical Officers of Health in Ireland will have been thereby established.

CORRESPONDENCE.

POOR-LAW MEDICAL OFFICERS AND THE MAGISTRACY.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—The Poor-law medical officers—a very numerous and influential body—confidently look to you and Dr. Lyons, M.P., as their champions and watchful protectors

against any insults or injustices heaped on them, not to allow the Chief Secretary to have the recent insult to an honorable profession rest on it like a loadstone without a vigorous and earnest effort to remove it. I know Dr. Lyons (whose name as a Dublin consultant is familiar with nearly every dispensary doctor in Ireland) is not to be put off by any "placebos" from any member of the Government, and consequently we are sanguine he will successfully fight out this point. I myself could have been a magistrate many years ago. I would not accept the office; but am I to be told by a Liberal Government, who had my political support for many long years, that because I am a member of the profession of medicine, and a graduate of a university, I am not one on whom (if I desired it) the Commission of the Peace would be conferred, though my father and brother, not members of any profession, had been at once appointed magistrates. It is a sting sent deeply into the vitals of every dispensary doctor in Ireland, and the greatest insult ever thrown on him.

Yours, &c.,

A DISPENSARY DOCTOR.

VACCINATION DEFAULT IN IRELAND.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—On the 1st of April ult. I sent to the board of guardians a list of defaulters under the Vaccination Act containing 120 names. Instead of at once summoning the defaulters the board directed their relieving officer to call on every one of them and request to have the children vaccinated without delay. Whether this was done or not, all I know is that only ten of those defaulters' children were vaccinated within the ensuing four weeks. I have a communication before me this day asking me to send again a new list of the parties with unvaccinated children over three months old. Now I have said this before, and I ask you, am I obliged to supply supplementary lists of defaulters every time the guardians apply for them? Is it a part of my business to do so? I have been under the impression that lists of defaulters were only to be supplied once a quarter. The fact of the matter is that vaccination as carried out in this union is a systematic humbug. There are children from 9 months to 4 years not yet vaccinated, and all this because the guardians will not do their duty and prosecute defaulters instead of sending their relieving officer to beg of them to have their children vaccinated. Moreover, I can hardly get any one to bring back their children on the eighth day for inspection. I supplied a list of those persons to the board, and stated that unless they were summoned I could not carry out efficiently the Vaccination Acts for want of fresh pure lymph. The action of the board was in this instance characteristic, they made an order that I summon the defaulters myself and prosecute them at my own expense, which I need scarcely say I objected to do. When will an inspector of vaccination be appointed in this country? Not I suppose until an epidemic of small-pox brings the Local Government Board to a sense of its duty. An easy and prevalent method of carrying out the Compulsory Vaccination Act is to transfer from the register of births the names of every child in that book into the register of successful vaccination, although the practitioner has never seen a single child. Believe me, Sir, that more than one efficient inspector of vaccination will find plenty of work to correct the abuses to which I refer. The defaulters consist of guardians themselves, their relations and defendants, hence their objection to prosecution. I consider it a very bad mode of doing business to summon defaulters in batches. I once knew a doctor who was witness against some twenty defaulters. On leaving

the Court he was greeted with a storm of hisses, and pursued by a threatening crowd through the town. He will not be in a hurry again to appear as a witness. The remedy for this state of things is: 1st. Let an inspector of vaccination be appointed for each province; 2nd. Let the Local Government Board take prosecutions altogether from the guardians into their own hands. Let the dispensary doctor report to the Local Government Board the name of every child when over three months old and not vaccinated, and let the defaulter be summoned forthwith. Of course the expense of prosecution incurred should come from the Local Government Board and not from the guardians. This is the plan adopted by the Registrar-General and it works well, in fact as Registrar I have very little trouble in doing the business of registration to my satisfaction, but between boards of guardians unwilling to carry out their duties, and screaming mammas unwilling to have their children vaccinated within three months, I am fairly pestered.

A DISPENSARY HACK.

[Our correspondent's suggestion as to the transfer of the vaccination jurisdiction from the guardians to the Local Government Board, is an excellent one, and should meet most of the difficulties of which he complains but there is not a shadow of a chance of the suggestion, being adopted. The Local Government Board neither desire the responsibility, nor would accept the duty, preferring to earn their money easy without troubling themselves with such matters as small-pox epidemics. The guardians also would raise a howl if it were proposed to strip them of any prerogative, no matter how irksome or expensive the performance of the duty might be. We do not believe the statement of our correspondent that "an easy and prevalent method of carrying out the Compulsory Vaccination Act, is to transfer from the register of births the name of every child in that book into the register of successful vaccinations, although the practitioner has not seen a single child of them." To do so would be roguery, well deserving and likely to result in condign punishment. But we fear that a very large percentage of the vaccinations paid for, are altogether unsatisfactory and inefficient because of the most reprehensible carelessness of the Local Government Board and their refusal to allow inspectors to be appointed.—ED.]

IRISH MEDICAL ASSOCIATION.

ANNUAL GENERAL MEETING,

JUNE 2, 1884.

REPORT OF COUNCIL

For the Year ending 31st May, 1884.

(Continued.)

SANITARY PROSECUTIONS.

In the last issued periodical report (p. 305) reference was made to a case in which a medical officer of health claimed a fee for attending at court, by direction of his sanitary authority, and giving his evidence in a case of prosecution under the Public Health Act, which had been heard of Newry Quarter Sessions on the 25th January last.

The case was then adjourned to admit of proof being produced as to the liability of the sanitary authority to

pay the fee claimed. At the adjourned hearing of the case the Local Government Board's order of 11th November, 1878 (under section 258 of the Public Health Act), was brought up to prove that the medical officer of health was entitled to remuneration from the sanitary authority, as he had, at their request, given his evidence in the case.

The "order" referred to is thus worded:—

To the Sanitary Authority of each of the Urban Districts; and to the Sanitary Authority of each of the Rural Districts in Ireland; and to all persons whom it may concern:

WHEREAS, under the "Public Health (Ireland) Act, 1878," Ireland is divided into Urban Sanitary Districts and Rural Sanitary Districts, as described in the said Act, respectively:

And whereas with respect to the appearance of sanitary authorities in legal proceedings it is provided in the said Act as follows:—

Section 257.—"Any sanitary authority may appear before any court, or in any legal proceeding by their clerk, or by any officer or member authorised generally or in respect of any special proceeding by resolution or such authority, and their clerk, or any officer or member so authorised, shall be at liberty to institute and carry on under this Act."

Section 258.—"Every officer of a sanitary authority shall attend and assist in any prosecution instituted by such authority on receipt of an order from such authority so to attend: Provided always, that if a medical officer of the sanitary authority shall so attend and assist, he shall be entitled to remuneration from the sanitary authority at such rate as the Local Government Board shall approve, unless it shall have been agreed that the duty of affording such attendance and assistance shall be included in his salary, or that his whole time shall be occupied in the discharge of the duties of his office; and such payment shall be deemed to be expenses incurred by the sanitary authority under this Act, and may be recovered as part of the costs of the prosecution."

Now therefore, We, the Local Government Board for Ireland, do hereby, in any case falling within the provisions recited, approve of such rate of remuneration, not less than one pound and one shilling, and not exceeding two pounds and two shillings per day or part of a day, and may be fixed by the sanitary authority in each case of legal proceeding as aforesaid.

Sealed with our Seal, this Eleventh day of November, in the Year of our Lord One Thousand Eight Hundred and Seventy-eight.

(Signed,)

A. POWER.

R. M. BELLEW.

CHARLES CROKER KING.

MARLBOROUGH,

I, JOHN WINSTON, DUKE OF MARLBOROUGH, Lord Lieutenant General and General Governor of Ireland, do hereby approve this Order.

By Command of His Grace,
HENRY ROBINSON.

On behalf of the sanitary authority the ingenious argument was put forth that, inasmuch as the Local Government Board's order did not definitely and precisely fix the amount of fee payable in such cases, but gave the sanitary authority power to determine the exact amount of the fee, which was to be not less than one guinea nor more than two guineas for each day or part of a day in each case; and as the sanitary authority had not fixed the exact amount of the fee, and positively declined to do so, the sanitary authority, therefore, was not technically liable to pay the exact amount of fee

claimed. A fee was, no doubt, payable, but whether it was to be one guinea or two guineas, or at what intermediate sum the amount of the fee was to be definitely fixed, appeared to be too difficult a problem to be decided at law, and the judge, accordingly, further adjourned the hearing of the case for the purpose of affording an opportunity to have the necessary steps taken to fix the precise amount of the fee payable.

Your council thereupon informed the Local Government Board of this ludicrous "dead-lock," and requested that whatever steps might be necessary to ensure due respect for their order, and justice to the medical officer of health, not only respecting this but all future cases, shall be taken as early as possible.

THE BRANCH SYSTEM.

In the *Ad Interim* report of 12th of February last, your council stated the steps taken to ascertain the opinions of the members of the Association individually concerning the advisability of forming local branches of the Association throughout the provinces, and also the result of the voting, which was—

In favour of the proposal	38
Against it	206

Adverse majority ...	168
----------------------	-----

Only 303 members voted on the question, of whom 57 were doubtful, and two voting papers were spoiled. With an adverse majority of more than 5 to 1, your council consider this question settled in the negative.

MEDICAL MAGISTRATES.

The anxious attention of your council has been directed to the exclusion of dispensary medical officers from the Commission of the Peace in Ireland, which was recently brought under the notice of the House of Commons by Mr. Sexton, M.P., in connection with the case of Dr. Flannery, of Tubbercurry. The council had been aware that a previous Lord Chancellor was stated to have laid down a rule in the year 1872 that dispensary medical officers should not be appointed to the magistracy, but, being also aware that that rule, if it existed, had been departed from subsequently in several instances, they regarded it as abrogated, and, therefore, did not take any step to cause it to be repealed.

When the rule was again enunciated by the Chief Secretary, in reply to Mr. Sexton, M.P., the council thought it necessary to take action, and therefore requested the President to communicate with Mr. Sexton on the subject. The matter was subsequently taken up by Dr. Lyons, M.P., with whom also the President had several communications, and questions were put by him to the Chief Secretary which elicited the fact that the rule in question has no actual existence, that it was the arbitrary decision of a late Lord Chancellor, was in no way binding on his successors, had been broken in numerous instances since his lordship ceased to hold office, and, furthermore, that no similar rule exists in England or elsewhere.

Dr. Lyons, M.P., has given notice that he will call the attention of the House to the subject after the Whitsuntide recess, and the council, in order to strengthen his hands, have prepared a memorial, which is laid on the table to-day, and will be forwarded to each dispensary medical officer for signature as soon as possible. The council, upon inquiry, and upon consideration of the arguments adduced, have not been able to discover any valid reason whatever for the exclusion of dispensary medical officers from the magistracy, and, being aware that the duties have been discharged with perfect propriety, and without the least inconvenience to the public service by those medical officers who have held Her Majesty's commission, they are determined to use every influence to cause this most unnecessary, unwise, and derogatory exclusion to cease.

ROYAL MEDICAL BENEVOLENT FUND FOR IRELAND.

ON Monday, the 2nd inst., the annual meeting of the Royal Medical Benevolent Fund Society of Ireland was held in the College of Physicians, Kildare Street, Dr. WILLIAM MOORE, President of the College, in the chair.

Dr. John William Moore, hon. sec., read the report of the Central Committee, which we shall publish in our next.

Dr. James Little moved the first resolution—"That the report now read, together with the treasurer's financial statement as audited, be received and adopted, and that 1,500 copies of same be printed for circulation." He was surprised to find that they had not a larger meeting, but thought that probably the fact that it was being held in that room had something to do with it, for he had found that their meetings held in the College of Surgeons were always better attended, but perhaps those gentlemen who attended there had matters of greater interest to attract them. As long ago as 1852 he remembered meetings of the Society being held in Sir Patrick Dun's Hospital, when a much larger number of members of the profession attended, but at that time the Society did not rest upon the secure foundation which it did at present; and he fancied that some of their friends thought that the Society's position was one of such security that their countenance was of no importance. He hoped, however, that the idea would not prevail. They required the individual interest of all medical men throughout Ireland. He thought, considering the deplorable state of the country at the present time, that the financial condition of the Society was extremely satisfactory. No class of men, except the unfortunate landlords themselves, had suffered more than the medical men. He observed that the amount of money distributed amongst the medical men was, as compared with the grants to widows and orphans, very small, and he hoped that this was due to the recent legislative measures, which gave medical men the aid which they had a right to expect, and so not render it necessary for them to come to the Society.

Dr. Clarendon seconded the resolution, which was adopted.

Dr. Hemphill moved the second resolution—"That this meeting desires to convey its warmest thanks to the committee and officers of the parent society, as well as those of the provincial and Indian branches, for their hearty zeal in the Society's beneficent work, and also to those of our student brethren who have contributed a tangible proof of their generous sympathy in the cause." He thought it was a privilege to work in aid of such a Society, and he thought that the great success of the Society was due entirely to its officers. Speaking of the provincial branches, as he happened to be a provincial treasurer, he could not but express his sorrow, and regret, and shame that he had had to send such a small sum from the great county of Tipperary, and he also felt ashamed to ask influential patients to subscribe to the Society, when out of nearly one hundred medical men in the county he had hardly ten on his list of subscribers, and he believed that in the northern portion of the county very few sent their names in at all. With respect to the Indian branches, the increase of the subscriptions was certainly a very great cause for congratulation, as was also the hearty co-operation of the members of the Army Medical Department there. The support accorded by the students was also a pleasing feature. They were young men who had plenty to do with what money they had, and he thought the Society should feel very grateful to them for their contributions.

Dr. Barton seconded the resolution. He considered that the officers of the society were deserving of their warmest thanks. There were many difficulties, dis-

couragements perhaps, in collecting the funds, but it was very encouraging to see their distant friends and their students taking up the matters, and they had great matter for congratulation in the past as well as hope for the future. He thought the society deserved their highest approval, not only for the positive good and aid which it gave to those who required it owing to adverse fortune, but directly and distinctly, because it aided in maintaining a proper professional tone in their body. They had heard a great deal about medical legislation, and by many of their English brethren it was supposed that the Medical Bill at present before Parliament would be the means of benefiting the profession; but, looking at it from an Irish stand-point, no good would arise from it, but rather injury; and he believed that all the medical legislation which had taken place had tended to lower their profession rather than otherwise, and he held that it was the duty of the more successful members to assist in maintaining the proper position of their poorer brethren. He thought the executive of those who took part in the work in the country were deserving of the warmest thanks, and the Society, and it was to the co-operation of the medical men in the country to whom they to strengthen the Society in the future.

The resolution was then put to the meeting, and passed unanimously.

Dr. Moloney (Tulla) proposed the third resolution—"That the committee feel it their duty to urge strongly upon the profession that even a moderate annual contribution to this fund would enable them to assist more adequately our necessitous brethren and their families." He believed that the Society had certainly had a fair share of success in the past, but this success was owing to the generosity of a small number of the members of the profession. The resolution was one which should commend itself to all, and he hoped every member of their body in Ireland would act upon it.

Dr. Grimshaw (Registrar-General) said he found that there were 2,500 medical men in Ireland, and Dr. Benson had informed him that the Society had only 500 subscribers, about one-fifth of the entire number. If every one of the 2,000 non-subscribers would subscribe 2s. it would amount to a considerable sum of money, and it was to the annual subscribers that they should look to support the Society rather than to the accumulation of funds.

Dr. Kenny suggested that Dr. Grimshaw's observations should be printed on slips, and copies forwarded to the 2,000 non-subscribers.

Dr. Finny expressed his approval of this scheme.

Dr. Edward Hamilton proposed the election of officers and committee for the ensuing year, and referred in feeling terms to the sudden death of Dr. James Stannus Hughes, of whom he said it was not his place to speak of his merits, but he could say that as a professional gentleman Dr. Hughes was quiet, gentle and courteous, and beloved by all with whom he came in contact. (Hear, hear.)

Dr. Kinkead seconded the resolution, which was adopted.

Dr. Henry King proposed the fifth resolution, "That this meeting thankfully acknowledges the support which our Society has always received from the Press, and confidently relies on a continuance of the same."

Dr. J. Bellew Kelly seconded, and the resolution was passed.

On the motion of Dr. Wharton.

The second chair was taken by Dr. Corley, Vice-President Royal College of Surgeons.

Dr. Wharton then proposed a vote of thanks to the chairman, which was seconded by Dr. Darby, and passed with acclamation.

Dr. Moore having briefly responded,

The proceedings terminated.

D

ROYAL MEDICAL BENEVOLENT FUND FOR IRELAND.

ON Monday, the 2nd inst., the annual meeting of the Royal Medical Benevolent Fund Society of Ireland was held in the College of Physicians, Kildare Street, Dr. WILLIAM MOORE, President of the College, in the chair.

Dr. John William Moore, hon. sec., read the report of the Central Committee, which we shall publish in our next.

Dr. James Little moved the first resolution—"That the report now read, together with the treasurer's financial statement as audited, be received and adopted, and that 1,500 copies of same be printed for circulation." He was surprised to find that they had not a larger meeting, but thought that probably the fact that it was being held in that room had something to do with it, for he had found that their meetings held in the College of Surgeons were always better attended, but perhaps those gentlemen who attended there had matters of greater interest to attract them. As long ago as 1852 he remembered meetings of the Society being held in Sir Patrick Dun's Hospital, when a much larger number of members of the profession attended, but at that time the Society did not rest upon the secure foundation which it did at present; and he fancied that some of their friends thought that the Society's position was one of such security that their countenance was of no importance. He hoped, however, that the idea would not prevail. They required the individual interest of all medical men throughout Ireland. He thought, considering the deplorable state of the country at the present time, that the financial condition of the Society was extremely satisfactory. No class of men, except the unfortunate landlords themselves, had suffered more than the medical men. He observed that the amount of money distributed amongst the medical men was, as compared with the grants to widows and orphans, very small, and he hoped that this was due to the recent legislative measures, which gave medical men the aid which they had a right to expect, and so not render it necessary for them to come to the Society.

Dr. Clarendon seconded the resolution, which was adopted.

Dr. Hemphill moved the second resolution—"That this meeting desires to convey its warmest thanks to the committee and officers of the parent society, as well as those of the provincial and Indian branches, for their hearty zeal in the Society's beneficent work, and also to those of our student brethren who have contributed a tangible proof of their generous sympathy in the cause." He thought it was a privilege to work in aid of such a Society, and he thought that the great success of the Society was due entirely to its officers. Speaking of the provincial branches, as he happened to be a provincial treasurer, he could not but express his sorrow, and regret, and shame that he had had to send such a small sum from the great county of Tipperary, and he also felt ashamed to ask influential patients to subscribe to the Society, when out of nearly one hundred medical men in the county he had hardly ten on his list of subscribers, and he believed that in the northern portion of the county very few sent their names in at all. With respect to the Indian branches, the increase of the subscriptions was certainly a very great cause for congratulation, as was also the hearty co-operation of the members of the Army Medical Department there. The support accorded by the students was also a pleasing feature. They were young men who had plenty to do with what money they had, and he thought the Society should feel very grateful to them for their contributions.

Dr. Barton seconded the resolution. He considered that the officers of the society were deserving of their warmest thanks. There were many difficulties, dis-

couragements perhaps, in collecting the funds, but it was very encouraging to see their distant friends and their students taking up the matters, and they had great matter for congratulation in the past as well as hope for the future. He thought the society deserved their highest approval, not only for the positive good and aid which it gave to those who required it owing to adverse fortune, but directly and distinctly, because it aided in maintaining a proper professional tone in their body. They had heard a great deal about medical legislation, and by many of their English brethren it was supposed that the Medical Bill at present before Parliament would be the means of benefiting the profession; but, looking at it from an Irish stand-point, no good would arise from it, but rather injury; and he believed that all the medical legislation which had taken place had tended to lower their profession rather than otherwise, and he held that it was the duty of the more successful members to assist in maintaining the proper position of their poorer brethren. He thought the executive of those who took part in the work in the country were deserving of the warmest thanks, and the Society, and it was to the co-operation of the medical men in the country to whom they to strengthen the Society in the future.

The resolution was then put to the meeting, and passed unanimously.

Dr. Moloney (Tulla) proposed the third resolution—"That the committee feel it their duty to urge strongly upon the profession that even a moderate annual contribution to this fund would enable them to assist more adequately our necessitous brethren and their families." He believed that the Society had certainly had a fair share of success in the past, but this success was owing to the generosity of a small number of the members of the profession. The resolution was one which should commend itself to all, and he hoped every member of their body in Ireland would act upon it.

Dr. Grimshaw (Registrar-General) said he found that there were 2,500 medical men in Ireland, and Dr. Benson had informed him that the Society had only 500 subscribers, about one-fifth of the entire number. If every one of the 2,000 non-subscribers would subscribe 2s. it would amount to a considerable sum of money, and it was to the annual subscribers that they should look to support the Society rather than to the accumulation of funds.

Dr. Kenny suggested that Dr. Grimshaw's observations should be printed on slips, and copies forwarded to the 2,000 non-subscribers.

Dr. Finny expressed his approval of this scheme.

Dr. Edward Hamilton proposed the election of officers and committee for the ensuing year, and referred in feeling terms to the sudden death of Dr. James Stannus Hughes, of whom he said it was not his place to speak of his merits, but he could say that as a professional gentleman Dr. Hughes was quiet, gentle and courteous, and beloved by all with whom he came in contact. (Hear, hear.)

Dr. Kinkead seconded the resolution, which was adopted.

Dr. Henry King proposed the fifth resolution, "That this meeting thankfully acknowledges the support which our Society has always received from the Press, and confidently relies on a continuance of the same."

Dr. J. Bellew Kelly seconded, and the resolution was passed.
